INTEGRAL CALCULUS.

Integral
Calculus.

Part III.

(110.) WE have supposed hitherto, in our consideration of the Differential and Integral Calculus, that the values of the differential coefficients of the sought functions were explicitly given in terms of the variables. We shall now proceed with the Integration of Differential Equations, and the investigation of the case in which we are to determine the values of the required functions, or rather the relations between the variables and the functions, from given relations, expressed by means of equations, between the variables, the functions themselves, and their differential coefficients. We shall consider this problem as completely resolved when we have reduced them to the determination of the functions by means of the values of their differential coefficients explicitly expressed in terms of the variables. The means of arriving at these reductions have as yet been discovered for a very limited number of cases. Among these, we can only mention here the most general and remarkable.

(111.) The simplest case is that in which it is required to find the relation between x and y , from a given equation between x , y and the first differential coefficient $\frac{dy}{dx}$. Such an equation is called a differential equation of the first order.

The equation between x and y which expresses the required relation is called, as it has been already stated, the integral of the proposed differential equation, and to integrate a differential equation, or to perform its integration, consists in the operation by means of which the integral is obtained.

Let us first suppose that $\frac{dy}{dx}$ enters the given equation algebraically. Its most general form may then be represented by the following equation,

$$\frac{dy^n}{dx^n} + P \frac{dy^{n-1}}{dx^{n-1}} + Q \frac{dy^{n-2}}{dx^{n-2}} + \dots T \frac{dy}{dx} + V = 0 \dots (a)$$

in which $P, Q, \dots, T, V$ may be any functions of x and y .

If $p_1, p_2, p_3, \dots, p_n$ represent the n values of $\frac{dy}{dx}$, derived from this equation, it may be put under the

form
$$\left(\frac{dy}{dx} - p_1\right) \left(\frac{dy}{dx} - p_2\right) \left(\frac{dy}{dx} - p_3\right) \dots \left(\frac{dy}{dx} - p_n\right) = 0.$$

Hence, if $f(x, y) = c$ is the integration of the equation $\frac{dy}{dx} p_1 = 0$, or of any other, formed by making equal to nothing one of the other factors, it will also be the integral of equation (a), since by differentiating $f(x, y) = c$, and substituting the value of $\frac{dy}{dx}$ obtained by this differentiation into the left side of (a) it will

reduce it to nothing. Thus it appears that in the supposition that the decomposition of the left side of (a) into factors may always be effected, the difficulty of integrating (a) is reduced to the integration of an equation of

the form $\frac{dy}{dx} - p_1 = 0$, in which p_1 may be any function of x and y . We shall, therefore, first examine the cases in which this integration may be effected.

(112.) Let $p_1 = -\frac{M}{N}$, the equation $\frac{dy}{dx} - p_1 = 0$ will become $M dx + N dy = 0$; under this form we see that if M and N are such that $\frac{dM}{dy} = \frac{dN}{dx}$, the left side will be the immediate differential of a function of two variables, which function may be found by the rules previously given. Let $f(x, y)$ be that function, then it is obvious that $f(x, y) = c$, c being an arbitrary constant will be the integral of the proposed differential equation; since by differentiating $f(x, y) = c$, we shall obtain a value for $\frac{dy}{dx}$ which will satisfy the equation $M dx + N dy = 0$.

Example. Let $(\sin y + y \cos x) dx + (\sin x + x \cos y) dy = 0$ be the proposed equation. Here $M = \sin y + y \cos x$ and $N = \sin x + x \cos y$, hence

$$\frac{dM}{dy} = \cos y + \cos x = \frac{dN}{dx};$$

therefore the left side may be considered as the immediate differential of a function of two variables; and by applying the known rules, we shall find that function equal to $x \sin y + y \sin x$, therefore the integral of the proposed equation is

$$x \sin y + y \sin x = c.$$

(113.) If M is a function of x alone, and if N contains only y , then it is obvious that the above criterion of integrability is satisfied, since $\frac{dM}{dy}$ and $\frac{dN}{dx}$ are both equal to nothing, and in that case the integral is clearly

$$\int M dx + \int N dy = c.$$

(114.) A very simple transformation will enable us to reduce to the preceding case the equation $M dx + N dy = 0$, if M be a function of y alone, and N a function of x ; or if, more generally, $M = PQ$, and $N = P'Q'$, P and P' being two functions of x , and Q and Q' two functions of y . In the first case, we shall divide both sides of the equation by MN , and in the second case by $Q P'$, and we shall obtain

$$\frac{dx}{N} + \frac{dy}{M} = 0 \quad \text{and} \quad \frac{P dx}{P'} + \frac{Q' dy}{Q} = 0.$$

In both of which the coefficient of dx contains only x , and that of dy only y . When a differential equation is reduced to such a form, the variables are said to be separated, and the integration of it is reduced to the determination of the integrals of the two terms of which it is composed.

(115.) This separation of the variables may easily be effected in some cases.

When M and N are homogeneous functions of x and y , it will be sufficient to assume $y = ux$, or $x = uy$, as may appear most convenient from the form of the equation. By this substitution M and N will become divisible by a power of x or y equal to their common degree, and be reduced to functions of u alone. Let $\phi(u)$ and $\psi(u)$ be those two functions, corresponding to the substitution $y = ux$, then the equation $M dx + N dy = 0$ will be transformed into

$$\phi(u) dx + \psi(u) (u dx + x du) = 0,$$

or

$$\frac{dx}{x} + \frac{\psi(u) du}{\phi(u) + \psi(u) \cdot u} = 0,$$

in which the variables are separated.

Example 1. Let $x dy - y dx = dx \sqrt{x^2 + y^2}$ be the proposed equation. We shall assume $y = ux$, and we shall get

$$x(u dx + x du) - ux dx = x dx \sqrt{1 + u^2}, \quad \text{or} \quad \frac{dx}{x} = \frac{du}{\sqrt{1 + u^2}},$$

integrating we have

$$lx = l(u + \sqrt{1 + u^2}) + c,$$

and putting now $\frac{y}{x}$ for u , we obtain $lx = l\left(\frac{y + \sqrt{x^2 + y^2}}{x}\right) + c$, or putting for the constant le , and reducing,

$$x^e = e^c + 2cy.$$

Example 2. Let the differential equation be $x dy - y dx = y l\left(\frac{y}{x}\right) dx$. We shall make $y = ux$, and we shall find successively

$$x(u dx + x du) - ux dx = u x l u dx,$$

$$\frac{dx}{x} = \frac{du}{u l u}, \quad lx = ll u + e = l(c l u),$$

$$x = c l u, \quad e^x = u^c = \left(\frac{y}{x}\right)^c, \quad \text{or } y^c = x^c e^x.$$

Example 3. Let the proposed equation be

$$(a + b x + c y) dx = (a' + b' x + c' y) dy.$$

In this case the coefficients of dx and dy are not homogeneous functions, but if we assume $x = e + x'$, and $y = f + y'$, e and f being two undeterminate quantities, they may be determined by the condition that in the transformed equation the constant parts of the coefficients dx and dy will vanish, and the transformed equation be, therefore, an homogeneous equation. The values of e and f satisfying these conditions, will be given by the two equations

$$a + b e + c f = 0, \quad a' + b' e + c' f = 0.$$

If $b c' = b' c$, the expressions for e and f become infinite; but in that case $b' x + c' y = \frac{c'}{c} (b x + c y)$, and consequently the equation becomes

$$a dx - a' dy + (b x + c y) \left(dx - \frac{c'}{c} dy \right) = 0.$$

It is sufficient to make in this equation $b x + c y = t$ to separate the variables, for then $dy = \frac{dt - b dx}{c}$, and these values being substituted give

$$dx = \frac{(a' c + c' t) dt}{a c^2 + a' b c + (c^2 + c' b) t}.$$

The integral of the right side of this equation will in general contain logarithms, except when $c^2 + c' b = 0$, in which case we have clearly

$$x = \frac{2 a' c t + c' t^2}{2 (a c^2 + a' b c)} + C.$$

Example 4. In some cases a similar method may be used to reduce to homogeneity equations more complicated than the preceding. Let

$$(6 x^2 - 4 x y + 2 y^2 - 4 x + 4 y + 2) dy + (3 x^2 + 5 y^2 + 10 y + 5) dx = 0$$

be the proposed equation; assume

$$x = m t + n u + p, \quad \text{and } y = m' t + n' u + p',$$

m, n, p, m', n', p' being undeterminate quantities the values of which are to be found by the condition that the coefficients of dt and du in the transformed equation will be homogeneous functions; that is to say, will not contain the first powers of t and u , nor any term constant. There are, therefore, six conditions and six quantities; but the equations which will express these conditions will be of a degree higher than the first, and therefore may lead to imaginary values for m, n, p, m', n', p' . In this example they are real, and we have

$$m = 1, \quad n = 1, \quad p = 1, \quad m' = 1, \quad n' = -1, \quad p' = -1.$$

The corresponding values of x and y being substituted, reduce the proposed equation to

$$(3 t^2 + t u + 5 u^2) dt + (t^2 - 3 t u - u^2) du = 0,$$

which is homogeneous, and in which the variables may readily be separated, as in the preceding examples.

(116.) The differential equations included under the form $\frac{dy}{dx} + P y = Q$, in which P and Q are functions of x alone, and which contains only the first power of the function y , and its first differential coefficient $\frac{dy}{dx}$, is called a linear equation of the first order. It may be easily integrated, by first separating the variables in the following manner.

The method employed is founded upon the propriety of the function e^x having its differential coefficient equal to the function itself multiplied by dx . Hence, $d e^{f P dx} = e^{f P dx} \cdot P dx$; therefore, if in the proposed equation $dy + P y dx = Q dx$, we assume $y = z e^{-f P dx}$, we shall have $dy = -z e^{-f P dx} \cdot P dx + e^{-f P dx} \cdot dz$; and these values being substituted, the first term of the value of dy will destroy the term $P y dx$, and the equation will be reduced to

$$e^{-f P dx} \cdot dz = Q dx, \quad \text{or } dz = e^{f P dx} \cdot Q dx,$$

in which the variables are separated. Integrating, we get

$$z = \int e^{f P dx} \cdot Q dx + c;$$

and, consequently,

$$y = e^{-f P dx} \left(\int e^{f P dx} \cdot Q dx + c \right).$$

Example 1. Let $dy = (a + b x + c y) dx$ be the proposed equation.

In this case

$$P = -c \text{ and } Q = (a + b x),$$

therefore

$$y = e^{cx} \left(\int e^{-cx} (a + b x) dx + c \right),$$

or

$$y = -\frac{a}{c} - \frac{b x}{c} - \frac{b}{c^2} + C e^{cx}, \text{ or } C e^{cx} = b + c(a + b x + c y).$$

Example 2. Let the proposed equation be

$$dy + y \frac{x dx}{1 - x^2} = \frac{a dx}{1 - x^2},$$

here

$$P dx = \frac{x dx}{1 - x^2} \text{ and } \int P dx = -\frac{1}{2} \log(1 - x^2), \text{ or } e^{\int P dx} = \sqrt{1 - x^2},$$

consequently

$$\int e^{\int P dx} \cdot Q dx + = \frac{ax}{\sqrt{1 - x^2}},$$

and

$$y = ax + e \sqrt{1 - x^2}.$$

(117.) The equation $dy + P y dx = Q y^{n+1} dx$, where P and Q are functions of x only, may easily be transformed into a linear equation of the first order; for if we assume $y = z^{-\frac{1}{n}}$, we get $dy = -\frac{1}{n} z^{-\frac{n+1}{n}} dz$, and $y^{n+1} = z^{-\frac{n+1}{n}}$. These values being substituted, the equation becomes

$$-\frac{1}{n} z^{-\frac{n+1}{n}} dz + P z^{-\frac{1}{n}} dx = Q z^{-\frac{n+1}{n}} dz,$$

and by dividing both sides by $z^{-\frac{n+1}{n}}$, and multiplying by $-n$,

$$dz - n P z dx = -n Q dx.$$

(118.) The more general equation,

$$n x^k y^k dy + m x^g y^h dx = l x^e y^f dx,$$

may also be transformed into a linear equation, when $\frac{h-f}{k-f+1} = 1$; and when the same quantity is equal 2, the variables may be separated, if $\frac{e-g}{g-i+1}$ is of the form $\frac{-4i}{2i \pm 1}$. In order to prove this, we shall

assume

$$y = z^{\frac{1}{k-f+1}} \text{ and } x = u^{\frac{1}{g-i+1}}.$$

Substituting for x and y these values, and those of their differentials dx , dy , which are derived from them, we get

$$dz + \frac{(k-f+1)m}{(g-i+1)n} z^{\frac{h-f}{k-f+1}} du = \frac{(k-f+1)l}{(g-i+1)n} u^{\frac{e-g}{g-i+1}} du.$$

Hence, if $\frac{h-f}{k-f+1} = 1$, the equation is linear. Let us now examine the case when the same quantity is equal 2; and, to simplify, assume $\frac{(k-f+1)m}{(g-i+1)n} = b$, $\frac{(k-f+1)l}{(g-i+1)n} = a$, and $\frac{e-g}{g-i+1} = m$, the last equation becomes

$$dz + b z^2 du = a u^m du.$$

First, when $m = 0$, the variables are immediately separated, and we get

$$\frac{dz}{a - b z^2} = du,$$

and

$$u = \frac{1}{2\sqrt{ab}} \log \left(\frac{\sqrt{a} + z\sqrt{b}}{\sqrt{a} - z\sqrt{b}} \right) + c.$$

If m be not equal to nothing, we shall assume $z = A u^p + u^q$, and we shall get by substitution

$$\left. \begin{aligned} &u^q dz + (q u^{q-1} + 2b A u^{p+q} + b u^{2q} z) z du \\ &+ (p A u^{p-1} + b A^2 u^{2p}) du \end{aligned} \right\} = a u^m du.$$

A , p , and q being indeterminate quantities, we may find values for them which will simplify this equation; it will be reduced to three terms if we have

$$p - 1 = 2p, \quad p A + b A^2 = 0, \quad q - 1 = p + q, \quad \text{and } q + 2b A = 0.$$

We have four equations and only three quantities to dispose of, but the first and third do not really differ from each other; they both give $p = -1$, and this being substituted in the second and fourth, we find $A = \frac{1}{b}$, and

$q = -2$. Therefore the supposition $z = \frac{1}{b u} + \frac{y}{u^2}$ will transform the equation $dz + b z^2 du = a u^m du$

into

$$dz + \frac{b z^2}{u^2} du = a u^{m+2} du.$$

This equation is homogeneous when $m = -2$, and if $m + 2 = -2$ or $m = -4$, the variables are separated; in that case the equation becomes

$$dz + (bz^2 - a) \frac{du}{u^2} = 0, \quad \text{or} \quad \frac{dz}{bz^2 - a} + \frac{du}{u^2} = 0.$$

These are not the only values of m for which the equation $dz + \frac{bz^2 du}{u^2} = a u^{m+2} \cdot du$, may be integrated.

Let now $z = \frac{1}{y}$ and $u^{m+2} = x$; substitute for z , dz , u , and du their values, after reduction we shall find

$$dy + \frac{a}{m+3} y^2 dx = \frac{b}{m+3} x^{-\frac{m+4}{m+3}} dx.$$

This equation has the same form as the equation from which it is derived, therefore it will be integrated by the same means when the exponent of x , or $-\frac{m+4}{m+3}$, will be equal to -2 or -4 ; that is to say, when m

will be equal to -2 or $-\frac{8}{3}$. The first of these two values shows nothing new, but the second is a new value

of m , for which the equation may be integrated.

$$dz + bz^2 du = a u^m du$$

We have thus found four different values of m , for which the integration may be performed; they are

$$m = 0, \quad m = -2, \quad m = -4, \quad m = -\frac{8}{3};$$

there are, besides, an infinite number of others, which may be found by following the same process. If in the

equation
$$dy + \frac{a}{m+3} y^2 dx = \frac{b}{m+3} x^{-\frac{m+4}{m+3}} dx,$$

we suppose $\frac{a}{m+3} = b'$, $\frac{b'}{m+3} = a'$, $-\frac{m+4}{m+3} = m'$, and $y = \frac{1}{y'}$ and $x^{m'+3} = x'$,

we shall get clearly
$$dy' + \frac{a'}{m'+3} y'^2 dx' = \frac{b'}{m'+3} x'^{-\frac{m'+4}{m'+3}} dx',$$

and this equation will be readily integrated when $-\frac{m'+4}{m'+3}$ will be equal to -2 or -4 . It is not necessary to consider the first value, since it corresponds to $m' = -2$, and consequently to $m = -2$; the second gives $m' = -\frac{8}{3}$ and $m = -\frac{12}{5}$.

Generalizing what precedes, we easily see, that, provided one of the terms of the series

$$m - \frac{m+4}{m+3}, \quad -\frac{m'+4}{m'+3}, \quad -\frac{m''+4}{m''+3}, \quad \&c.$$

in which each accented letter is the value of the preceding term, shall be equal to -4 , the equation

$$dz + bz^2 du = a u^m du$$

can be integrated.

To find the general term of this series, let us substitute in the third term for m' its value, that is the second term, and the value thus obtained for m'' in the fourth term; we shall have then for the terms of the series

$$m, \quad -\frac{m+4}{m+3}, \quad -\frac{3m+8}{2m+5}, \quad -\frac{5m+12}{3m+7}, \quad \&c.$$

and observing that in these the coefficients of m , in the numerators, form the series of the odd numbers, beginning with 1, and in the denominator the series of the natural numbers beginning with 1; that the constant parts in the numerators form the series of the successive multiple of 4, and in the denominator the series of the odd numbers beginning with 3; we shall conclude by analogy that the term preceded by i terms will be represented by the following expression,

$$-\frac{(2i-1)m+4i}{im+(2i+1)}.$$

We may verify the correctness of this induction by calculating the value of the following term, according to the general law; and observing that it is equal to the preceding expression, when for i , $i+1$ is substituted. We have for the following term

$$-\frac{\frac{(2i-1)m+4i}{im+2i+1} + 4}{\frac{(2i-1)m+4i}{im+2i+1} + 3} = -\frac{(2i+1)m+4(i+1)}{(i+1)m+2i+3}.$$

Hence the general term is expressed by

$$-\frac{(2i-1)m+4i}{im+2i+1};$$

therefore, according to what has been stated above, the proposed differential equation can be integrated. When the quantity $-\frac{(2i-1)m+4i}{im+2i+1}$ is equal to 0, to -2 , or to -4 . The first supposition gives $m = -$

$\frac{4i}{2i-1}$, the second $m = -2$, and the third $m = -\frac{4(i+1)}{2(i+1)}$. The last value is included in the first,

since it only differs from it by the substitution of $(i+1)$ to i . It results, therefore, from this investigation, that the equation

$$dz + bz^2 du = au^m du$$

can be integrated when m is equal to the expression $-\frac{4i}{2i-1}$, in which i may be nothing, infinity, or any integer

whatever. Moreover, if we make $z = \frac{1}{z'}$,

$$u^{m+1} = u', \quad \frac{a}{m+1} = b', \quad \frac{b}{m+1} = a', \quad -\frac{m}{m+1} = m',$$

the equation will be transformed into

$$dz' + b'z'^2 du' = a'x^{m'} du'.$$

This equation being similar to that from which it is derived may be integrated in the same cases, that is, when

$$m' = -\frac{4i}{2i-1}; \quad \text{but } m' = -\frac{m}{m+1},$$

therefore the equation

$$dz + bz^2 du = au^m du$$

may also be integrated when $-\frac{m}{m+1} = -\frac{4i}{2i-1}$, or when $m = \frac{-4i}{2i+1}$.

This equation was first considered by Count James Ricatti, and is known under the name of Ricatti's equation.

(119.) In many cases, besides the few we have examined, the variables may be separated by substitutions for which no general rule can be given. Numerous examples of these transformations are found in the works of Euler; and many more may be easily formed by assuming a differential equation in which the terms are homogeneous, or the variables separated, and substituting in it for one, or both variables, functions of other variables which will lead to a new differential equation, in which the variables may be separated by inverting the formulæ which have served to obtain it.

Let us take, for instance, the differential equation

$$du \left(1 - \frac{b}{1+u^2} \right) - ay dy = 0,$$

when the variables are separated; assuming $u = xy$, we shall have by substituting for u and du their values, and reducing

$$\{ (x - ay) dy + y dx \} (1 + x^2 y^2) = b (y dx + x dy),$$

which equation is not homogeneous, and in which the variables are not separated. It does not at first sight appear what substitution should be made in this equation to separate the variables; but it is obvious, from the manner

in which it has been obtained, that it is sufficient for that purpose to assume $x = \frac{u}{y}$.

We shall take for another example the equation

$$x dx + dy = m y^{\frac{1}{2}} dx.$$

To make it homogeneous, it will be sufficient to make $y = z^2$; it then becomes

$$x dx + 2z dz = m z dx,$$

assuming $z = tx$ to separate the variables, we find

$$dx + 2t(t dx + x dt) = m t dx,$$

or

$$\frac{dx}{x} + \frac{2t dt}{1 - mt + 2t^2} = 0,$$

or

$$\frac{dx}{x} + \frac{\frac{1}{2}(32t - 8m) dt}{(4t - m)^2 + 8 - m^2} + \frac{4m dt}{(4t - m)^2 + 8 - m^2} = 0,$$

Integral
Calculus.

integrating

$$lx + \frac{1}{2} l \{ 4t - m \}^2 + 8 - m^2 \} + \frac{m}{\sqrt{8 - m^2}} \tan^{-1} \frac{4t - m}{\sqrt{8 - m^2}} = lc,$$

and putting back for t its value $\frac{z}{x} = \frac{y^{\frac{1}{2}}}{x}$, and including $-l\sqrt{8}$ in the constant, we get

$$l \frac{c}{\sqrt{(x^2 - mx\sqrt{y+2y})}} = \frac{m}{\sqrt{8 - m^2}} \tan^{-1} \frac{4\sqrt{y - mx}}{x\sqrt{8 - m^2}}.$$

(120.) It is very remarkable that some equations, in which the variables are separated, admit of algebraical integrals, although the integral of each part considered separately is transcendental. The equation $\frac{dx}{x} + \frac{dy}{y} = 0$, for

instance, has for immediate integral $lx + ly = lc$, from which we deduce from the known properties of logarithmic functions $xy = c$, which is an algebraical equation. In this and some similar cases the algebraical integral may be found without the passage through the transcendental functions. If we multiply both sides of the above differential equation by xy , it becomes $ydx + xdy = 0$, which gives immediately $xy = c$ for its integral. When the algebraical integral may thus be obtained, it is of great importance, especially if the properties of the transcendental function are not known, for then it may be instrumental to discover them.

Let us take for example the differential equation

$$\frac{dx}{\sqrt{(a - bx + cx^2)}} + \frac{dy}{\sqrt{(a + by + cy^2)}} = 0.$$

To obtain an algebraical integral, we shall proceed in the following manner. We shall first square both sides, and we shall get

$$(a + bx + cx^2) dy^2 = (a + by + cy^2) dx^2.$$

If we differentiate this equation twice, we find

$$2 \frac{d^2 y}{dx^2} (a + bx + cx^2) + dy dx (b + 2cx) = dx^2 (b + 2cy),$$

and

$$2 \frac{d^2 y}{dx^2} (a + bx + cx^2) + 3 \frac{d^2 y}{dx^2} dx (b + 2cx) = 0,$$

the last equation, may be put under the following form

$$\frac{2 \frac{d^2 y}{dx^2}}{\frac{d^2 y}{dx^2}} + \frac{3(b + 2cx) dx}{a + bx + cx^2} = 0,$$

which being integrated gives

$$2l \frac{d^2 y}{dx^2} + 3l(a + bx + cx^2) = 2la,$$

a being an arbitrary constant, or

$$\left(\frac{d^2 y}{dx^2} \right)^2 (a + bx + cx^2)^3 = a^2;$$

substituting this value of $\frac{d^2 y}{dx^2}$ in the differential equation of the second order, we shall have

$$\frac{dy}{dx} = \frac{(b + 2cy) \sqrt{(a + bx + cx^2)} - 2a}{(b + 2cx) \sqrt{(a + bx + cx^2)}};$$

putting this value of $\frac{dy}{dx}$ in the proposed differential equation, we get for the integral under an algebraical form

$$(b + 2cy) \sqrt{(a + bx + cx^2)} + (b + 2cx) \sqrt{(a + by + cy^2)} = 2a \dots (1).$$

If we designate now by $f(x)$ the integral of $\frac{dx}{\sqrt{(a + bx + cx^2)}}$, we may represent the same integral by

$$f(x) + f(y) = \beta.$$

Hence we infer this property of the transcendant designated by f , that $f(x) + f(y)$ is equal to a constant when ever x and y are connected together by an equation such as (1).

To arrive at a result easy to verify, let us suppose $a = 1$, $b = 0$, $c = -1$, then the differential equation is

$$\frac{dx}{\sqrt{(1 - x^2)}} + \frac{dy}{\sqrt{(1 - y^2)}} = 0.$$

The integral we have obtained is reduced to

$$y \sqrt{(1 - x^2)} + x \sqrt{(1 - y^2)} = a,$$

and if we designate by $f(x)$ and $f(y)$ the integrals of $\frac{dx}{\sqrt{(1 - x^2)}}$ and $\frac{dy}{\sqrt{(1 - y^2)}}$, we shall have between these

transcendants the relation $f(x) + f(y) = \beta$. The constants a and β are not independent of each other, since one of the equations must be a transformation of the other. To find the relation which exists between them, we shall observe that, according to the first equation, when $y = 0$, $x = a$, substituting these values in the second,

Integral
Calculus.

we get

$$f(a) + f(o) = \beta.$$

But if we develop $\frac{dx}{\sqrt{1-x^2}}$ according to the powers of x , and integrate each term of the developement, it

will become evident that $f(o)$ is equal to nothing, therefore $\beta = f(a)$, and consequently, the two equations are

$$y\sqrt{1-x^2} + x\sqrt{1-y^2} = a, \quad f(x) + f(y) = f(a).$$

Let $f(x) = x'$, $f(y) = y'$, then $x = f^{-1}(x')$, $y = f^{-1}(y')$, $x' + y' = f(a)$, and $a = f^{-1}(x' + y')$. These values being substituted in the first equation, we get

$$f^{-1}(y')\sqrt{1-(f^{-1}(x'))^2} + f^{-1}(x')\sqrt{1-(f^{-1}(y'))^2} = f^{-1}(x' + y').$$

From this equation we could deduce all the properties of the transcendents $f^{-1}(x)$ and $f(x)$. Here these properties are already known, since $f(x) = \int \frac{dx}{\sqrt{1-x^2}} = \sin^{-1} x$, and consequently, $f^{-1}(x) = \sin(x)$; but they are also

derivable from the above equation, which corresponds to the formula

$$\sin y' \cos x' + \sin x' \cos y' = \sin(x' + y').$$

(121.) We shall take for another example the equation

$$\frac{dx}{\sqrt{(a+bx+cx^2+ex^3+fx^4)}} + \frac{dy}{\sqrt{(a+by+cy^2+ey^3+fy^4)}} = 0.$$

To obtain an algebraical integral we shall use a method which may be applied in several analogous cases, and for which we are indebted to Lagrange and Euler.

The process consists in finding another differential equation of the first order, combined with the proposed steps to the required integral.

Let us suppose that x and y are functions of another variable t , and let

$$\frac{dx}{dt} = \sqrt{(a+bx+cx^2+ex^3+fx^4)}, \quad \frac{dy}{dt} = -\sqrt{(a+by+cy^2+ey^3+fy^4)}.$$

If we square both sides of each of these equations, and then differentiate, we find

$$\frac{2d^2x}{dt^2} = b + 2cx + 3ex^2 + 4fx^3, \quad \frac{2d^2y}{dt^2} = b + 2cy + 3ey^2 + 4fy^3,$$

and, by addition, $\left(\frac{d^2x}{dt^2} + \frac{d^2y}{dt^2}\right) = b + c(x+y) + \frac{3}{2}e(x^2+y^2) + 2f(x^3+y^3)$;

making $x+y=p$ and $x-y=q$, we shall get by substitution

$$\frac{d^2p}{dt^2} = b + cp + \frac{3}{4}e(p^2+q^2) + \frac{1}{2}f(p^3+3pq^2).$$

Now from the values of p and q , we get

$$x = \frac{1}{2}(p+q), \quad y = \frac{1}{2}(p-q), \quad \text{and} \quad \frac{dx^2}{dt^2} - \frac{dy^2}{dt^2} = \frac{dpdq}{dt^2};$$

substituting in the last of these equations for $\frac{dx^2}{dt^2}$ and $\frac{dy^2}{dt^2}$ their values, and then for x and y their values in terms of p and q , we shall find

$$\frac{dpdq}{dt^2} = bq + cpq + \frac{1}{4}e(3p^2q+q^3) + \frac{1}{2}f(p^3q+pq^3);$$

this being subtracted from the value of $\frac{d^2p}{dt^2}$ multiplied by q , gives

$$q \frac{d^2p}{dt^2} - \frac{dpdq}{dt^2} = \frac{1}{2}eq^3 + fpq^3,$$

an equation which becomes integrable, when both sides are multiplied by $\frac{2dp}{q^3 dt}$, for it becomes then

$$\frac{2}{q^3} \frac{d^2p}{dt^2} \cdot \frac{dp}{dt} - \frac{2}{q^3} \frac{dp^2}{dt^2} \cdot \frac{dq}{dt} = e \frac{dp}{dt} + 2fp \frac{dp}{dt},$$

and the left side is the differential coefficient of $\frac{dp^2}{q^3 dt^2}$; we shall have, therefore, in integrating

$$\frac{dp^2}{q^3 dt^2} = ep + fp^2 + a^2, \quad \text{or} \quad \frac{dp}{dt} = q\sqrt{(a^2 + ep + fp^2)}.$$

But

$$\frac{dp}{dt} = \frac{dx}{dt} + \frac{dy}{dt} = \sqrt{(a+bx+cx^2+ex^3+fx^4)} - \sqrt{(a+by+cy^2+ey^3+fy^4)};$$

Integral
Calculus.

 substituting this value as well as those of p and q in the preceding equation, we find

$$\sqrt{a+bx+cx^2+ex^3+fx^4} - \sqrt{a+by+cy^2+ey^3+fy^4} = (x-y)\sqrt{a^2+e(x+y)+f(x+y)^2}. \quad (1).$$

If we invert both sides of this equation, and then multiply by

$$(a+bx+cx^2+ex^3+fx^4) - (a+by+cy^2+ey^3+fy^4),$$

we shall obtain

$$\begin{aligned} & \sqrt{a+bx+cx^2+ex^3+fx^4} + \sqrt{a+by+cy^2+ey^3+fy^4} \\ &= \frac{b+c(x+y)+e(x^2+xy+y^2)+f(x^3+x^2y+xy^2+y^3)}{\sqrt{a^2+e(x+y)+f(x+y)^2}}. \end{aligned}$$

This equation being added to the preceding, and then both sides of it raised to the square, we shall have the integral under a rational form,

$$\begin{aligned} & b^2 - 4Aa^2 + (2bc - 4ad - 2ba^2)(x+y) + (c^2 - 4ae - 2ca^2 + a^4)(x^2+y^2) + 2(c^2 - 4ae - bd - a^4)xy \\ & + 2(cd - 2be - da^2)(x+y)xy + (d^2 - 4ea^2)x^2y^2 \} = 0. \end{aligned}$$

This equation is at the same time the integral of

$$\frac{dx}{\sqrt{a+bx+cx^2+ex^3+fx^4}} - \frac{dy}{\sqrt{a+by+cy^2+ey^3+fy^4}} = 0,$$

for the integral of this would first present itself under the form

$$\sqrt{a+bx+cx^2+ex^3+fx^4} + \sqrt{a+by+cy^2+ey^3+fy^4} = (x-y)\sqrt{a^2+d(x+y)+e(x+y)^2};$$

and it is obvious that if we were to deduce from this, by means similar to those used above, the value of the difference of the two radicals, and then by addition the value of the first, we should get precisely the same value we have had before.

 The integral we have obtained becomes $b = a^2$, when the quantity $a+bx+cx^2+ex^3+fx^4$ is a perfect square, that is, when we can suppose

$$a = a'^2, \quad b = 2a'b', \quad c = 2a'c' + b'^2, \quad e = 2b'c', \quad \text{and} \quad f = c'^2.$$

To obtain the integral in that supposition, assume

$$\sqrt{a+bx+cx^2+ex^3+fx^4} = \sqrt{(a'+b'x+c'x^2)^2 + k},$$

and

$$\sqrt{a+by+cy^2+ey^3+fy^4} = \sqrt{(a'+b'y+c'y^2)^2 + k},$$

 and develop the right side of each of these equations, according to the powers of k by the binomial theorem, we shall have

$$\sqrt{(a'+b'x+c'x^2)^2 + k} = (a'+b'x+c'x^2) + \frac{k}{2(a'+b'x+c'x^2)} + \&c.,$$

$$\sqrt{(a'+b'y+c'y^2)^2 + k} = (a'+b'y+c'y^2) + \frac{k}{2(a'+b'y+c'y^2)} + \&c.;$$

 substitute now these values in the general integral, we shall get, after dividing by $(x-y)$,

$$b' + c'(x+y) - \frac{(b' + c'(x+y))k}{2(a'+b'x+c'x^2)(a'+b'y+c'y^2)} = \sqrt{a^2 + 2bc(x+y) + c^2(x+y)^2}.$$

 Raising now both sides to the square, neglecting the square of k , and making $b^2 - a^2 = ka'$, we shall have, after reduction,

$$a'(a'+b'x+c'x^2)(a'+b'y+c'y^2) = \{b' + c'(x+y)\}^2;$$

which, therefore, is the integral under an algebraical and rational form of

$$\frac{dx}{a'+b'x+c'x^2} + \frac{dy}{a'+b'y+c'y^2} = 0.$$

Having thus arrived at the algebraical integral of

$$\frac{dx}{\sqrt{a+bx+cx^2+ex^3+fx^4}} + \frac{dy}{\sqrt{a+by+cy^2+ey^3+fy^4}} = 0,$$

we might, by determining the relation which exists between the constant contained in this integral, and that of the equation

$$\int \frac{dx}{\sqrt{a+bx+cx^2+ex^3+fx^4}} + \int \frac{dy}{\sqrt{a+by+cy^2+ey^3+fy^4}} = \beta,$$

 discover a fundamental property of the transcendant $\int \frac{dx}{\sqrt{a+bx+cx^2+ex^3+fx^4}}$

 (122.) We have already stated that $\int \frac{P dx}{\sqrt{a+bx+cx^2+ex^3+fx^4}}$ may be made to depend upon others,

which by proper transformations may be proved to be all included in the general expression

$$\int \frac{a + b \sin^2 \phi}{c + d \sin^2 \phi} \cdot \frac{d\phi}{\sqrt{(1 - e^2 \sin^2 \phi)}}.$$

Legendre has given to the functions represented by the integrals of this form, the name of elliptical transcendents, because some of them may be expressed by means of arcs of ellipses; he has discovered several remarkable properties of these functions, and deduced from them the means of calculating their approximate values. For all the details of these important investigations, we must refer those who may wish to know them to the work entitled *Exercices de Calcul Intégral*. In the sequel we shall have occasion to return again to this subject; for the present, we shall only determine the integral of the equation

$$\frac{d\phi}{\sqrt{(1 - e^2 \sin^2 \phi)}} + \frac{d\theta}{\sqrt{(1 - e^2 \sin^2 \theta)}} = 0,$$

by the method we have used above, and deduce from it a property of the transcendent $\int \frac{d\phi}{\sqrt{(1 - e^2 \sin^2 \phi)}}$.

We shall assume as before

$$\frac{d\phi}{dt} = \sqrt{(1 - e^2 \sin^2 \phi)}, \quad \frac{d\theta}{dt} = -\sqrt{(1 - e^2 \sin^2 \theta)};$$

squaring and differentiating these equations, we shall find

$$\frac{d^2 \phi}{dt^2} = -e^2 \sin \phi \cos \phi, \quad \frac{d^2 \theta}{dt^2} = -e^2 \sin \theta \cos \theta,$$

and consequently

$$\begin{aligned} \frac{d^2 \phi}{dt^2} + \frac{d^2 \theta}{dt^2} &= -e^2 (\sin \phi \cos \phi + \sin \theta \cos \theta) = -\frac{1}{2} e^2 (\sin 2\phi + \sin 2\theta), \\ \frac{d^2 \phi}{dt^2} - \frac{d^2 \theta}{dt^2} &= -e^2 (\sin \phi \cos \phi - \sin \theta \cos \theta) = -\frac{1}{2} e^2 (\sin 2\phi - \sin 2\theta). \end{aligned}$$

Let $p = \phi + \theta$, and $q = \phi - \theta$, we shall have

$$\phi = \frac{1}{2}(p + q), \quad \theta = \frac{1}{2}(p - q), \quad d^2 \phi + d^2 \theta = d^2 p, \quad d^2 \phi - d^2 \theta = d^2 q;$$

and hence

$$\begin{aligned} \frac{d^2 p}{dt^2} &= -\frac{1}{2} e^2 \{ \sin(p + q) + \sin(p - q) \} = -e^2 \sin p \cos q, \\ \frac{d^2 q}{dt^2} &= -\frac{1}{2} e^2 \{ \sin(p + q) - \sin(p - q) \} = -e^2 \cos p \sin q. \end{aligned}$$

But we have also

$$\begin{aligned} \frac{dp}{dt} \cdot \frac{dq}{dt} &= \frac{d\phi^2}{dt^2} - \frac{d\theta^2}{dt^2} = -e^2 (\sin^2 \phi - \sin^2 \theta) = \frac{1}{2} e^2 (\cos 2\phi - \cos 2\theta) \\ &= \frac{1}{2} e^2 \{ \cos(p + q) - \cos(p - q) \} = -e^2 \sin p \sin q. \end{aligned}$$

If we now divide the values of $\frac{d^2 p}{dt^2}$, $\frac{d^2 q}{dt^2}$, by that of $\frac{dp}{dt} \cdot \frac{dq}{dt}$, we find

$$\frac{d^2 p}{dp dq} = \frac{\cos q}{\sin q}, \text{ or } \frac{d^2 p}{dp} = \frac{dq \cos q}{\sin q}; \text{ and } \frac{d^2 q}{dp dq} = \frac{\cos p}{\sin p}, \text{ or } \frac{d^2 q}{dq} = \frac{\cos p \cdot dp}{\sin p}.$$

These results can be integrated without difficulty, and give

$$l \frac{dp}{dt} = l \sin q + l a, \text{ and } l \frac{dq}{dt} = l \sin p + l a',$$

or, which is the same thing,

$$\frac{dp}{dt} = a \sin q, \text{ and } \frac{dq}{dt} = a' \sin p.$$

The two constants a and a' are not independent of each other, for if we multiply together these two equations we get

$$\frac{dp}{dt} \cdot \frac{dq}{dt} = a a' \sin p \sin q;$$

but we have found

$$\frac{dp}{dt} \cdot \frac{dq}{dt} = -e^2 \sin p \sin q,$$

therefore $a a' = -e^2$, and one of the two equations

$$\frac{dp}{dt} = a \sin q, \quad \frac{dq}{dt} = a' \sin p,$$

III. Integral Calculus.

is an immediate deduction from the other. Let us substitute, now, in these for p and q , $\frac{dp}{dt}$ and $\frac{dq}{dt}$ their values in terms of ϕ and θ , we shall find

$$\begin{aligned}\sqrt{1 - e^2 \sin^2 \phi} - \sqrt{1 - e^2 \sin^2 \theta} &= a \sin(\phi - \theta), \\ \sqrt{1 - e^2 \sin^2 \phi} + \sqrt{1 - e^2 \sin^2 \theta} &= a' \sin(\phi + \theta),\end{aligned}$$

which are the integrals of the proposed equation put under two different forms. We may give it still a simpler form.

For that purpose we shall eliminate dt between the values of $\frac{dp}{dt}$ and $\frac{dq}{dt}$; we find $a \sin q \, dq = a' \sin p \, dp$, and

in integrating $a \cos q = a' \cos p + a''$.

To reduce to one the three constants a, a', a'' , let μ be the value of ϕ corresponding to $\theta = 0$; the two forms of the integral we have first obtained, will give, in that supposition,

$$a = \frac{-1 + \sqrt{1 - e^2 \sin^2 \mu}}{\sin \mu}, \quad a' = \frac{1 + \sqrt{1 - e^2 \sin^2 \mu}}{\sin \mu};$$

these values being substituted in the equation $a \cos q = a' \cos p + a''$, which in the hypothesis of $\theta = 0$, and

$\phi = \mu$, becomes $(a - a') \cos \mu = a''$, gives $a'' = -\frac{2 \cos \mu}{\sin \mu}$. This value, those of a and a' , and of p and q in

terms of ϕ and θ , being substituted in the equation $a \cos q = a' \cos p + a''$, will lead to the integral

$$\cos(\phi - \theta) \{ -1 + \sqrt{1 - e^2 \sin^2 \mu} \} = \cos(\phi + \theta) \{ 1 + \sqrt{1 - e^2 \sin^2 \mu} \} - 2 \cos \mu,$$

which will be successively transformed into

$$\cos(\phi - \theta) + \cos(\phi + \theta) + \{ \cos(\phi + \theta) - \cos(\phi - \theta) \} \sqrt{1 - e^2 \sin^2 \mu} = 2 \cos \mu,$$

or

$$\cos \phi \cos \theta - \sin \phi \sin \theta \sqrt{1 - e^2 \sin^2 \mu} = \cos \mu.$$

Now, if we designate by $f(\phi)$ the transcendant $\int \frac{d\phi}{\sqrt{1 - e^2 \sin^2 \phi}}$, and by $f(\theta)$ the value of $\int \frac{d\theta}{\sqrt{1 - e^2 \sin^2 \theta}}$, the proposed differential equation will immediately give $f(\phi) + f(\theta) = \beta$, and since when $\theta = 0$, $\phi = \mu$, we have $\beta = f(\mu)$, and, therefore, when

$$\cos \phi \cos \theta - \sin \phi \sin \theta \sqrt{1 - e^2 \sin^2 \mu} = \cos \mu,$$

we shall have

$$f(\phi) + f(\theta) = f(\mu).$$

If the proposed differential equation had been

$$\frac{d\phi}{\sqrt{1 - e^2 \sin^2 \phi}} - \frac{d\theta}{\sqrt{1 - e^2 \sin^2 \theta}} = 0,$$

by a similar process, we would have found that when

$$\cos \phi \cos \theta + \sin \phi \sin \theta \sqrt{1 - e^2 \sin^2 \mu} = \cos \mu,$$

we shall have

$$f(\phi) - f(\theta) = f(\mu).$$

It is from the combination of the equations we have just found that Legendre has deduced the properties of the function designated here by $f(\phi)$, to which we have alluded before.

(123.) When the left side of a differential equation $M dx + N dy = 0$, does not satisfy the criterion of integrability, that is, when $\frac{dM}{dy}$ does not equal $\frac{dN}{dx}$, it is possible, in some cases, to discover a factor such, that the left side of the equation, after having been multiplied by it, becomes the immediate differential of a function of two variables.

It is easy to see, that if we admit that every differential equation has an integral, such a factor must always exist. For if $f(x, y) = c$ be the integral of $M dx + N dy = 0$, c being the arbitrary constant, and if $P dx + Q dy = 0$, is the immediate differential of $f(x, y) = c$, the value of $\frac{dy}{dx} = -\frac{P}{Q}$ deduced from it,

must satisfy the equation $M dx + N dy = 0$; therefore $\frac{P}{Q}$ must be equal to $\frac{M}{N}$, and there is, consequently, a

certain factor by which the two terms of the fraction $\frac{M}{N}$, being multiplied, will become equal to $\frac{P}{Q}$, or in other words, a quantity by which the differential equation $M dx + N dy = 0$, being multiplied, will be transformed into the immediate differential $P dx + Q dy = 0$.

Let z be the factor by which it is necessary to multiply $M dx + N dy = 0$, to render the left side of it the immediate differential of a function of two variables. Then $Mz dx + Nz dy$ will satisfy the condition

$$\frac{dMz}{dy} = \frac{dNz}{dx}, \text{ or in developing this equation,}$$

Integral
Calculus.

or

$$M \frac{dz}{dy} + z \frac{dM}{dy} = N \frac{dz}{dx} + z \frac{dN}{dx},$$

$$M \frac{dz}{dy} - N \frac{dz}{dx} + \left(\frac{dM}{dy} - \frac{dN}{dx} \right) z = 0.$$

If in all the cases the value of z could be found by means of this last equation, then every differential equation of the form $M dx + N dy = 0$, could be integrated; or, at least, the difficulty would be reduced to the integration of a function of one variable. But, in general, the difficulty of determining the value of z , is of a higher degree than the integration of the proposed equation, since the equation from which it is to be obtained contains the partial differential coefficients of z with respect to two variables x and y .

The cases in which general rules may be given to find the value of the factor z are precisely those in which the integral of $M dx + N dy = 0$ may be obtained by some of the preceding rules. We shall not, in consequence, enter here into any details of the investigation of this factor. We shall only observe, that when we know a value of the factor z , we may easily deduce from it an infinite number of other factors which will satisfy the same condition.

Let u be the function of x and y , of which $z M dx + z N dy$ is the differential, then

$$du = z M dx + z N dy;$$

and if we multiply both sides of this equation by any function of u , which we shall designate by $\phi(u)$, we shall have

$$\phi u du = z \phi(u) M dx + z \phi(u) N dy,$$

which is an identical equation, the left side of which is obviously an exact differential; and, consequently, we infer that z multiplied by any function of u will be a factor by which $M dx + N dy$ being multiplied will become an immediate differential.

The preceding remark may be used to find the value of the factor when the proposed differential equation may be decomposed into two parts, for each of which a factor can be found. Let

$$p dx + q dy + p' dx + q' dy = 0$$

be the proposed equation, and let us suppose that factors which will make the two parts $p dx + q dy$ and $p' dx + q' dy$, separately, immediate differentials are known; and let them be represented by z and z' , so that $z p dx + z q dy = du$, and $z' p' dx + z' q' dy = du'$; hence $z \phi(u)$ and $z' \phi'(u')$, $\phi(u)$ and $\phi'(u')$ designating any two functions of u and u' , will include all the factors relative to the two parts $p dx + q dy$, and $p' dx + q' dy$; if, therefore, it is possible to determine the forms of the functions ϕ and ϕ' , in such a manner that $z \phi(u) = z' \phi'(u')$, we shall have one of the factors which will render $p dx + q dy + p' dx + q' dy$ an immediate differential.

Let us take, for example, the equation

$$a y dx + \beta x dy = x^m y^n (\gamma y dx + \delta x dy).$$

It is easily seen that the left side becomes an immediate differential when it is multiplied by $\frac{1}{xy}$, and the right side when multiplied by $\frac{1}{x^{m+1} y^{n+1}}$. In this case, therefore, $z = \frac{1}{xy}$ and $z' = \frac{1}{x^{m+1} y^{n+1}}$; and since when the two sides of the equation are multiplied by these factors they become

$$\frac{a dx}{x} + \frac{\beta dy}{y}, \quad \frac{\gamma dx}{x} + \frac{\delta dy}{y},$$

which are respectively equal to

$$d \cdot (a l x + \beta l y) = d \cdot l(x^a y^\beta) \text{ and } d(\gamma l x + \delta l y) = d l(x^\gamma y^\delta),$$

we shall have

$$u = l(x^a y^\beta) \text{ and } u' = l(x^\gamma y^\delta);$$

therefore

$$\frac{1}{xy} \phi(x^a y^\beta) \text{ and } \frac{1}{x^{m+1} y^{n+1}} \phi'(x^\gamma y^\delta)$$

will be the general forms of the factors of the two sides of the equation. Here there is no difficulty in making those two expressions equal; for if we suppose

$$\phi(x^a y^\beta) = x^{ka} y^{k\beta}, \text{ and } \phi'(x^\gamma y^\delta) = x^{k'\gamma} y^{k'\delta},$$

they become respectively

$$x^{ka-1} y^{k\beta-1}, \text{ and } x^{k'\gamma-m-1} y^{k'\delta-n-1};$$

they will, therefore, be equal, if

$$ka - 1 = k'\gamma - m - 1, \text{ and } k\beta - 1 = k'\delta - n - 1,$$

from which equations we derive the values

$$k = \frac{\gamma n - \delta m}{a\delta - \beta\gamma}, \quad k' = \frac{a n - \beta m}{a\delta - \beta\gamma}.$$

The required factor is, consequently,

$$\frac{x^{\frac{(\gamma n - \delta m)a}{a\delta - \beta\gamma} - 1}}{y^{\frac{(\gamma n - \delta m)\beta}{a\delta - \beta\gamma} - 1}};$$

and the proposed equation, being multiplied by that factor and integrated, gives

Integral
Calculus.

$$\frac{a\delta - \beta\gamma}{\gamma n - \delta m} x^{\frac{(\gamma n - \delta m)\alpha}{\alpha\delta - \beta\gamma}} y^{\frac{(\gamma n - \delta m)\beta}{\alpha\delta - \beta\gamma}} = \frac{a\delta - \beta\gamma}{a n - \beta m} x^{\frac{(\alpha n - \beta m)\alpha}{\alpha\delta - \beta\gamma}} y^{\frac{(\alpha n - \beta m)\beta}{\alpha\delta - \beta\gamma}} + c.$$

If $\gamma n = \delta m$, the factor is reduced to $x^{-1} y^{-1} = \frac{1}{xy}$, and in observing that $\delta = \frac{\gamma n}{m}$, the equation becomes, after the multiplication,

$$\frac{a dx}{x} + \frac{\phi dy}{y} = \frac{\gamma}{m} x^{m-1} y^{n-1} (m dx + n dy),$$

the integral of which is

$$l(x^m y^n) = \frac{\gamma x^m y^n}{m} + c.$$

If $a\delta = \beta\gamma$ the values of k and k' become equal to infinity; but in that case the equation is reduced to

$$a y dx + \beta x dy = \frac{\gamma}{a} x^m y^n (a y dx + \beta x dy),$$

or

$$(a y dx + \beta x dy) \left(1 - \frac{\gamma}{a} x^m y^n\right) = 0,$$

which gives two solutions, $x^m y^n = c$ and $1 - \frac{\gamma}{a} x^m y^n = 0$. The first is the true integral, since it contains an arbitrary constant; the second is a particular case of it, when $\beta m = a n$. We shall see in the sequel what is the meaning of such integrals.

(124.) In order to be able to try the preceding method in several cases, where one or both the parts into which the proposed differential equation has been decomposed are homogeneous, we shall investigate the value of the factor z , which makes the differential expression $M dx + N dy$ an exact differential, when M and N are homogeneous functions. In that supposition if we assume $y = ux$, and substitute, M and N will become divisible by x^m , m being the common degree of these quantities, so that the values of M and N may be represented as we have done before by $x^m \phi(u)$ and $x^m \psi(u)$, and we shall have

$$M dx + N dy = (\phi(u) + u \psi(u)) x^m dx + \psi(u) \cdot x^{m+1} du.$$

The right side of this equation becomes clearly an exact differential, if we multiply it by

$$\frac{1}{\{\phi(u) + u \psi(u)\} x^{m+1}},$$

since it then becomes

$$\frac{dx}{x} + \frac{\psi(u) du}{\{\phi(u) + u \psi(u)\}},$$

therefore

$$\frac{M dx + N dy}{\{\phi(u) + u \psi(u)\} x^{m+1}} = \frac{dx}{x} + \frac{\psi(u) du}{\{\phi(u) + u \psi(u)\}} = d \cdot F(x, u),$$

or putting again for u its value $\frac{y}{x}$, and for $\phi(u)$ and $\psi(u)$ their values $\frac{M}{x^m}$, and $\frac{N}{x^m}$, we get

$$\frac{M dx + N dy}{M x + N y} = d F\left(x, \frac{y}{x}\right) = d \cdot f(x, y).$$

Hence it appears that the factor which will render an homogeneous differential expression $M dx + N dy$ an immediate differential is $\frac{1}{M x + N y}$. This factor becomes infinite when $M x + N y = 0$, but then $N = -\frac{M x}{y}$ and $M dx + N dy = \frac{M}{y} (y dx - x dy)$, which becomes the exact differential of $\frac{y}{x}$, when multiplied by $\frac{1}{M y}$.

Let, for example, the equation be

$$y dy - x dx + \frac{b(y dx - x dy)}{x^6} = 0.$$

The left side is separated into two parts, each of which is homogeneous. The factor which will render the first part $y dy - x dx$ an exact differential, is, according to what precedes, $\frac{1}{y^2 - x^2}$; that corresponding to the second part is $-x^4$. After the multiplications, the two parts become respectively the differentials of $\frac{1}{2} \sqrt{y^2 - x^2}$, and of $\frac{y}{x}$; hence the general forms of the factors will be $\phi(y^2 - x^2)$, and $-x^4 \psi\left(\frac{y}{x}\right)$, ϕ and ψ designating any two functions. It remains now to examine if we can find the forms of these functions which

Integral
Calculus.

will make

$$\phi(y^2 - x^2) = -x^4 \psi\left(\frac{y}{x}\right)$$

This will not be very difficult, if we consider that $\phi(y^2 - x^2) = \phi\left\{x^2\left(\frac{y^2}{x^2} - 1\right)\right\}$, which may be supposed equal to $x^4\left(\frac{y^2}{x^2} - 1\right)^2$, and consequently that by taking $\psi\left(\frac{y}{x}\right) = \left(\frac{y^2}{x^2} - 1\right)^2$, we shall have

$$\phi(y^2 - x^2) = x^4 \psi\left(\frac{y}{x}\right).$$

The factor, which will make the left side of the proposed differential equation an immediate differential, is therefore $x^4\left(\frac{y^2}{x^2} - 1\right)^2$, or $(y^2 - x^2)^2$. Multiplying by this quantity, and integrating, we get

$$\frac{(y^2 - x^2)^3}{6} - \frac{b y^5}{5 x^5} + \frac{2 b y^3}{3 x^3} - \frac{b y}{x} = c.$$

(125.) Instead of proposing to determine, *à priori*, the value of the factor for a given differential equation, the problem may be reversed; and, assuming a certain form of the differential equation, and of the factor by which it is to be multiplied, in one or both of which there are undeterminate quantities, it may be proposed to find the relations which ought to subsist between the undeterminate quantities, in order that the assumed factor should render the assumed equation an immediate differential.

Let it be required, for instance, to determine the relations between the functions p , q , m , and N of x , in order that the equation $p y dx + (y + q) dy = 0$, when multiplied by the factor $\frac{1}{y^3 + m y^2 + n y}$, may satisfy the criterion of integrability. The equation given by this condition is

$$\frac{d \frac{p y}{y^3 + m y^2 + n y}}{d y} = \frac{d \frac{y + q}{y^3 + m y^2 + n y}}{d x},$$

which, being developed, gives

$$-2 p y^3 - p m y^2 = (y^3 + m y^2 + n y) \frac{d q}{d x} - (y + q) \left(y^2 \frac{d m}{d x} + y \frac{d n}{d x} \right),$$

$$\text{or} \quad \left(2 p + \frac{d q}{d x} - \frac{d m}{d x} \right) y^3 + \left(p m + m \frac{d q}{d x} - q \frac{d m}{d x} - \frac{d n}{d x} \right) y^2 + \left(n \frac{d q}{d x} - q \frac{d n}{d x} \right) y = 0;$$

and since the equation must be identical, we must have

$$2 p + \frac{d q}{d x} - \frac{d m}{d x} = 0, \quad p m + m \frac{d q}{d x} - q \frac{d m}{d x} - \frac{d n}{d x} = 0, \quad n \frac{d q}{d x} - q \frac{d n}{d x} = 0,$$

three equations, by means of which we may determine the values of three of the four quantities p , q , m , and n .

The last equation may be put under the form $\frac{d n}{n} = \frac{d q}{q}$, and gives by integration $n = a q$, a being an arbitrary constant; substituting this value in the two other equations they become

$$2 p dx + dq - dm = 0, \quad p m dx + m dq - q dm - a dq = 0,$$

and in eliminating p

$$(2 q - m) dm + (2 a - m) dq = 0.$$

If we consider m and q as the two variables of this equation, we may easily find the factor which will make the left side an immediate differential. Let us assume that it contains only m , and let it be represented by $\phi(m)$, then we must have

$$d \frac{\phi(m) \cdot (2 q - m)}{d q} = d \frac{\phi(m) \cdot (2 a - m)}{d m}, \text{ or } 2 \phi(m) = \frac{d \phi(m)}{d m} (2 a - m) - \phi(m),$$

and successively

$$\frac{d \phi(m)}{3 \phi(m)} = \frac{d m}{2 a - m}, \quad \frac{1}{3} \int \phi(m) = \int \frac{1}{(2 a - m)}, \quad \text{and } \phi(m) = \frac{1}{(2 a - m)^3}.$$

Having discovered this factor, we may now proceed to the integration of

$$(2 q - m) q m + (2 a - m) dq = 0.$$

The multiplication will transform the left side into $\frac{2 q - m}{(2 a - m)^3} dm + \frac{dq}{(2 a - m)^2}$; integrating this by the rules relative to functions of two variables, we get after reduction

$$q = m - a + b (2 a - m)^2;$$

but since $2 p dx + dq - dr = 0$, the preceding value of q will give

Integral
Calculus.

$$p = b(2a - m) \frac{dm}{dx};$$

taking, therefore, for m any function of x , we shall get

$$p = b(2a - m) \frac{dm}{dx}, \quad q = m - a + b(2a - m)^2,$$

and

$$n = a(m - a) + ab(2a - m)^2;$$

and the proposed equation will be changed into

$$by(2a - m)dm + (m - a + b(2a - m)^2 + y)dy = 0,$$

and will become an immediate differential by means of the factor

$$\frac{1}{y^3 + my^2 + (m - a + b(2a - m)^2)ay}$$

m being any function of x .

These kind of investigations, which were first undertaken by Euler, however, frequently involve differential equations which cannot be integrated by any known method; and it cannot be said that the cases in which they are successful, are of very great importance or extent.

In order to ensure this method all the success of which it is capable, it would require a very complete classification of the forms of differential equations of the first order, as well as a knowledge of the forms of the multipliers which are suited to each class. The immense extent, however, of this inquiry, and the great difficulties which are met with, even in the simplest cases, seems to preclude all hopes of its proving of much service in the general integration of differential equations of the first order.

(126.) We have now examined all the general cases in which differential equations of the form $Mdx + Ndy = 0$ can be integrated; and we have pointed out the means of determining in particular cases the value of the factor, which will make $Mdx + Ndy$ an immediate differential, in trying various forms of this factor with undeterminate coefficients and functions.

In number (123.) it has already been stated that the integration of differential equations of the first order, in which the differential coefficient $\frac{dy}{dx}$ enters in a degree higher than the first can be, in general reduced to the integration of equations of the form $Mdx + Ndy = 0$. Let us take a simple example of this case, which will give rise to an important remark.

Let $dy^2 - a^2 dx^2 = 0$ be the proposed equation. Decomposed into factors according to (123.), it becomes

$$\left(\frac{dy}{dx} - a\right)\left(\frac{dy}{dx} + a\right) = 0;$$

and it will be satisfied by the integral of either of the equations formed by rendering these factors equal to nothing; that is, by

$$y - ax - c = 0, \text{ or } y + ax - c' = 0.$$

It will also be satisfied by the product of these two equations, or

$$(y - ax - c)(y + ax - c') = 0.$$

This last integral appears more general than the other two, because it contains two arbitrary constants instead of one; but, it may be observed, that when an equation between x and y can be put under the form

$$X_1 \cdot X_2 \cdot X_3 \dots = 0,$$

X_1, X_2 , &c. being functions of x and y , each of which contains a constant c_1, c_2, c_3 , &c. not found in the others, all these constants can always be eliminated between the proposed equation and its differential of the first order. Hence, in the integral of a differential equation of the form

$$\left(\frac{dy}{dx} - p_1\right)\left(\frac{dy}{dx} - p_2\right) \&c. = 0,$$

obtained by multiplying together the integrals X_1, X_2 , &c. of each factor, the number of arbitrary constants it contains cannot be said to indicate a greater degree of generality; and we may, in general, assume any relation we please between these constants; we may, for instance, assume them to be all equal to each other. In that last supposition, the integral in the example we have chosen becomes

$$(y - c)^2 - a^2 x^2 = 0.$$

(127.) The method we have used in the last example, were it not for the difficulty of decomposing the proposed differential equation into factors, would be sufficient to make the integration depend upon that of equations of the form $Mdx + Ndy = 0$. But frequently the decomposition cannot be effected, and it is always best to avoid it when there is any possibility.

This can be done in several cases:

1st. When in the proposed equation

$$\frac{dy^n}{dx^n} + P \frac{dy^{n-1}}{dx^{n-1}} + Q \frac{dy^{n-2}}{dx^{n-2}} + \&c. = 0. \dots (1),$$

Integral
Calculus.

all the coefficients $P, Q, \&c.$ are constant quantities; for if we assume $dy = m dx$, we shall have to determine the value of m the equation Part III.

$$m^n + P m^{n-1} + Q m^{n-2} + \&c. = 0;$$

consequently m is a constant quantity; and since $dy = m dx$, we get by integration $y = mx + c$; eliminating m between this equation and the preceding, we shall have for the integral of the proposed equation

$$\left(\frac{y-c}{x}\right)^n + P \left(\frac{y-c}{x}\right)^{n-1} + Q \left(\frac{y-c}{x}\right)^{n-2} + \&c. = 0.$$

2dly. The resolution of the equation (1) may also be avoided when the coefficients $P, Q, \&c.$ contain only x , and that the value of x may be derived from it in function of $\frac{dy}{dx}$.

In that case make $\frac{dy}{dx} = p$, then by the equation we get $x = \phi(p)$. But $dy = p dx$, and consequently

$$y = px - \int x dp = px - \int \phi(p) dp;$$

eliminating p between this equation and the proposed, we shall obtain the required integral.

Example. Let the proposed equation be $\frac{dy^2}{dx^2} + \frac{x-1}{x} = 0$; making $\frac{dy}{dx} = p$, we get $x = \frac{1}{1+p^2}$, and therefore $y = px - \int \frac{p dp}{1+p^2} = px - \tan^{-1} p + c$; eliminating p , we find for the required integral

$$y = \sqrt{x^2 - x} - \tan^{-1} \sqrt{\frac{x-1}{x}} + c.$$

When the coefficients $P, Q, \&c.$ instead of x contain y , we must assume $\frac{dx}{dy} = p$, from which $x = py - \int y dp$, and then eliminate p as before.

Sometimes, instead of finding the value of x in terms of p , it is simpler to express both quantities in terms of another variable, the final elimination of which leads to the required integral.

Example. Let the equation be $x^3 + \frac{dy^3}{dx^3} = ax \frac{dy}{dx}$, or $x^3 + p^3 = xpx$; the values of x in terms of p , or of p in terms of x , would be rather complicated. Assume $p = ux$, then $x + u^3 x = au$, and hence

$$x = \frac{au}{1+u^3}, \quad p = \frac{au^2}{1+u^3};$$

substituting for p and for dx their values in the expression $y = \int p dx$, we find

$$y = a^2 \int \frac{u^2 du (1-2u^3)}{(1+u^3)^3} = \frac{1}{6} a^2 \frac{2u^3-1}{(1+u^3)^2} + \frac{1}{3} a^2 \frac{1}{1+u^3} + c,$$

and by eliminating u between this value of y and the equation $x = \frac{au}{1+u^3}$, we shall obtain the integral.

3dly. If in equation (1.) $P, Q, \&c.$ be homogeneous functions, we shall suppose $y = ux$, then x will disappear and the equation will contain only u and $\frac{dy}{dx} = p$. But since

$$y = ux, \quad dy = u dx + x du, \quad \text{that is } p dx = u dx + x du, \quad \text{or } \frac{dx}{x} = \frac{du}{p-u},$$

which gives

$$lx = \int \frac{du}{p-u}, \quad \text{or } x = e^{\int \frac{du}{p-u}} \quad \text{and } y = u e^{\int \frac{du}{p-u}};$$

and substituting in each of these, the value of u in terms of p , or of p in terms of u , and eliminating, we shall get the integral.

Example. Let the equation be $y dx - x dy = x \sqrt{dx^2 + dy^2}$, or $y - px = x \sqrt{1+p^2}$, the supposition of $y = ux$ will give $u = p + \sqrt{1+p^2}$; but $\frac{dx}{x} = \frac{du}{p-u}$, or integrating

$$lx = \int \frac{du - dp}{p-u} + \int \frac{dp}{p-u} = -l(p-u) + \int \frac{dp}{p-u};$$

substituting for u its value in p , we find

$$lx = -l \sqrt{1+p^2} + \int \frac{-dp}{\sqrt{1+p^2}} = -l \sqrt{1+p^2} - \log \{p + \sqrt{1+p^2}\} + lc,$$

and consequently

$$x = \frac{e^c}{\sqrt{1+p^2} \{p + \sqrt{1+p^2}\}} = \frac{-e^c}{\sqrt{1+p^2}} \{p - \sqrt{1+p^2}\}, \quad \text{and } y = ux = \frac{e^c}{\sqrt{1+p^2}};$$

Integral
Calculus.

Part III.

 eliminating p between the values of x and y , we get

$$x^2 + y^2 - 2cx = 0$$

for the integral.

(128.) There is still another case, pointed out by Clairaut, which is not of unfrequent occurrence, and which may be integrated without resolving the equation with respect to the differential coefficient. It is when the

 proposed differential equation is of the form $y = F(x, p)$, where $p = \frac{dy}{dx}$. We shall have by differentiating,

$$dy = R dx + S dp, \text{ or since } p dx = dy, p dx = R dx + S dp, \text{ or } (R - p) dx = S dp.$$

 If we could integrate this last equation, by eliminating p between the integral and the proposed equation, we would obtain the required relation between x , y and an arbitrary constant.

 If $y = px + P$ be the proposed equation, P being any function of p alone, this method succeeds. For if we differentiate we get $dy = p dx + d p \left(x + \frac{dP}{dp} \right)$, or simply $d p \left(x + \frac{dP}{dp} \right) = 0$, since $dy = p dx$. This

 last equation may be decomposed into two others, $dp = 0$ and $x + \frac{dP}{dp} = 0$. Eliminating p between the last

 and the equation $y = px + P$, we shall have an equation between x and y which will satisfy the proposed differential equation, but which cannot be considered as the complete integral, since it will not contain an arbitrary constant; it will belong to the class of integral equations which are designated under the name of *particular integrals*; the consideration of these integrals is of great importance, and we shall in the proper place return to that subject. The other equation $dp = 0$ gives $p = c$, or $dy = c dx$, or $y = cx + c'$, with two constants c and c' ; but these constants are not independent of each other; for in making in the proposed equation $p = c$, we get $y = cx + C$, c being what P becomes when in it c is written instead of p ; hence $c' = C$. We shall, therefore, obtain the complete integral of $y = px + P$, in substituting for p an arbitrary constant c .

 Example. Let the proposed equation be $y dx - x dy = a \sqrt{(dx^2 + dy^2)}$. It may be written

$$y = x \frac{dy}{dx} + a \sqrt{\left(1 + \frac{dy^2}{dx^2}\right)} = px + a \sqrt{1 + p^2},$$

and therefore the general or complete integral will be

$$y = cx + a \sqrt{1 + c^2}.$$

 The same method will still be successful when the proposed equation is of the form $y = Px + P'$, P and P' being functions of p alone. If we differentiate, and put for dy its value $p dx$, we get

$$(P - p) dx + \left(x \frac{dP}{dp} + \frac{dP'}{dp} \right) dp = 0.$$

 This is a linear equation of the first order, and may be integrated by the method used in (116.); it will be sufficient to eliminate p between the result and the proposed equation $y = Px + P'$ to get the required integral.

 Example. Let the equation be $y = nx \frac{dy}{dx} + a \sqrt{\left(1 + \frac{dy^2}{dx^2}\right)}$, or $y = np x + a \sqrt{1 + p^2}$.

 Differentiating and putting $p dx$ for dy , we have

$$(n - 1) p dx + \left(nx + \frac{dp}{\sqrt{1 + p^2}} \right) dp = 0, \text{ or } dx + \frac{n}{(n - 1)p} x dp = - \frac{a dp}{(n - 1) \sqrt{1 + p^2}},$$

integrating we get

$$p^{\frac{n}{n-1}} x = - \frac{a}{n-1} \int \frac{p^{\frac{n}{n-1}} dp}{\sqrt{1 + p^2}},$$

 and the result of the elimination of p between this and the proposed equation will be the integral.

(129.) Besides the different general cases we have examined, there are many in which the integration may be effected by means of some transformations, or substitutions, for which no general rule can be given. We shall take two examples of these cases which do not come under any of the rules given in the preceding paragraphs.

 Example 1. Let $\frac{x dy - y dx}{\sqrt{dx^2 + dy^2}} = \sqrt{(x^2 + y^2 - a^2)}$ be the proposed equation. Assume $x = uz$ and $y = u$
 $\sqrt{1 - z^2}$, then $dx = u dz + z du$, $dy = - \frac{uz dz}{\sqrt{1 - z^2}} + du \cdot \sqrt{1 - z^2}$, the equation will become

$$\frac{-u^2 dz}{\sqrt{\{u^2 dz^2 + (1 - z^2) du^2\}}} = \sqrt{(u^2 - a^2)};$$

or in raising both sides to the square, and reducing, we find

$$\frac{dz}{\sqrt{1 - z^2}} = \frac{du \sqrt{u^2 - a^2}}{du},$$

where the variables are separated, and which being integrated gives

$$\sin^{-1} z = -\sin^{-1} \frac{\sqrt{(u^2 - a^2)}}{u} + \frac{\sqrt{(u^2 - a^2)}}{a} + C;$$

and substituting for z and u their values in x and y , which are respectively

$$z = \frac{x}{\sqrt{(x^2 + y^2)}}, \quad u = \sqrt{(x^2 + y^2)},$$

we shall find

$$\sin^{-1} \frac{x}{\sqrt{(x^2 + y^2)}} + \sin^{-1} \frac{\sqrt{(x^2 + y^2 - a^2)}}{\sqrt{(x^2 + y^2)}} = \frac{\sqrt{(x^2 + y^2 - a^2)}}{a} +$$

Example 2. Let the equation be $\frac{dy^a}{dx^k} = Ax^a + By^b$. Assume $x^a u^b = y^b$, we shall get in substituting for y and dy their values

$$x^{\frac{a}{b}} du + \frac{a}{\beta} x^{\frac{a-\beta}{b}} u dx = x^{\frac{a}{k}} dx (A + B u^{\frac{1}{k}}),$$

and if k is supposed equal to $\frac{a\beta}{a-\beta}$ we shall have

$$\beta x^{\frac{a}{b} - \frac{a}{k}} du + a u dx = \beta dx (A + B u^{\frac{1}{k}}),$$

and consequently

$$\frac{dx}{x^{\frac{a}{b} - \frac{a}{k}}} = \frac{\beta du}{\beta (A + B u^{\frac{1}{k}}) - a u},$$

where the variables are separated.

(130.) The difficulty of integration is much greater for differential equations of the second, third, or higher orders; that is, of equations in which are involved the differential coefficients of the second or third or higher orders, than for those of the first order.

The general process consists in deducing from the proposed equation another differential equation of an order less by one; from this another of an order less by two, and so on in succession till an equation between x and y , and without differential coefficients, be obtained. The first of this series of equations is called a *first integral* of the proposed; the second, a *second integral* of the proposed, &c.

(131.) It is manifest, from what has already been stated with respect to the elimination of constants between a proposed equation and its successive differentials, that a differential equation of the n^{th} order may be obtained with n constants less than the primitive equation. Hence the integral of a differential equation of the n^{th} order, ought to be as general as possible, to contain n arbitrary constants. It also results from the manner in which differential equations may be supposed to arise from the elimination of constants between the primitive equation and its differentials, that if the primitive equation contains n constants, there may be n distinct differential equations of the order $n - 1$, each containing only one of the n constants; every one of these equations will be a first integral of the differential equation of the n^{th} order; and therefore to a differential equation of the n^{th} order correspond n first integrals, each with a constant. To obtain the general integral of the proposed equation with n arbitrary constants, when we shall be able to find these n first integrals, it will be sufficient to eliminate between them the $n - 1$ differential coefficients which they contain.

Let, for instance, $y^2 = m(a^2 - x^2)$ be a primitive equation, with two constants m and a . A first differentiation gives $y dy = -mx dx$, where the constant a has disappeared; if we differentiate again, and eliminate m , we find for the differential equation of the second order, without constants,

$$y \frac{dy}{dx} - x \frac{dy^2}{dx^2} - xy \frac{d^2 y}{dx^2} = 0.$$

We can arrive at the same equation in a different manner; for, eliminating m between the proposed equation and the differential of the first order, we shall have

$$xy dx + dy(a^2 - x^2) = 0,$$

and then it will be sufficient to differentiate again, and eliminate a .

In this case, the two equations

$$y dy = -mx dx, \quad xy dx + dy(a^2 - x^2) = 0,$$

are the first integrals of

$$y \frac{dy}{dx} - x \frac{dy^2}{dx^2} - xy \frac{d^2 y}{dx^2} = 0,$$

and by eliminating $\frac{dy}{dx}$ between them, we find the primitive equation

$$y^2 = m(a^2 - x^2).$$

(132.) We shall now examine successively the cases in which the integrations of differential equations of higher orders may be effected.

Integral
Calculus.

Part III.

We need not consider the case in which the equation is of the form $\frac{d^n y}{dx^n} = X$, X being a function of x ; it is

evident that by n successive integrations we shall find the value of y .

It will always be easy to reduce to this case the integration of an equation containing only two successive differential coefficients of y and constants. Let us suppose, for instance, that the proposed equation contains only $\frac{d^3 y}{dx^3}$ and $\frac{d^2 y}{dx^2}$, if we assume $\frac{d^2 y}{dx^2} = q$ we shall have $\frac{d^3 y}{dx^3} = \frac{dq}{dx}$, and the equation will give $\frac{dq}{dx} = Q$,

Q being a function of q ; hence $dx = \frac{dq}{Q}$ and $x = \int \frac{dq}{Q} + c$; but since $\frac{d^2 y}{dx^2} = q$, we have

$$\frac{dy}{dx} = \int q dx + c' = \int \frac{q dq}{Q} + c', \text{ and } y = \int dx \left\{ \int \frac{q dq}{Q} + c' \right\} + c''.$$

The required integral will therefore be the result of the elimination of q between the two equations

$$x = \int \frac{dq}{Q} + c, \text{ and } y = \int dx \left\{ \int \frac{q dq}{Q} + c' \right\} + c'';$$

it will be the general integral, since it will contain three arbitrary constants c, c', c'' .

Example 1. Let $d^2 y = dx \sqrt{(dy^2 + dx^2)}$ be the proposed equation, and let $\frac{dy}{dx} = p$, then $\frac{d^2 y}{dx^2} = \frac{dp}{dx}$, and the equation becomes $\frac{dp}{dx} = \sqrt{(1 + p^2)}$, or $dx = \frac{dp}{\sqrt{(1 + p^2)}}$; hence $dy = p dx = \frac{p dp}{\sqrt{(1 + p^2)}}$; integrating we find

$$x = l(p + \sqrt{(1 + p^2)}) + c, \text{ and } y = \sqrt{(1 + p^2)} + c'.$$

The elimination of p from these equations will give for the required integral

$$x = l[c \{ y - c' + \sqrt{(y - c')^2 - 1} \}].$$

Example 2. Let the proposed equation be

$$a d^2 y d^3 y = dx^2 \sqrt{(dx^4 + d^2 y^2)}.$$

Make $\frac{d^2 y}{dx^2} = q$, and $\frac{d^3 y}{dx^3} = \frac{dq}{dx} = r$, the equation will become $a q r = \sqrt{(1 + q^2)}$, or $a r = \frac{\sqrt{(1 + q^2)}}{q}$, or again $\frac{a dq}{dx} = \frac{\sqrt{(1 + q^2)}}{q}$ and $dx = \frac{a q dq}{\sqrt{(1 + q^2)}}$ hence $x = a \int \frac{q dq}{\sqrt{(1 + q^2)}} + c$. Now

$$p \frac{dy}{dx} = \int q dx = \int \frac{a q^2 dq}{\sqrt{(1 + q^2)}} = \frac{a}{2} \sqrt{(1 + q^2)} - \frac{a}{2} l \{ q + \sqrt{(1 + q^2)} \} + c';$$

$$\text{but } dy = p dx = \frac{a^2 q^2 dq}{2} - \frac{a^2 q dq}{2 \sqrt{(1 + q^2)}} l \{ q + \sqrt{(1 + q^2)} \} + \frac{a c' q dq}{\sqrt{(1 + q^2)}},$$

$$\text{and consequently, } y = \frac{a^2 q^3}{6} - \frac{a^2}{2} \sqrt{(1 + q^2)} l \{ q + \sqrt{(1 + q^2)} \} + \frac{a^2}{2} q + a c' \sqrt{(1 + q^2)} + c''.$$

The elimination of q between the values of x and y will give the required relation between these two variables.

(133.) Let us next consider the case where the differential equation contains only two differential coefficients, the order of one of which is greater by two than the order of the other.

Let us suppose, for instance, that the differential equation contains only $\frac{d^4 y}{dx^4}$ and $\frac{d^2 y}{dx^2}$, and that the value of the first can be expressed in terms of the second.

Let $\frac{d^2 y}{dx^2} = q$, then $\frac{d^3 y}{dx^3} = \frac{dq}{dx}$ and $\frac{d^4 y}{dx^4} = \frac{d^2 q}{dx^2}$. The proposed equation will therefore assume the form $\frac{d^2 q}{dx^2} = Q$, when Q designates a function of q . If we multiply both sides of this equation by dq , we get

$$\frac{dq}{dx} \cdot \frac{d^2 q}{dx^2} = Q dq, \text{ and integrating } \frac{1}{2} \frac{d^3 q}{dx^3} = \int Q dq + c, \text{ or } \frac{d^3 q}{dx^3} = \sqrt{(2 \int Q dq + c)};$$

$$\text{or again, } dx = \frac{dq}{\sqrt{(2 \int Q dq + c)}}, \text{ and by integration } x = \int \frac{dq}{\sqrt{(2 \int Q dq + c)}} + c'.$$

But since $\frac{d^2 y}{dx^2} = q$, we have $\frac{dy}{dx} = \int q dx$, or substituting for dx its value

$$\frac{dy}{dx} = \int \frac{q dq}{\sqrt{(2 \int Q dq + c)}} + c'', \text{ and } dy = dx \left(\int \frac{q dq}{\sqrt{(2 \int Q dq + c)}} + c'' \right).$$

Integral
Calculus.

or replacing again dx by its value and integrating $y = \int \frac{dq}{\sqrt{(2 \int Q dq + c)}} \left\{ \int \frac{q dq}{\sqrt{(2 \int Q dq + c)}} + c'' \right\} + c'''$. Part III.

Eliminating then q between this value of y and the value of x , the required integral is obtained with four arbitrary constants.

Example 1. Let $a^2 d^2 y + y dx^2 = 0$ be the proposed equation. We have first $\frac{d^2 y}{dx^2} = -\frac{y}{a^2}$; multiplying by dy and integrating we find

$$\frac{dy^2}{dx^2} = -\frac{y^2}{a^2} + c^2, \text{ or } dx = \frac{a dy}{\sqrt{(a^2 c^2 - y^2)}}, \text{ and } x = a \sin^{-1} \frac{y}{ac} + c'$$

a value from which it is easy to derive

$$y = c \sin \frac{x}{a} + c' \cos \frac{x}{a},$$

c and c' being two new arbitrary constants.

Example 2. Let $\frac{a^2 d^4 y}{dx^4} = \frac{d^2 y}{dx^2}$ be the proposed equation. Making $\frac{d^2 y}{dx^2} = q$, we shall have successively $\frac{a^2 d^2 q}{dx^2} = q$, $\frac{a^2 dq}{dx} \frac{dq}{dx} = q dq$, $\frac{dq^2}{dx^2} = \frac{q^2 + c}{a^2}$, $dx = \frac{a dq}{\sqrt{(q^2 + c)}}$, $x = a l \left\{ \frac{q + \sqrt{(q^2 + c)}}{c'} \right\}$. Now $\frac{d^2 y}{dx^2} = q$, hence $\frac{dy}{dx} = \int q dx = \int \frac{a q dq}{\sqrt{(q^2 + c)}} = a \sqrt{(q^2 + c)} + c''$, $dy = \{a \sqrt{(q^2 + c)} + c''\} dx = a^2 dq + \frac{a c'' dq}{\sqrt{(q^2 + c)}}$,

$$y = a^2 q + a c' l \{q + \sqrt{(q^2 + c)}\} + c'''. \text{ The value of } x \text{ gives } c' e^{\frac{x}{a}} = q + \sqrt{(q^2 + c)},$$

$$\text{and } \frac{1}{c' e^{\frac{x}{a}}} = \frac{e^{-\frac{x}{a}}}{c'} = \frac{1}{q + \sqrt{(q^2 + c)}} = \frac{q - \sqrt{(q^2 + c)}}{-c}, \text{ or } -\frac{c e^{-\frac{x}{a}}}{c'} = q - \sqrt{(q^2 + c)};$$

by addition

$$q = \frac{c'}{2} e^{\frac{x}{a}} - \frac{c}{2c'} e^{-\frac{x}{a}};$$

this being substituted in the value of y , as well as $l \{q + \sqrt{(q^2 + c)}\} = \frac{x}{a} + l c'$, we get

$$y = \frac{a^2 c'}{2} e^{\frac{x}{a}} - \frac{a^2 c}{2c'} e^{-\frac{x}{a}} + c'' + c' l c' + c''' = c e^{\frac{x}{a}} + c' e^{-\frac{x}{a}} + c' x + c''''$$

(134.) When a differential equation of the n^{th} order contains only one of the variables, x and y , it can easily be reduced to another of the order $n - 1$.

If the variable which enters the equation is x , it is sufficient to make $\frac{dy}{dx} = p$, for then $\frac{d^2 y}{dx^2} = \frac{d^{n-1} p}{dx^{n-1}}$, and the proposed equation is transformed into an equation of the order $n - 1$, between the variables x and p . If it can be integrated and resolved with respect to p , the equation $y = \int p dx$ will give the relation between x and y ; if it can be resolved with respect to x , then $y = \int p dx$ will give the value of y in terms of p , and by eliminating this last quantity between the values of x and y , the integral will be obtained.

If instead of x it was y that entered the equation, we should in general substitute for the values of $\frac{dy}{dx}$, $\frac{d^2 y}{dx^2}$, &c. their values in terms of $\frac{dx}{dy}$, $\frac{d^2 x}{dy^2}$, &c. which have been given in the Differential Calculus, and then proceed as in the preceding case. We could obtain the integral in a different manner, if the proposed equation was only of the second order. Making $p = \frac{dy}{dx}$, we would have $\frac{d^2 y}{dx^2} = \frac{dp}{dx} = \frac{p dp}{dy}$, and in substituting these values the transformed equation would only contain p , dp , y and dy , if it could be integrated, and if we could derive from the integral the value of y in terms of p , or the value of p in terms of y , the values of x would be given by the formulæ

$$x + \frac{y}{p} = \int \frac{y dp}{p^2}, \quad x = \int \frac{dy}{p}.$$

We shall now apply these general notions to a few examples.

Example 1. Let the proposed equation be $\frac{(dx^2 + dy^2)^{\frac{3}{2}}}{dx dx^2 y} = X$, X being a function of X alone. Putting p

Integral Calculus. instead of $\frac{dy}{dx}$, it becomes $\frac{(1+p^2)^{\frac{3}{2}}}{dp} = X$, or $\frac{dx}{X} = \frac{dp}{(1+p^2)^{\frac{3}{2}}}$, and, consequently, $\int \frac{dx}{X} + c = \frac{p}{\sqrt{1+p^2}}$.

Let $\int \frac{dx}{X} + c = V$, then $p = \frac{V}{\sqrt{1-V^2}}$, and $y = \int p dx = \int \frac{V dx}{\sqrt{1-V^2}} + c$.

Example 2. Let the equation be $dx(dx^2 + dy^2) + xdyd^2y = ad^2y\sqrt{dx^2 + dy^2}$,
or $dx(1+p^2) + xpd p = ad p \sqrt{1+p^2}$.

If we divide both sides by $\sqrt{1+p^2}$, we find $dx\sqrt{1+p^2} + \frac{xpd p}{\sqrt{1+p^2}} = ad p$,

the left side is clearly the differential of $x\sqrt{1+p^2}$, and therefore $x\sqrt{1+p^2} = ap + c$,

$$x = \frac{ap+c}{\sqrt{1+p^2}}, \quad dx = \frac{adp(1+p^2) - (ap+c)pdp}{(1+p^2)^{\frac{3}{2}}} = \frac{(a-cp)dp}{(1+p^2)^{\frac{3}{2}}};$$

$$\text{but } dy = \int p dx, \text{ therefore } y = \int \frac{(ap - cp^2)dp}{(1+p^2)^{\frac{3}{2}}} = \frac{cp-a}{\sqrt{1+p^2}} - cl \left\{ \frac{p + \sqrt{1+p^2}}{c'} \right\},$$

and substituting for p its value derived from x , we find

$$y = \sqrt{a^2 + c^2 - x^2} - cl \left\{ \frac{c + \sqrt{a^2 + c^2 - x^2}}{c'(x-a)} \right\}.$$

Example 3. Let the equation be $(a^2 dy^2 + x^2 dx^2) d^2y = nx dx^3 dy$, or $(a^2 p^2 + x^2) dp = np x dx$. This equation is homogeneous, and if we assume $x = pu$, it becomes $\frac{dp}{p} = \frac{n u du}{a^2 + (1-n)u^2}$, and by integration

$$lp = \frac{n}{2(1-n)} l(a^2 + (1-n)u^2) + lc, \text{ hence } p = c \{ a^2 + (1-n)u^2 \}^{\frac{n}{2(1-n)}},$$

$$\text{or } x = pu = cu \{ a^2 + (1-n)u^2 \}^{\frac{n}{2(1-n)}}, \text{ but } y = \int x dp = c^2 u \{ a^2 + (1-n)u^2 \}^{\frac{n}{2(1-n)}} - nc \int u^2 du \{ a^2 + (1-n)u^2 \}^{\frac{2n-1}{2(1-n)}} + c'.$$

$$\text{If } n = 1, \text{ we have } \frac{dp}{p} = \frac{u du}{a^2}, \quad lp = \frac{u^2}{2a^2} + lc, \quad u = a \left(2l \frac{p}{c} \right)^{\frac{1}{2}},$$

$$\text{and } y = ap \sqrt{2l \frac{p}{c}}, \quad y = ap^2 \sqrt{2l \frac{p}{c}} - a \int p dp \sqrt{2l \frac{p}{c}} + c'.$$

Example 4. Let y be now the variable contained in the proposed equation, and let that equation be only of the second order, $ab d^2y = dx \sqrt{y^2 dx^2 + a^2 dy^2}$. In this case we substitute p for $\frac{dy}{dx}$, and $p \frac{dp}{dy}$ for $\frac{d^2y}{dx^2}$, the equation then becomes $\frac{ab p dp}{dy} = \sqrt{y^2 + a^2 p^2}$, an equation which is homogeneous with respect to q and p , the variables will be separated by assuming $y = pu$; this substitution gives after reduction

$$\frac{dy}{y} = \frac{ab du}{abu - u^2 \sqrt{a^2 + u^2}}.$$

To integrate the right side, make $\sqrt{a^2 + u^2} = su$, we shall have

$$u^2 = \frac{a^2}{s^2 - 1}, \quad \frac{du}{u} = \frac{-s ds}{s^2 - 1}, \quad \frac{dy}{y} = \frac{-bs ds}{bs^2 - as - b} = \frac{-s ds}{s^2 - 2ns - 1},$$

if $\frac{a}{b} = 2n$ the right side of this last equation may easily be decomposed into two fractions in observing that

$$s^2 - 2ns - 1 = (s - n - \sqrt{n^2 + 1})(s - n + \sqrt{n^2 + 1}),$$

$$\text{we shall get } \frac{2dy \sqrt{n^2 + 1}}{y} = \frac{-ds(n + \sqrt{n^2 + 1})}{s - n - \sqrt{n^2 + 1}} + \frac{ds(n - \sqrt{n^2 + 1})}{s - n + \sqrt{n^2 + 1}},$$

$$\text{and by integrating } y^{2\sqrt{n^2+1}} = \frac{c(s - n + \sqrt{n^2 + 1})^{n - \sqrt{n^2+1}}}{(s - n - \sqrt{n^2 + 1})^{n + \sqrt{n^2+1}}}.$$

But we have supposed $y = pu$, hence $dx = \frac{u dy}{y}$, and therefore by substituting for u and $\frac{dy}{y}$ their values in s , we

Integral
Calculus.

shall find $dx = \frac{-asds}{(s^2 - 2ns - 1)\sqrt{(s^2 - 1)}}$; integrating this formula, and eliminating s , we shall obtain the

relation between s and y .

(135.) Among the differential equations which contain both variables x and y , those which may be considered as homogeneous not only with respect to x and y , but also with respect to dx , dy , d^2y , &c., can be easily transformed into others which contain only one of the primitive variables. In this supposition the dimension of $\frac{dy}{dx}$ is 0, that of $\frac{d^2y}{dx^2}$ is -1, &c. Two examples will be sufficient to show what are the substitutions and transformations to be used in this case.

Example 1. Let the equation be $x^2 d^2y = x dx dy + 3y dx^2$, make $y = ux$, $\frac{dy}{dx} = p$, and $\frac{d^2y}{dx^2} = q = \frac{v}{x}$.

All the terms of the transformed will be divisible by the same power of x , and we shall find $xv = px + 3ux$,

or $v = p + 3u$; but since $\frac{v}{x} = q$, $\frac{dp}{dx} = \frac{v}{x}$, or $\frac{dx}{x} = \frac{dp}{v} = \frac{dp}{p + 3u}$, we have also $p dx = d(ux) = u dx + x du$,

and, consequently, $\frac{dx}{x} = \frac{du}{p - u}$, therefore $\frac{dp}{p + 3u} = \frac{du}{p - u}$, or $(p + 3u) du = (p - u) dp$. This is a differential equation of the first order; it is homogeneous and can easily be integrated; the integral is immediately obtained, if we observe, that by transposing the terms the equation becomes $p du + u dp = p dp - 3u du$,

each side of which is an exact differential; integrating we get $pu = \frac{p^2}{2} - \frac{3u^2}{2} + c$, from which $p = u + \sqrt{(c + 4u^2)}$,

putting c for $-2c$. Substituting this value of p in the equation $\frac{dx}{x} = \frac{du}{p - u}$, we shall find

$$\int \frac{dx}{x} = \int \frac{du}{\sqrt{(c + 4u^2)}} = \frac{1}{2} \int \frac{2u + \sqrt{(c + 4u^2)}}{c'} \quad \text{or} \quad \int \frac{dx}{x} = \frac{1}{2} \int \frac{u + \sqrt{(c + u^2)}}{c'} \quad \text{or} \quad \int \frac{dx}{x} = \frac{1}{2} \int \frac{u + \sqrt{(c + u^2)}}{c'}$$

putting $4c$ for c . Hence $x^2 = \frac{u + \sqrt{(c + u^2)}}{c'} = \frac{y + \sqrt{(cx^2 + y^2)}}{c'x}$, or $cx^2y = x^4 + c'$, by changing the constants.

Example 2. Let the equation be

$$(dx^2 + dy^2)^{\frac{3}{2}} = n dx d^2y \sqrt{(x^2 + y^2)}$$

and let

$$y = ux, \quad \frac{dy}{dx} = p, \quad \frac{d^2y}{dx^2} = q = \frac{v}{x},$$

the equation becomes

$$(1 + p^2)^{\frac{3}{2}} = nv \sqrt{(1 + u^2)}, \quad \text{or} \quad v = \frac{(1 + p^2)^{\frac{3}{2}}}{n \sqrt{(1 + u^2)}};$$

but we have as before $\frac{dp}{v} = \frac{du}{p - u}$; substituting the value of v , we shall have a differential equation of the first order in p and u ,

$$n(p - u) dp \sqrt{(1 + u^2)} = (1 + p^2)^{\frac{3}{2}} du.$$

In order to integrate this equation we shall make $p = \tan \theta$, $u = \tan \phi$, then $dp = \frac{d\theta}{\cos^2 \theta}$, $du = \frac{d\phi}{\cos^2 \phi}$,

$\sqrt{(1 + u^2)} = \frac{1}{\cos \phi}$, $(1 + p^2)^{\frac{3}{2}} = \frac{1}{\cos^3 \theta}$, $p - u = \tan \theta - \tan \phi = \frac{\sin(\theta - \phi)}{\cos \theta \cos \phi}$; these values being substituted give $n \sin(\theta - \phi) d\theta = d\phi$. Let $\theta = \phi + \psi$, and eliminate ϕ , we shall get $d\theta = \frac{d\psi}{1 - n \sin \psi}$. At the

same time we have

$$\frac{dx}{x} = \frac{du}{p - u} = \frac{d\phi \cos \theta}{\cos \phi \sin \psi} = \frac{d\phi \cos \psi}{\sin \psi} - \frac{d\phi \sin \phi}{\cos \phi},$$

or by putting $d\phi$ its value

$$d\theta - d\psi = \frac{d\psi}{1 - n \sin \psi} - d\psi = \frac{n \sin \psi d\psi}{1 - n \sin \psi},$$

we get

$$\frac{dx}{x} = \frac{n \cos \psi d\psi}{1 - n \sin \psi} - \frac{d\phi \sin \phi}{\cos \phi},$$

and in integrating

$$x = \frac{c \cos \phi}{1 - n \sin \psi}, \quad \text{and} \quad y = ux = \frac{c \sin \phi}{1 - n \sin \psi}.$$

These values joined to

$$\phi = \int \frac{n \sin \psi d\psi}{1 - n \sin \psi}$$

will give by the elimination of ψ the integral of the proposed equation.

Integral
Calculus.

(136.) The same kind of transformation will succeed if the proposed equation should become homogeneous by considering $y \frac{dy}{dx}$, $\frac{d^2 y}{dx^2}$, &c. and its differentials as being respectively of n , $n-1$, $n-2$, &c. dimensions. Part III.

In that case, supposing the proposed equation of the second order, we shall make

$$y = x^n u, \quad \frac{dy}{dx} = p = t x^{n-1}, \quad \text{and} \quad \frac{d^2 y}{dx^2} = q = v x^{n-2}.$$

These values being substituted will give an equation in which x will disappear, and by means of which we shall be able to obtain the value of v in function of t and u . Then we have

$$dy = x^n du + n x^{n-1} u dx = x^{n-1} t dx, \\ d^2 y = (n-1) x^{n-2} t dx^2 + x^{n-1} dt dx = v x^{n-2} dx^2.$$

consequently

The first of these equations gives

$$\frac{dx}{x} = \frac{du}{t - nu},$$

and the second

$$\frac{dx}{x} = \frac{dt}{v - (n-1)t};$$

and, therefore,

$$du(v - (n-1)t) = dt(t - nu);$$

and by putting for v its value in terms of t and u , we get a differential equation of the first order, which being integrated will easily lead to the integral of the proposed.

Example. Let the proposed equation be

$$x^4 d^2 y = x^3 dx dy + 2xy dx dy - 4y^2 dx^2, \quad \text{or} \quad x^4 q = x^3 p + 2xy p - 4y^2.$$

We shall make

$$y = x^2 u, \quad p = tx, \quad \text{and} \quad q = v,$$

the equation becomes

$$v = t + 2ut - 4u^2;$$

then we have

$$dy = x^2 du + 2ux dx = p dx = tx dx,$$

hence

$$\frac{dx}{x} = \frac{du}{t - 2u}.$$

We have also

$$dp = t dx + x dt = q dx = v dx \quad \text{and} \quad \frac{dx}{x} = \frac{dt}{v - t} = \frac{dt}{2ut - 4u^2},$$

therefore

$$\frac{du}{t - 2u} = \frac{dt}{2ut - 4u^2},$$

or

$$2u du(t - 2u) = dt(t - 2u).$$

This equation is satisfied by making $2u du = dt$, which gives $t = u^2 + c$, or by $t = 2u$. The first value of t being substituted in the expression of $\frac{dx}{x}$, we get

$$\frac{dx}{x} = \frac{du}{u^2 - 2u + c}.$$

The integral of the right side of this equation will assume three different forms according as c is less, equal, or greater than one. Let, first, $c = 1$; then

$$\frac{dx}{x} = \frac{du}{(u-1)^2} \quad \text{and} \quad lx = \frac{1}{1-u} + c', \quad \text{or} \quad lx = \frac{x^2}{x^2 - y} + c.$$

Let, secondly, $c = 1 - e^2$; then $\frac{dx}{x} = \frac{du}{(u-1)^2 - e^2}$ and $lx = -\frac{1}{2e} l\left(\frac{e+u-1}{e-u+1}\right) + l c'$,

or

$$x = c' \left\{ \frac{(e+1)x^2 - y}{(e-1)x^2 + y} \right\}^{\frac{1}{2e}}.$$

Thirdly, let $c = 1 + e^2$, and we shall get

$$l \frac{x}{c'} = \frac{1}{e} \tan^{-1} \frac{y - x^2}{e x^2}.$$

The second value of t , $t = 2u$ being substituted in the expression of $\frac{dx}{x}$, gives

$$du = 0, \quad \text{or} \quad u = c, \quad \text{that is} \quad y = c x^2.$$

This value of y satisfies the proposed equation; but as it cannot be derived from the complete integral we have obtained above by assuming a particular value for one of the arbitrary constants, it ought to be considered as a particular integral.

(137.) The order of a differential equation, in which y and its differential coefficients amount to the same dimensions in every term, may be reduced by only a very simple substitution. It is sufficiently evident, that if in such an equation we assume $y = e^{\int u dx}$, every term will become divisible by a power of $e^{\int u dx}$ equal to the

Integral
Calculus.

dimension of each term, since the values of dy , d^2y , &c. will be all multiplied by $e^{f'x}$; and besides that the expression of dy derived from $y = e^{\int u dx}$, containing only u , that of d^2y , only the first differential of u , &c. the order of the transformed equation will be less by one than that of the proposed. Part III.

Example. Let $xy dy^2 = y dx dy + x dy^2 + \frac{bx dy^2}{\sqrt{(a^2 - x^2)}}$ be the proposed equation. Make $y = e^{\int u dx}$, and the equation becomes

$$du + u^2 dx = \frac{u dx}{x} + u^2 dx + \frac{bu^2 dx}{\sqrt{(a^2 - x^2)}}$$

or

$$\frac{x du - u dx}{u^2} = \frac{bx dx}{\sqrt{(a^2 - x^2)}}$$

each of which equations is an exact differential, and which being integrated gives

$$u = \frac{x}{c + b\sqrt{(a^2 - x^2)}},$$

$$\text{and } \log y = \int u dx = \int \frac{x dx}{c + b\sqrt{(a^2 - x^2)}} = -\frac{\sqrt{(a^2 - x^2)}}{b} + \frac{c}{b^2} l. \left(\frac{c + b\sqrt{(a^2 - x^2)}}{c} \right).$$

(138.) We have given the name of *linear equation* of the first order to equations of the form

$$dy + P y dx = Q,$$

when P and Q are functions of x alone. There are also linear equations of all orders. Their general form is

$$d^n y + P d^{n-1} y dx + Q d^{n-2} y dx^2 + \dots + U y dx^n = V dx^n,$$

where $P, Q, \dots, U, V$ are functions of x alone.

This equation being homogeneous with respect to y and its differential coefficients dy, d^2y , and when $V = 0$, we may, in that case, as in the preceding paragraph, reduce the integration to that of an equation of an order less by one, by assuming $y = e^{\int t dx}$.

The proposed equation, in the supposition of $V = 0$, is

$$d^n y + P d^{n-1} y dx + Q d^{n-2} y dx^2 + \dots + U y dx^n = 0.$$

Let $y_1, y_2, y_3, \dots, y_n$ be n particular values of y , which satisfy this equation, then it may easily be proved that the general integral will be

$$y = c_1 y_1 + c_2 y_2 + \dots + c_n y_n,$$

$c_1, c_2, \dots, c_n$ being n arbitrary constants.

Since $y = y_1$ satisfies the proposed equation, we have

$$d^n y_1 + P d^{n-1} y_1 dx + Q d^{n-2} y_1 dx^2 + \dots + U y_1 dx^n = 0,$$

and in the same manner for the other values y_2, y_3 , &c.

$$d^n y_2 + P d^{n-1} y_2 dx + Q d^{n-2} y_2 dx^2 + \dots + U y_2 dx^n = 0,$$

$$\dots \dots \dots$$

$$d^n y_n + P d^{n-1} y_n dx + Q d^{n-2} y_n dx^2 + \dots + U y_n dx^n = 0.$$

Therefore if we multiply these equations respectively by $c_1, c_2, \dots, c_n$, and then add them, we shall have identically

$$\left. \begin{aligned} &c_1 (d^n y_1 + P d^{n-1} y_1 dx + Q d^{n-2} y_1 dx^2 + \dots + U y_1 dx^n) \\ &+ c_2 (d^n y_2 + P d^{n-1} y_2 dx + Q d^{n-2} y_2 dx^2 + \dots + U y_2 dx^n) \\ &\dots \dots \dots \\ &+ c_n (d^n y_n + P d^{n-1} y_n dx + Q d^{n-2} y_n dx^2 + \dots + U y_n dx^n) \end{aligned} \right\} = 0.$$

But the left side of this last equation is precisely the result we would obtain, if we were to substitute in the proposed equation the value

$$y = c_1 y_1 + c_2 y_2 + \dots + c_n y_n;$$

and since the result of this substitution is identically equal to nothing, and that the value of y contains n arbitrary constants, it may be considered as the complete integral of the proposed equation. The difficulty of integrating is, therefore, reduced to the determination of n particular values.

When $P, Q, \dots, U$ are constant quantities, these n particular values can easily be discovered. Make in that supposition $y = e^{mx}$, we may take m constant for since

$$\frac{dy}{dx} = e^{mx} \cdot m, \quad \frac{d^2y}{dx^2} = e^{mx} \cdot m^2, \dots, \frac{d^n y}{dx^n} = e^{mx} \cdot m^n.$$

We shall have to determine m after substituting these values in the proposed, and dividing by e^{mx} , the equation

$$m^n + P m^{n-1} + Q m^{n-2} + \dots + U = 0,$$

Integral Calculus. where $P, Q, \dots, U$ are constant quantities; therefore the value of m derived from it will be constant, as we have supposed it. This equation will give n values of m ; let us suppose, first, that they are all real and unequal, and let them be represented by $m_1, m_2, m_3, \dots, m_n$, then the n values of $y, e^{m_1 x}, e^{m_2 x}, \dots, e^{m_n x}$, are n particular solutions of the proposed equation, therefore

$$y = c_1 e^{m_1 x} + c_2 e^{m_2 x} + \dots + c_n e^{m_n x}$$

is the complete integral, $c_1, c_2, \dots, c_n$ being n arbitrary constants.

This integral may assume different forms. We shall make the transformations in the supposition of $n = 3$, and it will be easy to extend the same method to every case. We have, then,

$$y = c_1 e^{m_1 x} + c_2 e^{m_2 x} + c_3 e^{m_3 x}.$$

Putting $e^{m_3 x}$ as a common factor, this value becomes

$$y = e^{m_3 x} (c_3 + c_2 e^{(m_2 - m_3)x} + c_1 e^{(m_1 - m_3)x});$$

substituting for the constants c_2 and c_1 other constants

$$\frac{c_2}{m_2 - m_3} = \frac{c_1}{(m_1 - m_2)(m_1 - m_3)},$$

and observing that

$$e^{(m_2 - m_3)x} = m_2 - m_3 \int e^{(m_2 - m_3)x} dx,$$

we get

$$y = e^{m_3 x} \left\{ c_3 + c_2 \int e^{(m_2 - m_3)x} dx - \frac{c_1}{(m_1 - m_2)(m_1 - m_3)} e^{(m_1 - m_3)x} \right\}.$$

But therefore

$$e^{(m_1 - m_3)x} = e^{(m_2 - m_3)x} \cdot e^{(m_1 - m_2)x}, \text{ and } (m_2 - m_3) = (m_1 - m_2) - (m_1 - m_3),$$

$$\begin{aligned} \frac{c_1}{(m_1 - m_2)(m_1 - m_3)} e^{(m_1 - m_3)x} &= \frac{c_1 (m_2 - m_3) e^{(m_1 - m_3)x}}{(m_1 - m_2)(m_1 - m_3)(m_2 - m_3)} = \frac{c_1 (m_1 - m_2) e^{(m_2 - m_3)x} \cdot e^{(m_1 - m_2)x}}{(m_1 - m_2)(m_1 - m_3)(m_2 - m_3)} \\ &\quad - \frac{c_1 (m_1 - m_3) e^{(m_2 - m_3)x} \cdot e^{(m_1 - m_2)x}}{(m_1 - m_2)(m_1 - m_3)(m_2 - m_3)}, \\ &= -c_1 \int e^{(m_2 - m_3)x} \cdot dx \times \int e^{(m_1 - m_2)x} \cdot dx + \dots + c_1 \int \left(\frac{e^{(m_2 - m_3)x} \cdot e^{(m_1 - m_2)x}}{(m_2 - m_3)} \cdot dx \right) \\ &= -c_1 \int \{ e^{(m_2 - m_3)x} \cdot \int e^{(m_1 - m_2)x} \cdot dx \}, \end{aligned}$$

which value being substituted, gives, finally,

$$y = e^{m_3 x} \left\{ c_3 + \int e^{(m_2 - m_3)x} \{ c_2 dx + \int e^{(m_1 - m_2)x} \{ c_1 dx^2 \right\}.$$

And for any value of n we shall have

$$y = e^{m_n x} \left\{ c_n + \int e^{(m_{n-1} - m_n)x} \{ c_{n-1} dx + \int e^{(m_{n-2} - m_{n-1})x} \{ c_{n-2} dx^2 + \dots \{ c_2 dx + \int e^{(m_1 - m_2)x} \{ c_1 dx^n \right\}.$$

We could have put as a common factor instead of $e^{m_n x}$ any other particular value of

$$y, e^{m_{n-1} x}, \text{ or } e^{m_{n-2} x}, \&c.;$$

to each factor would correspond a value of y , different in appearance from all the others, but in reality differing only by the values of the constants, since they are all deduced from the value

$$y = c_1 e^{m_1 x} + c_2 e^{m_2 x} + c_3 e^{m_3 x} + \dots + c_n e^{m_n x}.$$

The new form of the value of y we have obtained is more complicated than the other, but it has the advantage of applying to the cases in which the equation

$$m^n + P m^{n-1} + Q m^{n-2} + \dots + U = 0$$

has equal roots, whilst the other does not without transformation. When $n = 3$, if the two roots m_1 and m_2 are equal, the formula gives

$$y = e^{m_3 x} \{ c_3 + \int e^{(m_2 - m_3)x} \{ c_2 dx + \int c_1 dx^2,$$

or performing the integrations

$$y = c''' e^{m_3 x} + c'' e^{m_2 x} + c' x e^{m_2 x},$$

in making

$$c''' = c_3, \quad c'' = \frac{c_2}{m_2 - m_3} - \frac{c_3}{(m_2 - m_3)^2}, \quad c' = \frac{c_1}{m_2 - m_3}.$$

We would have obtained a result differing only by the constants from the preceding, if we had assumed $m_2 = m_3$, instead of $m_1 = m_2$.

When the three roots m_1, m_2, m_3 are equal to one another, the same formula gives

$$y = c''' e^{m_3 x} + c'' x e^{m_2 x} + c' x^2 e^{m_1 x},$$

substituting c''' , c'' , c' for the constant quantities c_3 , c_2 , and $\frac{c_1}{2}$.

If among the roots of the equation

$$m^n + P m^{n-1} + Q m^{n-2} + \dots + U = 0,$$

there are some which are imaginary, the expressions we have obtained for the general integral contain terms affected with imaginary quantities; but it is easy to transform them into others containing only real terms, by substituting for the exponential their values in function of sines and cosines.

If m_1 and m_2 , for instance, are imaginary values, they will be of the form $a + \phi \sqrt{-1}$, $a - \phi \sqrt{-1}$, and the two terms $c_1 e^{m_1 x}$, $c_2 e^{m_2 x}$ of the integral which correspond to these roots will become

$$c_1 e^{(a+\phi\sqrt{-1})x} + c_2 e^{(a-\phi\sqrt{-1})x},$$

and by successive transformations

$$c_1 e^{ax} \cdot e^{\phi\sqrt{-1}x} + c_2 e^{ax} \cdot e^{-\phi\sqrt{-1}x},$$

$$c_1 e^{ax} (\cos \phi x + \sqrt{-1} \sin \phi x) + c_2 e^{ax} (\cos \phi x - \sqrt{-1} \sin \phi x),$$

$$e^{ax} \{ (c_1 + c_2) \cos \phi x + (c_1 - c_2) \sqrt{-1} \sin \phi x \};$$

and making

$$c_1 + c_2 = c', \quad \text{and} \quad (c_1 - c_2) \sqrt{-1} = c''$$

the aggregate of the two terms assumes the simple form

$$e^{ax} (c' \cos \phi x + c'' \sin \phi x).$$

Similar transformations would obviously apply to the case in which there should be equal imaginary roots, but we should in that case make use of the second form of the general integral we have given.

(139.) When the coefficients P , Q , &c. are not constant, there is no general process by means of which n particular values of the integral can be found. But if they can be discovered by any means, they not only give immediately the value of the general integral of the differential equation

$$d^n y + P d y^{n-1} dx + Q d^2 y dx^2 + \&c. \dots + U y dx^n = 0 \dots (a),$$

but from them may also be deduced the general integral of

$$d^n y + P d^{n-1} y dx + Q d^{n-2} y dx^2 + \dots + U y dx^n = V dx^n \dots (b).$$

We have already proved that $y_1, y_2, y_3, \dots, y_n$, being n particular values which satisfy equation (a), the integral general of that equation is

$$y = c_1 y_1 + c_2 y_2 + \dots + c_n y_n,$$

where $c_1, c_2, \dots, c_n$ are arbitrary constants. Now it is obvious that whatever may be the general integral of equation (b), it may be supposed to be still represented by

$$y = c_1 y_1 + c_2 y_2 + \dots + c_n y_n$$

provided we suppose $c_1, c_2, \dots, c_n$ to be functions of x instead of being arbitrary constants; and the question is thus reduced to discover what functions of x should be substituted for c_1, c_2, c_3 , in order that the value

$$y = c_1 y_1 + c_2 y_2 + \dots + c_n y_n$$

should satisfy equation (b). We shall show how this can be done for an equation of the third order,

$$d^3 y + P d^2 y dx + Q d y dx^2 + R y dx^3 = V dx^3,$$

and the method we shall make use of may without difficulty be extended to any order.

Let y_1, y_2, y_3 be the three particular values which satisfy the equation

$$d^3 y + P d^2 y dx + Q d y dx^2 + R y dx^3 = 0,$$

then we are to determine

$$c_1, c_2, c_3, \text{ so that } y = c_1 y_1 + c_2 y_2 + c_3 y_3$$

shall satisfy the proposed equation. We have thus only one condition to determine three quantities, and therefore we may choose ourselves two other conditions. We shall find, by differentiating the value of y ,

$$d y = c_1 d y_1 + c_2 d y_2 + c_3 d y_3 + y_1 d c_1 + y_2 d c_2 + y_3 d c_3.$$

For the first of the two conditions we may dispose of, we shall make

$$y_1 d c_1 + y_2 d c_2 + y_3 d c_3 = 0,$$

and the value of $d y$ will become

$$d y = c_1 d y_1 + c_2 d y_2 + c_3 d y_3.$$

Differentiating again, we find

$$d^2 y = c_1 d^2 y_1 + c_2 d^2 y_2 + c_3 d^2 y_3 + d y_1 d c_1 + d y_2 d c_2 + d y_3 d c_3;$$

and if we take for the second condition

Integral
Calculus.

this expression will be reduced to

$$d y_1 d c_1 + d y_2 d c_2 + d y_3 d c_3 = 0,$$

$$d^2 y = c_1 d^2 y_1 + c_2 d^2 y_2 + c_3 d^2 y_3.$$

A new differentiation will give

$$d^3 y = c_1 d^3 y_1 + c_2 d^3 y_2 + c_3 d^3 y_3 + d c_1 d^2 y_1 + d c_2 d^2 y_2 + d c_3 d^2 y_3.$$

 The values of y , $d y$, $d^2 y$, $d^3 y$, being now substituted in the proposed equation, it will become

$$\left. \begin{aligned} & c_1 (d^3 y_1 + P d^2 y_1 d x + Q d y_1 d x^2 + R y_1 d x^3) \\ & + c_2 (d^3 y_2 + P d^2 y_2 d x + Q d y_2 d x^2 + R y_2 d x^3) \\ & + c_3 (d^3 y_3 + P d^2 y_3 d x + Q d y_3 d x^2 + R y_3 d x^3) \\ & + d^2 y_1 d c_1 + d^2 y_2 d c_2 + d^2 y_3 d c_3 \end{aligned} \right\} = V d x^3.$$

This equation becomes simply

$$d^2 y_1 d c_1 + d^2 y_2 d c_2 + d^2 y_3 d c_3 = V d x^3,$$

 since y_1 , y_2 , y_3 are particular values which satisfy the equation

$$d^3 y + P d^2 y d x + Q d y d x^2 + R y d x^3 = 0.$$

 We have thus between the differentials $d c_1$, $d c_2$, $d c_3$, the three equations

$$y_1 d c_1 + y_2 d c_2 + y_3 d c_3 = 0,$$

$$d y_1 d c_1 + d y_2 d c_2 + d y_3 d c_3 = 0,$$

$$d^2 y_1 d c_1 + d^2 y_2 d c_2 + d^2 y_3 d c_3 = 0,$$

 from which we shall derive the values of these differentials in terms of x , when those of y_1 , y_2 , y_3 are known; if $X_1 d x$, $X_2 d x$, $X_3 d x$ are the values obtained by elimination, we shall get by integrating

$$c_1 = \int X_1 d x + E_1, \quad c_2 = \int X_2 d x + E_2, \quad c_3 = \int X_3 d x + E_3,$$

and consequently

$$y = y_1 (\int X_1 d x + E_1) + y_2 (\int X_2 d x + E_2) + y_3 (\int X_3 d x + E_3)$$

will be the complete integral of

$$d^3 y + P d^2 y d x + Q d y d x^2 + R y d x^3 = V d x^3.$$

 If only two particular values y_1 , y_2 were known, then in representing the general value of y by $c_1 y_1 + c_2 y_2$, the determination of c_1 and c_2 would require the integration of a differential equation of the second order, which may be reduced to a linear equation of the first order. In that case we have

$$d y = c_1 d y_1 + c_2 d y_2 + y_1 d c_1 + y_2 d c_2,$$

and since there are only two quantities to be determined, we can assume only one relation between them; if we make

$$y_1 d c_1 + y_2 d c_2 = 0,$$

 the value of $d y$ will simply be

$$c_1 d y_1 + c_2 d y_2,$$

and two successive differentiations will give

$$d^2 y = c_1 d^2 y_1 + c_2 d^2 y_2 + d y_1 d c_1 + d y_2 d c_2,$$

$$d^3 y = c_1 d^3 y_1 + c_2 d^3 y_2 + 2 d^2 y_1 d c_1 + 2 d^2 y_2 d c_2 + d y_1 d^2 c_1 + d y_2 d^2 c_2;$$

these values being substituted in the proposed equation, and reduced as in the preceding case, give

$$\left. \begin{aligned} & d y_1 d^2 c_1 + d y_2 d^2 c_2 + 2 d^2 y_1 d c_1 + 2 d^2 y_2 d c_2 \\ & + P d y_1 d c_1 d x + P d y_2 d c_2 d x \end{aligned} \right\} = V d x.$$

 From this equation we may eliminate $d c_2$ and $d^2 c_2$ by means of the equation

$$y_1 d c_1 + y_2 d c_2 = 0,$$

and its differential, we shall get then an equation containing only

$$d c_1, \quad d^2 c_1, \quad \text{and } x,$$

and therefore reducible to the first order.

 Lastly. If we know only one particular value, y_1 , the same method might still be used, and the general integral represented by $c_1 y_1$; but in that case the determination of c_1 would require the integration of a differential equation of the third order, which might be reduced to the second, since it would contain only x and the differentials of c_1 .

 The result we have thus obtained for the third order may easily be extended to any order n .

 (140.) When the coefficients P , Q , R , &c. are constant, we know how to find n particular values of the equation

$$d^n y + P d^{n-1} y d x + Q d^{n-2} y d x^2 + \dots + U y d x^n = 0$$

consequently by the preceding method we shall be able to find, in that case, the general integral of

$$d^n y + P d^{n-1} y dx + Q d^{n-2} y dx^2 + \dots + U y dx^n = V dx^n.$$

Let us take, for instance, the equation of the second order

$$d^2 y + P dy dx + Q y dx^2 = V dx^2,$$

and let m_1 and m_2 be the two roots of the equation $m^2 + Pm + Q = 0$, we assume that the required integral is $y = c_1 e^{m_1 x} + c_2 e^{m_2 x}$, and we shall have to determine the values of c_1 and c_2 , the two equations

$$e^{m_1 x} d c_1 + e^{m_2 x} d c_2 = 0, \quad e^{m_1 x} m_1 d c_1 + e^{m_2 x} m_2 d c_2 = V dx,$$

which give

$$d c_1 = \frac{V e^{-m_1 x} dx}{m_1 - m_2}, \quad d c_2 = \frac{V e^{-m_2 x} dx}{m_2 - m_1},$$

and, therefore,

$$y = e^{m_1 x} \left\{ \frac{\int V e^{-m_1 x} dx}{m_1 - m_2} + E_1 \right\} + e^{m_2 x} \left\{ \frac{\int V e^{-m_2 x} dx}{m_2 - m_1} \right\}.$$

The values of $d c_1$ and $d c_2$ we have just found are of the form $A_1 e^{-m_1 x} V dx$, $A_2 e^{-m_2 x} V dx$, A_1 and A_2 being constant quantities. It may easily be proved that it is the same with all orders, for if we assume

$$d c_1 = A_1 e^{-m_1 x} V dx, \quad d c_2 = A_2 e^{-m_2 x} V dx, \dots, d c_n = A_n e^{-m_n x} V dx,$$

the equations from which the values of $d c_1$, $d c_2$, &c. are to be derived will become, in substituting at the same time for y_1 , y_2 , y_3 , &c., their values $e^{m_1 x}$, $e^{m_2 x}$, &c.

$$\left. \begin{aligned} A_1 + A_2 + A_3 + \dots + A_n &= 0 \\ m_1 A_1 + m_2 A_2 + m_3 A_3 + \dots + m_n A_n &= 0 \\ m_1^2 A_1 + m_2^2 A_2 + m_3^2 A_3 + \dots + m_n^2 A_n &= 0 \\ \dots &\dots \\ m_1^{n-1} A_1 + m_2^{n-1} A_2 + m_3^{n-1} A_3 + \dots + m_n^{n-1} A_n &= 0 \end{aligned} \right\} (A),$$

which equations will be satisfied by constant values of $m_1, m_2, \dots, m_n$. Let

$$\begin{aligned} m_2 + m_3 + \dots + m_n &= -P' \\ m_2 m_3 + m_2 m_4 + \dots &= +Q' \\ m_2 m_3 m_4 + m_2 m_3 m_5 + \dots &= -R' \\ \dots &\dots \\ m_2 m_3 m_4 \dots m_n &= \pm U' \end{aligned}$$

Then the quantities $m_2, m_3, \dots, m_n$, are the roots of the equation

$$m'^{n-1} + P' m'^{n-2} + Q' m'^{n-3} + \dots + U' = 0.$$

This understood, multiply the last but one of the equations (A) by P' , the last but two by Q' , &c., and then add them all together, we shall get

$$\left. \begin{aligned} A_1 (m_1^{n-1} + P' m_1^{n-2} + Q' m_1^{n-3} + \dots + U') \\ + A_2 (m_2^{n-1} + P' m_2^{n-2} + Q' m_2^{n-3} + \dots + U') \\ + \dots \\ + A_n (m_n^{n-1} + P' m_n^{n-2} + Q' m_n^{n-3} + \dots + U') \end{aligned} \right\} = 0.$$

It is obvious that all the lines which compose this last equation are equal to nothing except the first, and consequently

$$A_1 = \frac{1}{m_1^{n-1} + P' m_1^{n-2} + Q' m_1^{n-3} + \dots + U'}$$

or

$$A_1 = \frac{1}{(m_1 - m_2)(m_1 - m_3) \dots (m_1 - m_n)}$$

The values of $A_2, A_3, \dots, A_n$ will be obtained in the same manner.

Hence

$$d c_1 = A_1 V e^{-m_1 x}, \quad d c_2 = A_2 V e^{-m_2 x}, \text{ &c.,}$$

Integral
Calculus, and

$$y = \frac{e^{m_1 x} (E_1 + \int V e^{-m_1 x} dx)}{(m_1 - m_2)(m_1 - m_3) \dots (m_1 - m_n)} + \frac{e^{m_2 x} (E_2 + \int V e^{-m_2 x} dx)}{(m_2 - m_1)(m_2 - m_3) \dots (m_2 - m_n)} + \dots + \frac{e^{m_n x} (E_n + \int V e^{-m_n x} dx)}{(m_n - m_1)(m_n - m_2) \dots (m_n - m_{n-1})}.$$

This value may be put under another form which applies without further transformations to the case in which the equation

$$m^n + P m^{n-1} + Q m^{n-2} + \dots + U = 0$$

has equal roots. It will be sufficient to show how the transformation can be effected in the case of the second order. Then

$$y = \frac{e^{m_1 x} (E_1 + \int V e^{-m_1 x} dx)}{m_1 - m_2} + e^{m_2 x} \frac{(E_2 + \int V e^{-m_2 x} dx)}{m_2 - m_1},$$

which becomes successively

$$y = \frac{E_2 e^{m_2 x}}{m_2 - m_1} + \frac{E_1 e^{m_1 x}}{m_1 - m_2} + \frac{e^{m_2 x} \int V e^{-m_2 x} dx}{m_2 - m_1} + \frac{e^{m_1 x} \int V e^{-m_1 x} dx}{m_1 - m_2},$$

$$\text{or } y = \frac{E_2 e^{m_2 x}}{m_2 - m_1} + e^{m_2 x} \int e^{(m_1 - m_2)x} \cdot E_1 + \frac{e^{m_2 x} \int e^{(m_1 - m_2)x} V e^{-m_1 x} dx}{m_2 - m_1} - \frac{e^{m_2 x} \cdot e^{(m_1 - m_2)x} \int V e^{-m_1 x} dx}{m_2 - m_1},$$

$$\text{or } y = e^{m_2 x} \left\{ \frac{E_2}{m_2 - m_1} + \int e^{(m_1 - m_2)x} \{ E_1 dx + \int V e^{-m_1 x} dx^2 \} \right\},$$

or putting c'' and c' for $\frac{E_2}{m_2 - m_1}$ and E_1 , we find

$$y = e^{m_2 x} \{ c'' + \int e^{(m_1 - m_2)x} \{ c' dx + \int V e^{-m_1 x} dx^2 \} \}$$

and generally, by similar steps, we should find

$$y = e^{m_n x} \{ c_n + \int e^{(m_{n-1} - m_n)x} \{ c_{n-1} dx + \int e^{(m_{n-2} - m_{n-1})x} \{ c_{n-2} dx^2 + \dots + \int e^{-m_1 x} V dx^{n-1} \} \}$$

If some of the roots are impossible quantities, the imaginary, which they will introduce in the integral, may be made to disappear by means analogous to those we have already used.

If, for instance, the two roots m_1 and m_2 are impossible, and respectively equal to $a + \phi \sqrt{-1}$, $a - \phi \sqrt{-1}$, the two first terms of the general expression will become

$$\frac{e^{(a+\phi\sqrt{-1})x} \int e^{-x(a+\phi\sqrt{-1})} dx}{A + B\sqrt{-1}} + \frac{e^{(a-\phi\sqrt{-1})x} \int e^{-x(a-\phi\sqrt{-1})} dx}{A - B\sqrt{-1}}.$$

Including the arbitrary constants E_1 and E_2 under the sign of integration, reducing to the same denominator, and substituting for the imaginary exponentials their values in function of sines and cosines, the expression becomes

$$e^{ax} \frac{(2A \cos \phi x + 2B \sin \phi x) \int e^{-ax} V dx \cos \phi x}{A^2 + B^2} + e^{ax} \frac{(2A \sin \phi x - 2B \cos \phi x) \int e^{-ax} V dx \sin \phi x}{A^2 + B^2}.$$

(141.) Linear equations, in which the coefficient P , Q , &c. are functions of x , can be integrated in very few cases. We shall only mention the following equation, where P , Q , &c. are constant quantities, and where a simple transformation succeeds:

$$(a + bx)^n d^n y + P(a + bx)^{n-1} d^{n-1} y + Q(a + bx)^{n-2} d^{n-2} y + \dots + U y dx^n = V dx^n.$$

Making $a + bx = bt$, we shall have $dx = dt$, and if W represents the value assumed by V when for x , $t - \frac{a}{b}$ is substituted, and P' , Q' , &c. the values of $\frac{P}{b}$, $\frac{Q}{b^2}$, &c., the equation becomes

$$t^n d^n y + P' t^{n-1} d^{n-1} y dt + Q' t^{n-2} d^{n-2} y dt^2 + \dots + U' y dt^n = \frac{W dt^n}{b^n};$$

the integration of which depends on the determination of n particular values of

$$t^n d^n y + P' t^{n-1} d^{n-1} y dt + Q' t^{n-2} d^{n-2} y dt^2 + \dots + U' y dt^n = 0.$$

These are easily obtained, if we observe that by assuming $y = t^m$, we shall have to determine m in the equation

$$m(m-1) \dots (m-n+1) + P' m(m-1) \dots (m-n+2) \dots + U' = 0,$$

Integral
Calculus.

which will be of the n^{th} degree, giving n values for m , and consequently n particular solutions, with which we shall proceed, as before, to obtain the integral of the proposed equation. Part III.

The equation $t^n d^n y + P' t^{n-1} d^{n-1} y dt + \&c. \dots + U' y dt^n = 0$ may be transformed into a linear equation of the n^{th} order with constant coefficients. It is sufficient for that purpose to make

$$\frac{dt}{t} = du, \quad \text{then } \frac{dy}{dt} = \frac{dy}{t du},$$

and
$$\frac{d^2 y}{dt^2} = \frac{1}{t^2} \left(\frac{d^2 y}{du^2} - \frac{dy}{du} \right), \quad \frac{d^3 y}{dt^3} = \frac{1}{t^3} \left(\frac{d^3 y}{du^3} - \frac{3 d^2 y}{du^2} + \frac{2 dy}{du} \right), \&c.,$$

and the transformed equation will have, obviously, constant coefficients.

On Particular Solutions of Differential Equations.

(142.) From what has already been stated respecting the integration of differential equations, it appears that to every differential equation corresponds an infinite number of primitive equations or integrals, differing only from each other by the particular values assigned to the arbitrary constants which enter into the *general integral*. But besides these *particular integrals* there exist, in a great many cases, equations between x and y , which satisfy the proposed differential equation without being included in the complete integral, that is without being deducible from it by giving particular values to the constants. These equations not being obtained by the process of integration are called *particular solutions* of the differential equations.

The *general integral* of $y dx - x dy = n \sqrt{(dx^2 + dy^2)}$, for instance, is $y - cx = n \sqrt{(1 + c^2)}$, and it may be easily verified that the equation $x^2 + y^2 = n^2$, which cannot be deduced from it by assigning any particular value to the constant, it satisfies, however, the proposed differential equation, and is, therefore, according to the preceding definition a *particular solution* of it.

It is frequently of as much importance to determine the *particular solutions* as the *general integral*, for, in many cases the true solution of the proposed problem is to be found amongst them, and not in the general integral.

(143.) Let us first investigate the circumstances upon which depends the existence of particular solutions. Let $f\left(x, y, \frac{dy}{dx}\right) = 0$ be any differential equation of the first order, and let $u = F(x, y, a) = 0$ be the general integral, a being the arbitrary constant introduced by the integration. Then $f\left(x, y, \frac{dy}{dx}\right) = 0$ will result of the elimination of a between $u = F(x, y, a) = 0$, and its immediate differential $\frac{du}{dx} dx + \frac{du}{dy} dy = 0$.

Now, if the proposed differential equation has any *particular solution*, it is obvious that although it cannot be deduced from the general integral by substituting for the constant a any particular value, it may still be considered as included in the equation $F(x, y, a) = 0$, by supposing that a instead of representing a constant quantity, is a function of x , or of x and y . In that hypothesis, the proposed differential equation $f\left(x, y, \frac{dy}{dx}\right) = 0$, must still result from a combination of the equation $F(x, y, a) = 0$, and its immediate differential equation, which, then, is $\frac{du}{dx} dx + \frac{du}{dy} dy + \frac{du}{da} da = 0$, for otherwise $F(x, y, a) = 0$ could not be a solution of it. But we have already said that $f\left(x, y, \frac{dy}{dx}\right) = 0$ is the result of the elimination of a between $F(x, y, a) = 0$, and $\frac{du}{dx} dx + \frac{du}{dy} dy = 0$, therefore, in the case where a is supposed variable, in order that it might also result from a combination of the two equations

$$F(x, y, a) = 0, \quad \frac{du}{dx} dx + \frac{du}{dy} dy + \frac{du}{da} da = 0,$$

it is necessary that a should be such that $\frac{du}{da} da = 0$.

This equation gives $da = 0$, or $\frac{du}{da} = 0$. From the first we get $a = \text{constant}$, and therefore this value corresponds to the general integral $F(x, y, a) = 0$. But in the other equation $\frac{du}{da} = 0$, $\frac{du}{da}$ will be generally a function of x, y , and a , therefore the value of a may be derived from it in terms of x and y , and this value being substituted in the equation $F(x, y, a) = 0$, will lead to a new equation in terms of x , and y , without an arbitrary constant, generally not susceptible of being deduced from the general integral $F(x, y, a) = 0$ by substituting

Integral
Calculus.

Part III.

any particular constant value for a , and yet satisfying the differential equation $f\left(x, y, \frac{dy}{dx}\right) = 0$. Therefore this equation, or its factors, when all the terms are on one side, will be the particular solution or solutions of the proposed differential equation.

(144.) Hence when the general integral $u = F(x, y, a) = 0$ of a proposed differential equation is known, to discover the particular solutions, if there be any, it will be sufficient to eliminate a between the two equations

$$u = 0, \text{ and } \frac{du}{da} = 0.$$

(145.) The equation to which this elimination will lead, will not always, however, belong to a particular solution. To ascertain whether it does or not, it will be necessary first to eliminate one of the variables x or y ,

between the two equations $u = 0$, and $\frac{du}{da} = 0$, and to determine the value of a by means of the resulting

equation. If this value be a function of the other variable, then it is clear that by substituting this value instead of a in $u = 0$, we shall have a particular solution. But, if the value be constant, it is obvious, on the contrary, that the

substitution of that value for a will only give a particular integral. The value of $\frac{du}{da}$ may also be independent of

a . This will happen when a enters into the general integral in the first degree. In that case, the general integral must have the form $P + Qa = 0$, P and Q being functions of x, y , and not containing a . We derive

from it $\frac{du}{da} = Q$, and the elimination of a between $P + Qa = 0$, and $Q = 0$, will give either $P = 0$, or $Q = 0$.

Both these are clearly particular integrals; the first corresponding to $a = 0$, and the other to $a = \infty$. If Q be a factor of P , the result of the elimination is only $Q = 0$, and the value of a corresponding is $\frac{0}{0}$. In that case

$Q = 0$ may be considered as a particular solution, for it satisfies the differential equation, which in that case is $PdQ - QdP = 0$. But such solutions can scarcely be ranked amongst particular solutions, since by multiplying the general integral $P + Qa = 0$ by any factor R not containing a , $R = 0$ would also become a particular solution. The same observation applies to the common divisors of M and N , in a differential equation of the form $Mdx + Ndy = 0$. Each of these common divisors made equal to nothing satisfies the differential equation, and if it cannot be derived from the general integral by giving a particular value to the arbitrary constant, it may be considered as a particular solution. Such particular solutions may be found without difficulty by the determination of the common divisor between M and N , but their number may be increased without limits by introducing new common factors to M and N .

(146.) We shall apply the rule derived from what precedes to find the particular solutions, when the general integral is known, to an example. We have already seen that the general integral of

$$ydx - xdy = n\sqrt{(dx^2 + dy^2)} \text{ is } y - cx = n\sqrt{(1 + c^2)};$$

we shall have, consequently, $\frac{du}{dc} = -\left(x + \frac{nc}{\sqrt{(1 + c^2)}}\right)$; eliminating c between the general integral and

$x + \frac{nc}{\sqrt{(1 + c^2)}} = 0$, we shall find $x^2 + y^2 = n^2$, which is the particular solution. There is no occasion here to

eliminate one of the variables, to ascertain whether the value of c is constant, for the equation $x + \frac{nc}{\sqrt{(1 + c^2)}} = 0$

shows at once that that quantity is a function of x .

(147.) The preceding considerations may easily be extended to the first integrals of equations containing differential coefficients of an order higher than the first.

Let $u = F\left(x, y, \frac{dy}{dx}, \dots, \frac{d^{n-1}y}{dx^{n-1}}, a\right) = 0$, be the first integral of $f\left(x, y, \frac{dy}{dx}, \dots, \frac{d^n y}{dx^n}\right) = 0$, a being the arbitrary constant introduced by the integration. By using the same reasoning as before, it will be obvious that the elimination of a between $u = 0$ and $\frac{du}{da} = 0$, will lead to a first integral of $f\left(x, y, \frac{dy}{dx}, \dots, \frac{d^n y}{dx^n}\right) = 0$ without an arbitrary constant, and which will be a particular solution, if the equation resulting from the elimination of one of the variables between $u = 0$ and $\frac{du}{da} = 0$ give a variable value for a . In the elimination of a between $u = 0$ and $\frac{du}{da} = 0$, several or all the differential coefficients might disappear, and in that case, we should obtain a particular solution of the differential equation, deprived of arbitrary constants and differential coefficients.

(148.) It is known by the general theory of differential equations that a differential equation of the n^{th} order

Integral
Calculus.

$$y + \left(\frac{a}{2} - a^2\right)x^2 - (1 - 2a)x \frac{dy}{dx} - a^2 - \frac{dy^2}{dx^2} = 0,$$

and

$$y - \frac{\left(b + \frac{dy}{dx}\right)}{2}x - \frac{\left(b - \frac{dy}{dx}\right)^2}{x^2} - b^2 = 0.$$

 If we differentiate the first with respect to a , we find

$$\left(\frac{1}{2} - 2a\right)x^2 + 2x \frac{dy}{dx} - 2a = 0,$$

which gives $a = \frac{x^2 + 4x \frac{dy}{dx}}{4(x^2 + 1)}$. This value being substituted in the first equation will give, after reduction, for the particular solution of the differential equation of the second order

$$(1 + x^2)y - \left(x + \frac{x^3}{2}\right) \frac{dy}{dx} - \frac{dy^2}{dx^2} + \frac{x^4}{16} = 0.$$

 If we differentiate now the second equation with respect to b , we find

$$\frac{x}{2} + \frac{2\left(b - \frac{dy}{dx}\right)}{x^2} + 2b = 0,$$

which gives $b = \frac{\frac{4}{dx} \frac{dy}{dx}}{4(1 + x^2)}$, and the substitution of this value gives precisely the same result as the substitution of a in the first.

(149.) When a particular solution of the $(n - 1)^{th}$ order has been found, for a differential equation of the n^{th} order, if the first general integral of that particular solution may be determined, the same process may be applied to it to find a particular solution of the first particular solution; it will then be a differential equation of the $(n - 2)^{th}$ order without any constant, but it will not always satisfy the proposed differential equation of the n^{th} order, and therefore cannot be considered as a particular solution of it. (See *Leçons sur le Calcul des Fonctions*, *Leçon 14me.*)

(150.) The particular solutions may be derived from the general integral by another process.

Let $F(x, y, a) = u = 0$ still represent the general integral of a differential equation of the first order, $f\left(x, y, \frac{dy}{dx}\right) = 0$. If in the general integral we consider a as a function of x and y , we shall get, in differentiating u successively with respect to x and to y ,

$$\frac{du}{dx} + \frac{du}{da} \cdot \frac{da}{dx} = 0, \quad \frac{du}{dy} + \frac{du}{da} \cdot \frac{da}{dy} = 0,$$

and hence

$$\frac{da}{dx} = \frac{du}{dx} \div \frac{du}{da}, \quad \frac{da}{dy} = \frac{du}{dy} \div \frac{du}{da}.$$

But it has been proved that the values of a which correspond to particular solutions, make $\frac{du}{da} = 0$, therefore these same values of a must make $\frac{da}{dx} = \infty$ and $\frac{da}{dy} = \infty$. If, therefore, there exist a particular solution, we shall find it by eliminating the quantity a between the general integral, and either of the equations $\frac{da}{dy} = \infty$, $\frac{da}{dx} = \infty$, derived from the general integral.

Example. The general integral of $x dx + y dy = dy \sqrt{(x^2 + y^2 - a^2)}$ is $x^2 - 2ay - a^2 - b = 0$. Here we have $\frac{da}{dx} = \frac{x}{a - y}$, $\frac{da}{dy} = \frac{a}{a - y}$, and the condition $\frac{da}{dx}$ or $\frac{da}{dy} = \infty$ gives $a - y = 0$, or $a = y$, which value being substituted in the general integral, leads to the particular solution $x^2 + y^2 = b$.

In this example there can be no doubt that the equation $x^2 + y^2 = b$, resulting from the elimination of a , is a particular solution, because the value of a is variable; but generally it will be necessary to determine, as before, by the elimination of x or y between the two equations, if a is not a constant quantity, in which case the equation obtained would only be a particular integral.

(151.) The manner we have just explained to find a particular solution, shows that when the general integral can be resolved with respect to the arbitrary constant a , and that the value of a expressed in terms of x and y , is either a fractional power less than one, of a rational function of x and y , or composed of a rational quantity and such an irrational part, the particular solution may be immediately obtained, by making the quantity raised

to a fractional power equal to zero. This is clearly true because in finding the value of $\frac{da}{dx}$, or $\frac{da}{dy}$, the quantity raised to a fractional power becomes a denominator. In the above example for instance, the value of a , deduced from the general integral, is $-y \pm \sqrt{(y^2 + x^2 - b)}$, and the quantity under the radical sign being equal to zero gives the particular solution $x^2 + y^2 = b$. In the example given (146.) the value of the constant is

$$\frac{yx \pm \sqrt{(y^2 x^2 - (y^2 - n^2)(x^2 - n^2))}}{x^2 - n^2},$$

and gives immediately for the particular solution $y^2 x^2 - (y^2 - n^2)(x^2 - n^2) = 0$, or $x^2 + y^2 = n^2$, as we found before. In this case the value of the constant c has for denominator a function of x , which will remain in the value of $\frac{dc}{dx}$, and consequently by making this denominator equal zero, we may have also a particular

solution; we find thus $x^2 - n^2 = 0$, but it is easy to see that this is only a particular integral corresponding to the value $c = \infty$. In other cases, however, by making the denominator equal to nothing we might get a particular solution.

(152.) Particular solutions have the remarkable property of rendering infinite, the factors by which differential equations ought to be multiplied to become an exact differential.

Let $M dx + N dy = 0$ be the differential equation, and let the general integral be $u = c$, supposing it to be resolved with respect to the constant. If $w = 0$ be a particular solution, it will not satisfy the immediate

differential of $u = c$, in the supposition of c being a constant, that is $\frac{du}{dx} dx + \frac{du}{dy} dy = 0$, since this particular solution corresponds to a variable value of c . Now if z be the factor which renders the proposed differential

equation $M dx + N dy = 0$ an immediate differential, the equation $\frac{du}{dx} dx + \frac{du}{dy} dy = 0$ is identical with

$z(M dx + N dy) = 0$. Therefore the particular solution $w = 0$ does not satisfy this last equation, but it satisfies the proposed differential equation $M dx + N dy$, consequently $w = 0$ must render z infinite.

The differential equation $x dx + y dy = y \sqrt{(x^2 + y^2 - a^2)}$ becomes an immediate differential

$$\frac{x dx + y dy}{\sqrt{(x^2 + y^2 - a^2)}} - dy = 0,$$

when it is multiplied by the factor $\frac{1}{\sqrt{(x^2 + y^2 - a^2)}}$, and the particular solution which we have found to be $x^2 + y^2 - a^2 = 0$ renders this function infinite.

(153.) It may be proved more generally, that if we equal to nothing a function by which multiplying or dividing a differential equation we render it an immediate differential, we have an equation which satisfies the proposed differential equation. This may easily be shown by means of the equation furnished by the condition

of integrability; for if we represent successively by z and $\frac{1}{z}$ the factor corresponding to a differential equation $M dx + N dy = 0$, and if we develop the equations of condition

$$\frac{dMz}{dy} = \frac{dNz}{dx}, \quad \frac{dM \frac{1}{z}}{dy} = \frac{dN \frac{1}{z}}{dx},$$

we get the following equations

$$\begin{aligned} \frac{M dz}{dy} - \frac{N dz}{dx} + z \left(\frac{dM}{dy} - \frac{dN}{dx} \right) &= 0, \\ \frac{M dz}{dy} - \frac{N dz}{dx} + z \left(\frac{dM}{dy} - \frac{dN}{dx} \right) &= 0, \end{aligned}$$

which the supposition of $z = 0$ reduces to $\frac{M dz}{dy} - \frac{N dz}{dx} = 0$; but if we differentiate $z = 0$, we get

$$\frac{dz}{dy} = - \frac{dz}{dx} \cdot \frac{dx}{dy},$$

and this value being substituted in the above equation gives the proposed differential equation $M dx + N dy = 0$, which therefore is satisfied since the value of z satisfies the preceding equations.

It has been proved in the preceding paragraph that every particular solution makes the factor equal to infinity, hence in the first of the two last suppositions the equation $z = 0$, which satisfies the proposed differential equation, cannot be a particular solution, and must be therefore a particular integral. It may be easily verified in observing that if $U = 0$ designate the general integral of $M dx + N dy = 0$, we have

Integral
Calculus.

Part III.

$$Z = \frac{1}{M} \frac{dU}{dx} = \frac{1}{N} \frac{dU}{dy}$$

from which we infer, that if the supposition $z = 0$ does not render M and N infinite, it will give $du = 0$, and consequently u equal to a constant quantity.

In the second case we have $z = M \cdot \frac{1}{\frac{du}{dx}} = N \cdot \frac{1}{\frac{du}{dy}}$, and the supposition $z = 0$ renders the functions $\frac{du}{dx}$ and $\frac{du}{dy}$ infinite, if it do not make M and N equal to nothing; this solution will besides be a particular solution, or a particular integral, according as it will give for u a value constant or variable.

It is necessary, however, to observe, that the equation $\frac{M dz}{dy} - \frac{N dz}{dx} = 0$ is no longer a necessary consequence of the supposition $z = 0$, when that supposition makes the functions $\frac{dM}{dy}$ and $\frac{dN}{dx}$ equal to infinity; but in the case where only one of the two functions M and N is equal to nothing, M for instance, the equation of condition gives $\frac{dz}{dx} = 0$, consequently z contains only y and therefore from $z = 0$ we deduce $y = a$ constant, an equation which clearly satisfies $M dx + N dy = 0$, since already M is equal to nothing.

The relations which exist between particular integrals, particular solutions, and the factors by which differential equations must be multiplied to become immediate differentials, may be useful to discover these factors. We cannot, however, enter into these investigations, and must refer the reader to the Papers of Trembley, in the *Mémoires de l'Académie de Turin*, for the years 1790 and 1791.

(154.) We have supposed hitherto that the general integral of the proposed differential equation was known, but it may also be required to find the particular solution without the help of the general integral. Let us first examine, how we may ascertain if an equation without a constant, satisfying a differential equation, is a particular integral or a particular solution.

Let the value of y derived from the proposed solution be X , and let the value derived from the general integral be represented by V . This last quantity contains necessarily an arbitrary constant, which we shall call c . Now, it is obvious that if the proposed solution be a particular solution, no constant value of c can make V equal to X ; but if it be a particular integral, there is a certain value c' of c which will give $V = X$; hence $V - X$ must be divisible by $c - c'$, and consequently $V - X$ may be represented by $A(c - c')^m$, where A is a quantity which becomes neither infinite nor equal to zero, when $c - c' = 0$, and where $m > 0$. Let $(c - c')^m = h$, then we may assume

$$V - X = V' h + V'' h^2 + \dots \text{ or } V = X + V' h + V'' h^2 + \&c.$$

Let the value of $\frac{dy}{dx}$, derived from the proposed differential equation, be represented by p , the equation

$dy = p dx$ ought to be satisfied by $y = v$, or $y = X + V' h + V'' h^2 + \&c.$ independently of h ; and if we designate this value of y by $X + K$, putting this value for y into p , we may represent the result of the substitution by

$$P + P' K^m + P'' K^n + \&c.$$

where the exponents $m, n, \&c.$ are ascending. They are, moreover, all positive, for p is not infinite when $K = 0$, since the value $y = X$ satisfies the differential equation $dy = p dx$, and gives $dX = P dx$. We have, therefore,

$$d(X + k) = dX + dk = (P + P' k^m + P'' k^n + \&c.) dx,$$

or,

$$dk = (P' k^m + P'' k^n + \&c.) dx.$$

Substituting for k its value, $V' h + V'' h^2 + \&c.$, we obtain

$$h dV' + h^2 dV'' + \&c. = \begin{cases} P' h^m (V' + V'' h^{n-1} + \dots)^m \\ + P'' h^n (V' + V'' h^{n-1} + \dots) \\ + \dots \end{cases}$$

This equation must be satisfied independently of any particular value of x , when $y = X$ is a particular integral; and if this be not possible, we may infer that $y = X$ is a particular solution. Comparing the terms, in both sides of the equation, containing the lowest exponents of h , we find first the equation

$$dV' = P' h^{m-1} V'^m dx,$$

which cannot be satisfied, independently of h , unless $m - 1 = 0$, or $m = 1$. In that supposition it becomes $dV' = P' V' dx$, from which we get $V' = e^{\int P' dx}$.

If $m > 1$, the first term $P' V'^m h^m dx$ of the right side, cannot be compared to the first term $h dV'$ of the left side; but $h dV'$ may disappear by supposing $dV' = 0$, that is V' equal to a constant quantity, if then we suppose $\mu = m$, we find $dV'' = P' dx$, or $V'' = \int P' dx$, and the other terms may be found in a similar way.

When $m < 1$ the two series cannot be identified by any supposition, therefore if m be a proper fraction $y = X$ is a particular solution, and if m be equal to or greater than one, $y = x$ is a particular integral.

Integral
Calculus.

(155.) It is easy to deduce from this investigation the means of discovering the particular solutions of differential equations of the first order, without knowing the general integral. We have proved that if $X + k$ be Part III.

substituted for y in the value of $\frac{dy}{dx}$ derived from the differential equation, $y = X$ being a particular solution, the second term of the developement contains a power of k less than one, consequently the value of $\frac{dp}{dy}$ corresponding to $y = X$, must be infinite. Hence if $\frac{dp}{dy} = \frac{K}{L}$, every particular solution must render $L = 0$, and must therefore be a divisor of it; and reciprocally every divisor of L , which is not at the same time a divisor of K , and which being made equal to nothing will verify the proposed differential equation, will be a particular solution of it.

(156.) This supposes that the differential equation is resolved with respect to the differential coefficient $\frac{dy}{dx}$, but this resolution may be avoided in observing that if $z = 0$ be this differential equation, z is a function of x , y and p ($p = \frac{dy}{dx}$), and gives

$$\frac{dz}{dx} dx + \frac{dz}{dy} dy + \frac{dz}{dp} dp = 0,$$

from which we derive

$$\frac{dp}{dy} = - \frac{\frac{dz}{dy}}{\frac{dz}{dp}}.$$

Hence if the equation $z = 0$ has been prepared in such a manner as to contain neither radical quantities nor denominators, it will be sufficient to make equal to nothing one of the divisors of $\frac{dz}{dp}$ which does not divide $\frac{dz}{dy}$ in order to render $\frac{dp}{dy}$ equal to infinity. If the differential equation $z = 0$ had not been cleared of radicals, the condition may also be satisfied by making equal to nothing one of the factors of $\frac{1}{\frac{dz}{dy}}$. The elimination of p

between the proposed differential equation, and the new equation thus obtained will give the particular solution.

This process would only give the particular solutions in which y enters; those having the form $x = a$ constant, could be obtained by considering in the proposed differential equation x as a function of y .

To give an example of the two preceding methods of discovering the particular solutions. Let

$$y - px - a(1 + p^2) = 0$$

be the proposed differential equation, p being equal to $\frac{dy}{dx}$. We derive from it

$$p = \frac{-x \pm \sqrt{x^2 + 4ay - y^2}}{2a}, \text{ and } \frac{dp}{dy} = \frac{1}{\sqrt{x^2 + 4ay - y^2}}.$$

The denominator of this expression being made equal to nothing gives $x^2 + 4ay - y^2 = 0$, which equation satisfies the differential equation, and is therefore a particular solution of it.

By the second method we shall obtain the same particular solution, without resolving the differential equation with respect to p . Here $z = y - px - a(1 + p^2)$ and $\frac{dz}{dp} = -x - 2ap$. Eliminating p between the proposed differential equation and $x + 2ap = 0$, we find as before $4ay - 4a^2 + x^2 = 0$.

(157.) From what has been already observed on the method of deducing singular solutions from general ones, (151.) it is obvious that whenever the value of p derived from the differential equation is composed of a rational function of x and y and of a power less than one of another rational function of these variables, by making this last function equal to nothing, the conditions $\frac{dp}{dy} = \infty$ will be satisfied, and therefore if the equation thus formed should satisfy the proposed differential equation it will be a particular solution of it. Thus, in the last example, p being equal to $\frac{-x \pm \sqrt{x^2 + 4ay - y^2}}{2a}$, we might have immediately obtained the particular solution by making the quantity under the radical sign equal to nothing.

(158.) When the differential coefficient p enters the proposed differential equation only in the first power, the differential equation has necessarily the form $K + pL = 0$, (K and L being functions of x and y without radicals

Integral
Calculus.

Part III.

and without denominators,) and consequently $\frac{dz}{dp}$ is in that case $= L$. This being made equal to nothing gives

the equation $L = 0$, and the elimination of p between this equation, and the proposed $K + pL = 0$ is no longer necessary, since L does not contain p . But the equation $L = 0$ cannot give a particular solution unless L , or one of the divisors of L , should be a divisor of K . Then, as it has already been stated, that divisor being made equal to nothing is a particular solution, if it cannot be derived from the general integral by giving a particular value to the constant.

(159.) Another consequence of the property which particular solutions possess of making $\frac{dz}{dp} = 0$ is that they render $\frac{dp}{dx}$ or $\frac{d^2p}{dx^2} = 0$, we have

$$\frac{dz}{dp} dp + \frac{dz}{dx} dx + \frac{dz}{dy} dy = 0,$$

from which we get

$$dp = \frac{d^2y}{dx^2} = - \frac{\left(\frac{dz}{dx} dx + \frac{dz}{dy} dy \right)}{\frac{dz}{dp}},$$

a fraction the numerator and denominator of which are both equal to nothing, since for particular solutions we have at the same time

$$\frac{dz}{dp} dp + \frac{dz}{dx} dx + \frac{dz}{dy} dy = 0, \quad \text{and} \quad \frac{dz}{dp} = 0.$$

(160.) It has been already stated that the common divisors of M and N in the differential equation $M dx + N dy = 0$, may be particular solutions. It may be proved, also, that every differential equation may be prepared in such a manner as to make its particular solution a factor of it.

Let $y = X$ be a solution of the differential equation $dy = p dx$, then $dX = P dx$, P being what p becomes when y is changed into X . If we subtract the last equation from the preceding, we find

$$\frac{dy}{dx} - \frac{dX}{dx} = p - P,$$

an equation which becomes identical by the supposition of $y = X$; hence we may suppose $p - P = Q(y - X)^m$, Q being a function which does not become infinite by the supposition of $y = X$, and m being a positive quantity.

We have, thus, $p = P + Q(y - X)^m$; but since the supposition $y = X$ makes $\frac{dp}{dy} = \infty$, m must be less than

one. Let us suppose $y - X = z$, we shall have then $p = P + Qz^m$, or $dy = (P + Qz^m) dx$. We have also $dy = dz + dX$, and hence $dz = Qz^m dx$, a result which may be written in the following manner,

$$z^m (z^{-m} dz - Q dx) = 0. \quad \text{If then we suppose } z = u^{\frac{1}{1-m}}, \text{ we have } z^m = u^{\frac{m}{1-m}}, \quad z^{-m} = u^{\frac{-m}{1-m}}, \text{ and } z^{-m} dz = \frac{du}{1-m},$$

which values being substituted in the equation, give

$$u^{\frac{m}{1-m}} \left(\frac{du}{1-m} - Q dx \right) = 0.$$

This differential equation has for factor $u^{\frac{m}{1-m}} = z = y - X$, that is the particular solution, and when it is divided by $u^{\frac{m}{1-m}}$ it becomes $\frac{du}{1-m} - Q dx = 0$, which is no longer satisfied by the particular solution $y - X = z = 0$.

(161.) The considerations which have led us to the preceding rules to obtain the particular solution of a differential equation of the first order by means of that equation may be extended to any order.

Let $\frac{dy}{dx} = y_1$, $\frac{d^2y}{dx^2} = y_2$, ..., $\frac{d^ny}{dx^n} = y_n$, and let us suppose the proposed differential equation of the n^{th} order to be resolved with respect to the differential coefficient of the $(n-1)^{\text{th}}$ order, and represented by

$$y_{n-1} = f(x, y, y_1, \dots, y_{n-2}, y_n).$$

Let $y_{n-1} = X$ be a differential equation of the $(n-1)^{\text{th}}$ order, without constant, satisfying the preceding, and let it be required to examine whether it is a particular integral or a particular solution of it. Let the general integral be $y_{n-1} = V$. If X be a particular integral, we shall have in using the same reasoning, and the same notation as in (154.)

$$y_{n-1} = X + V' h + V'' h^2 + \&c.$$

Differentiating both sides, we find

$$y_n = \frac{dX}{dx} + \frac{dX}{dy} y_1 + \frac{dX}{dy_1} y_2 + \dots + \frac{dX}{dy_{n-2}} (X + V' h + V'' h^2 + \&c.) + \frac{1}{dx} dV' \cdot h + \frac{1}{dx} dV'' h^2 + \&c.$$

Let X' be equal to the terms which do not contain h , and K the sum of those which are multiplied by the

Integral
Calculus.

powers of that quantity, then $y_n = x + k$, and that value substituted in the proposed differential equation must satisfy it independently of h . The substitution gives Part III.

$$y_{n-1} = x + v' h + v'' h^2 + \&c. = f(x, y, y_1, \dots, y_{n-2}, X') + P' K^m + P'' K^n + \&c.$$

but $X = f(x, y, y_1, \dots, y_{n-1}, X')$ since $y = X$ satisfies the proposed equation, therefore

$$v' h + v'' h^2 + \&c. = P' h^m \left\{ \frac{V' dX}{d y_{n-2}} + \frac{1}{d x} d V' + \left(V'' \frac{dX}{d y_{n-2}} + \frac{1}{d x} d V'' h^{n-1} \right) + \&c. \right\}^m + \&c.$$

Here it is when $m > 1$ that $y = X$ is a particular solution, for in order to complete the particular solution $y_{n-1} = X$, it is necessary that the function V' should not be equal to nothing, and it is precisely what ought to take place if $m > 1$, since the term $V' h$ would be the only one of that form.

In every other case, the value of V' may be determined. If $m = 1$, we have the equation

$$V' = P' \left(V' \frac{dX}{d y_{n-2}} + \frac{1}{d x} d V' \right),$$

from which the quantities $y, y_1, \dots, y_{n-2}$ may be eliminated by means of the general integral of $y_{n-1} = X$, and its differential equations down to the $(n-2)^{th}$ order.

When $m < 1$ the value of V' is determined by means of the equation

$$V' \frac{dX}{d y_{n-2}} + \frac{1}{d x} d V' = 0.$$

Now if $m > 1$ the value of $\frac{d y_{n-1}}{d y_n}$ derived from the proposed equation, and corresponding to the value $y_{n-1} = X$, must be equal to nothing. Hence a criterion by means of which the particular solutions of the $(n-1)^{th}$ order of a differential equation of the n^{th} order may be discovered.

It may happen that the value $y_{n-1} = X$ should render the right side of the proposed equation $y_{n-1} = f(x, y, y_1, y_2, \dots, y_{n-2}, y_n)$ equal to $\frac{0}{0}$. In that case this last equation may be put under the form

$$y_{n-1} = \frac{M(y_n - X')^n}{N(y_n - X')^n}, \text{ and is satisfied in taking } y_n = X'. \text{ This value agrees with } y_{n-1} = X + c \text{ when } X' \text{ does}$$

not contain X , that is to say when X does not contain y_{n-2} . In the contrary case, we find as above

$$x + v' h + \&c. = k^{n-1} (P + P' k + \&c.), \quad P \text{ being } \frac{M}{N},$$

and it is obvious that this equation cannot be satisfied independently of h unless $\mu = \nu$, $P = X$, and unless P' be not equal to nothing, in order that the term $v' h$ should remain. In every other case the equation $y_{n-1} = X$ is a particular solution.

(162.) If the proposed equation is under the form $y_n = p$, p being a function of $y, y_1, \dots, y_{n-1}$. We have then

$$d y_n = \frac{d p}{d x} d x + \frac{d p}{d y} d y + \frac{d p}{d y_1} d y_1 + \dots + \frac{d p}{d y_{n-1}} d y_{n-1},$$

from which

$$\frac{d y_{n-1}}{d y_n} = \frac{1}{\frac{d p}{d y_{n-1}}};$$

and since particular solutions satisfy the equation $\frac{d y_{n-1}}{d y_n} = 0$, they must render the quantity $\frac{d p}{d y_{n-1}}$ infinite. This

in the case where $n = 1$ is precisely the criterion we have found for particular solutions of differential equations of the first order.

(163.) When the differential equation is not resolved, if we represent it by $z = 0$, and differentiate it we find

$$\frac{d z}{d x} d x + \frac{d z}{d y} d y + \dots + \frac{d z}{d y_{n-1}} d y_{n-1} + \frac{d z}{d y_n} d y_n = 0$$

from which

$$\frac{d y_{n-1}}{d y_n} = - \frac{\frac{d z}{d y_n}}{\frac{d z}{d y_{n-1}}};$$

hence it follows that if z be a rational and integral function of y and of its differential coefficients, the particular solution $y_{n-1} = X$ will render equal to nothing the function $\frac{d z}{d y_n}$. If the quantity $\frac{d z}{d y_{n-1}}$ should vanish at the same

time in which case we would have $\frac{d y_{n-1}}{d y_n} = \frac{0}{0}$, we should find the true value of that fraction; and the only

Integral
Calculus.

Part III.

particular solutions would be those factors, which satisfying the proposed differential equation would, at the same time, render the true value of $\frac{dy_{n-1}}{dy_n}$ equal to nothing.

(164.) Let us consider now the case in which the equation without constants which satisfies the proposed differential equation is of the $(n-2)^{th}$ order. Let that equation be $y_{n-2} = X$, and the proposed differential equation by

$$y_{n-2} = f(x, y, y_1, \dots, y_{n-3}, y_{n-1}, y_n).$$

If, then, we represent the general integral by

$$y_{n-2} = X + V'h + V''h^2 + \&c.,$$

differentiate twice, and each time substitute for y_{n-2} its value, we find

$$\left. \begin{aligned} y_{n-1} &= \frac{dX}{dx} + \frac{dX}{dy} y_1 \dots + \frac{dX}{dy_{n-3}} (X + V'h + \&c.) \\ &\quad + \frac{1}{dx} dV'h + \&c. \end{aligned} \right\} = X' + w'h,$$

$$\left. \begin{aligned} y_n &= \frac{dX'}{dx} + \frac{dX'}{dy} y_1 \dots + \frac{dX'}{dy_{n-3}} (X + V'h + \&c.) \\ &\quad + \frac{1}{dx} dw'h. \end{aligned} \right\} = X'' + w'h,$$

X' and X'' being functions independent of h . The substitution of these expressions, in the proposed equation, and its development according to the powers of h , will easily be obtained, when we shall have the development of what becomes $f(x, y, y_1, \dots, y_{n-3}, y_{n-1}, y_n)$, when $y_{n-1} + k$, and $y_n + l$ are substituted for y_{n-1} and y_n . Let us suppose that this development has the following form,

$$f(x, y, y_1, \dots, y_{n-3}, y_{n-1}, y_n) + P'K^m + Q'l^n + \&c.$$

making now $y_{n-1} = x'$, $y_n = X''$, $k = w'h$, $l = w'h$, substituting in the proposed equation and reducing, it will remain

$$v'h + \&c. = P'w'^m h^m + Q'w'^n h^n + \&c.$$

an equation which cannot be satisfied independently of h , when m and n are > 1 , without making $v' = 0$, which shows that in that case no arbitrary constant can be introduced in the equation $y_{n-2} = X$, and therefore in that case it is a particular solution. Hence the two equations,

$$\frac{dy_{n-2}}{dy_{n-1}} = 0, \quad \frac{dy_{n-2}}{dy_n} = 0,$$

must be satisfied as well as the proposed differential equation, if $y_{n-2} = X$ be a particular solution.

By a similar process we would obtain the conditions which must be satisfied in order that an equation of the $(n-3)^{th}$ order should be a particular solution, and generally in order that an equation of the $(n-m)^{th}$ order, without arbitrary constant, should be a particular solution. If the proposed differential equation may be put under the form

$$y_{n-m} = f(x, y, y_1, \dots, y_{n-m-1}, y_{n-m+1}, \dots, y_n)$$

the particular solutions will satisfy the equations

$$\frac{dy_{n-m}}{dy_{n-m+1}} = 0, \frac{dy_{n-m}}{dy_{n-m+2}} = 0 \dots \frac{dy_{n-m}}{dy_{n-1}} = 0, \frac{dy_{n-m}}{dy_n} = 0$$

When the differential equation is not resolved with respect to y_{n-m} , if it be cleared of radicals and denominators, and represented by $z = 0$, the particular solutions of the order $(n-m)^{th}$ must satisfy the following equations,

$$\frac{dz}{dy_n} = 0, \frac{dz}{dy_{n-1}} = 0, \frac{dz}{dy_{n-2}} = 0 \dots \frac{dz}{dy_{n-m+1}} = 0.$$

(165.) The equation $z = 0$ gives

$$\frac{dz}{dx} dx + \frac{dz}{dy} dy + \frac{dz}{dy_1} dy_1 + \dots + \frac{dz}{dy_n} dy_n = 0,$$

and hence

$$dy_n = - \frac{\frac{dz}{dx} dx + \frac{dz}{dy} dy + \dots + \frac{dz}{dy_{n-1}} dy_{n-1}}{\frac{dz}{dy_n} dy_n};$$

therefore every particular solution must give $dy_n = 0$, since the substitution of the values of $y_n, y_{n-1}, \dots, y$, expressed in x , verifying the equation $dz = 0$, independently of its last term $\frac{dz}{dy_n} dy_n$, which the particular solution

Integral Calculus. makes equal to nothing, it is necessary that the remainder of the equation $dz = 0$, that is the numerator of the expression of dy_n should vanish also; hence every particular solution of a differential equation of the n^{th} order must make $\frac{d^{n+1}y}{dx^{n+1}} = 0$. Part III.

We shall take for example of the preceding rules, the following equation of the second order,

$$z = y - xy_1 + \frac{x^2}{2}y_2 - y_1y_2 + xy_2^2 = 0,$$

where as before $y_1 = \frac{dy}{dx}$ and $y_2 = \frac{d^2y}{dx^2}$. We find $\frac{dz}{dy_2} = \frac{x^2}{2} - y_1 + 2xy_2 = 0$; eliminating y_2 between this equation and the proposed we find

$$4xy - 3y_1x^2 - y_2^2 - \frac{x^4}{4} = 0,$$

which satisfies the proposed equation, and is consequently a particular solution of the first order.

This equation admits of no particular solution, containing x and y only, for to obtain it, we should eliminate y_1 and y_2 between $z = 0$, $\frac{dz}{dy_1} = 0$, and $\frac{dz}{dy_2} = 0$, that is between the proposed equation and $\frac{x^2}{2} - y_1 + 2xy_2 = 0$, and $x + y_2 = 0$. The elimination gives $y + \frac{x^3}{2} = 0$, which does not satisfy the proposed equation.

For more details upon the subject of particular solutions we must refer the reader to Lagrange's *Leçons sur le Calcul des Fonctions*; *Journal de l'Ecole Polytechnique*, 12^{me} cahier; *Mémoires de l'Académie des Sciences de Turin*, 1790—1791.

On the Integration of Differential Equations by Series.

(166.) The number of differential equations which can be completely integrated is very small, and, moreover most of the integrals are complicated and transcendental, and generally can be of little use to find the value of one of the variables in terms of the other, even by approximation. It is therefore of great importance to be able to derive from the differential equation the value of one of the variables, in a series of terms functions of the other, and easy to calculate. These series, when they are converging for the given value of the variable contained in the series, will give approximatively the value of the other.

(167.) The method which naturally presents itself to obtain these series is that of indeterminate coefficients. An example will show the manner in which it is employed.

Let the proposed equation be $dy + ydx = gx^m dx$, and assume

$$y = Ax^a + Bx^{a+1} + Cx^{a+2} + \&c.$$

We are to determine a , A , B , C , &c., by the condition that this value being substituted in the differential equation will satisfy it. The substitution gives

$$\left. \begin{aligned} aAx^{a-1} + (a+1)Bx^a + (a+2)Cx^{a+1} + (a+3)Dx^{a+2} + \&c. \\ -gx^m + Ax^a + Bx^{a+1} + Cx^{a+2} + \&c. \end{aligned} \right\} = 0;$$

and hence we find

$$a = m + 1, \quad A = \frac{g}{a}, \quad B = \frac{-g}{a(a+1)}, \quad C = \frac{+g}{a(a+1)(a+2)}, \quad D = \frac{-g}{a(a+1)(a+2)(a+3)}, \quad \&c.;$$

and, consequently,

$$y = g \left\{ \frac{x^{m+1}}{m+1} - \frac{x^{m+2}}{(m+1)(m+2)} + \frac{x^{m+3}}{(m+1)(m+2)(m+3)} - \&c. \right\}.$$

This value is not the general integral since it does not contain an arbitrary constant. But by a little modification of the same method the general integral may be obtained. For we shall suppose that to $x = a$ corresponds the value $y = b$, and we shall substitute in the differential equation $a + t$ for x , and $b + u$ for y , u being supposed to become equal to nothing when $t = 0$. We may therefore assume

$$u = At^s + Bt^{s+1} + Ct^{s+2} + \&c.;$$

substituting this value in the differential equation which becomes

$$du + (b + u)dt = g(a + t)^m dt,$$

we shall find

$$a = 1, \quad A = ga^m - b, \quad B = gm a^{m-1} - ga^m + b, \quad C = gm(m-1)a^{m-2} - gm a^{m-1} + ga^m - b, \quad \&c.$$

The equation $dy + xdy - mydx = 0$, treated in the same manner, leads to the following value of y .

Integral Calculus. $y = b \left\{ 1 + \frac{m(x-a)}{a+1} + \frac{m(m-1)}{1 \cdot 2} \frac{(x-a)^2}{(a+1)^2} + \&c. \right\} = b \left\{ 1 + \frac{x-a}{a+1} \right\}^m = \frac{b}{(a+1)^m} (1+x)^m = A(1+x)^m$; Part III.

a series which therefore agrees with the integral obtained by the separation of the variables in the differential equation.

(168.) We shall take for another example the equation $d^2 y + a y x^{m-2} dx = 0$, and we shall assume

$$y = A x^a + B x^{a+\delta} + c x^{a+2\delta} + \&c.;$$

substituting the value of y and $d^2 y$ in the equation, we find, by a comparison of the terms of the result, that we must make $a = 0$ or $a = 1$, and also $\delta = m$: from these two hypotheses we deduce two series for y , each of which contains an arbitrary constant; for in either hypothesis the value of y remains indeterminate, and consequently, being added together, gives the general integral. We find thus

$$y = A \left\{ 1 - \frac{a x^m}{(m-1)m} + \frac{a^2 x^{2m}}{1 \cdot 2 (m-1)(2m-1)m^2} - \frac{a^3 x^{3m}}{1 \cdot 2 \cdot 3 (m-1)(2m-1)(3m-1)m^3} + \&c. \right\} \\ + A' \left\{ x - \frac{a x^{m+1}}{(m+1)m} + \frac{a^2 x^{2m+1}}{1 \cdot 2 (m+1)(2m+1)m^2} - \frac{a^3 x^{3m+1}}{1 \cdot 2 \cdot 3 (m+1)(2m+1)(3m+1)m^3} + \&c. \right\}$$

These series cannot be used for every value of m ; they both fail when $m = 0$; the first when $m = 1$, and the second when $m = -1$, or more generally, i being an integer, the first when $m = \frac{1}{i}$, and the second when $m = -\frac{1}{i}$. We cannot give here this interesting discussion, and must refer the reader to the VIIth Chapter of

the IIId volume of Euler's *Integral Calculus*, or, after him, to Lacroix's *Integral Calculus*, in 4to., or to the *Collection of Examples of the Differential and Integral Calculus* by G. Peacock.

(169.) Another series may be derived from Taylor's Theorem. If we suppose the differential equation resolved with respect to the differential coefficient of the highest order, if we have, for instance,

$$\frac{d^n y}{dx^n} = f\left(x, y, \frac{dy}{dx}, \frac{d^2 y}{dx^2}, \dots, \frac{d^{n-1} y}{dx^{n-1}}\right),$$

it is obvious we shall find

$$y = A + A_1 \frac{(x-a)}{1} + A_2 \frac{(x-a)^2}{1 \cdot 2} + \dots + f(a, A, A_1, A_2, \dots, A_{n-1}) \frac{(x-a)^n}{1 \cdot 2 \cdot 3 \dots n} + \&c.,$$

where $A, A_1, A_2, \dots, A_{n-1}$ represent the values of $y, \frac{dy}{dx}, \frac{d^2 y}{dx^2}, \&c.$ when $x = a$ and are considered as arbitrary constants.

Let us take for example the differential equation $\frac{d^2 y}{dx^2} + \frac{y}{ex} = 0$, and let b and c be the values of y and $\frac{dy}{dx}$ corresponding to $x = a$. We shall have for $x = a$

$$\frac{d^2 y}{dx^2} = -\frac{b}{ea}, \quad \frac{d^3 y}{dx^3} = \frac{b-ac}{ea^2}, \quad \&c.$$

consequently

$$y = b + c \frac{(x-a)}{1} - \frac{b}{ea} \frac{(x-a)^2}{1 \cdot 2} + \frac{b-ac}{ea^2} \frac{(x-a)^3}{1 \cdot 2 \cdot 3} + \&c.$$

If $(x-a)$ be a small quantity, and if none of the differential coefficients as far as the series is carried becomes infinite, this series will easily give the value of y . If the value of x , corresponding to which the value of y is required, were much greater than a , we might suppose $x-a$ equal to nh , so that by taking n a large number we may always suppose h to be a very small quantity; then we might first calculate the value of y corresponding to $a+h$, and then, by means of it, the value of y corresponding to $x = a+2h$, and so on, by successive substitutions, we might find the required value. It must be observed, however, that this method frequently fails in giving the approximation with sufficient accuracy, in consequence of the accumulation of errors introduced after each operation.

(170.) Mr. Kramp has proposed another method. He first observes that if the general integral were known and the value of y expressed in function of x , it would always be possible, whatever be the nature of this function, to represent its value corresponding to any particular value a of x , or to any value differing but little from a by an expression of the form $A + Bx + Cx^2 + \dots + Rx^m$, and indeed that the difference between the value of y derived from the general integral, and the value of y derived from the equation $y = A + Bx + Cx^2 + \dots + Rx^m$, might be decreased at will by taking m sufficiently great. Let us see, now, if the values of the coefficients $A, B, C, \dots, R$, cannot be determined without the general integral. They must first satisfy the conditions relative to the determination of constants, which, in supposing the differential equation of the n^{th} order, will give n equations between $A, B, C, \dots, R$. It will remain only to find $m-n+1$ others.

Integral
Calculus.From the assumed value of y , we derive

$$\frac{dy}{dx} = B + 2Cx + 3Dx^2 + \dots + mRx^{m-1}$$

$$\frac{d^2y}{dx^2} = 2C + 6Dx + 12Ex^2 + \dots + m(m-1)Rx^{m-2}$$

.....
.....

These values must satisfy the differential equation, which I represent by $\phi\left(x, y, \frac{dy}{dx}, \frac{d^2y}{dx^2}, \dots, \frac{d^ny}{dx^n}\right) = 0$. The

result of their substitution will be a certain function of $x, A, B, C, \dots, R$, which would be identically, or very nearly, equal to nothing when a , or values little differing from a , are substituted for x . If, therefore, we express that it is equal to nothing for $m+n-1$ such values of x , we shall get between the coefficients $A, B, C, \dots, R$, the necessary number of equations to complete their determination.

As the number m is an arbitrary number, we may always take it so that $m+n-1$ shall be an odd number $2p+1$; then it will be sufficient to substitute successively for $x, a, a \pm z, a \pm 2z, \dots, a \pm pz$, z being a very small quantity; or we may first substitute, in the proposed equation, $a+zx$ for x , and then we shall have only to make, in the equation of condition, $x=0, x=\pm 1, x=\pm 2, \dots, x=\pm p$.

If the proposed equation $\phi\left(x, y, \frac{dy}{dx}, \frac{d^2y}{dx^2}, \dots, \frac{d^ny}{dx^n}\right) = 0$ contain the differential coefficients in a degree

higher than the first, the substitutions of the values of $\frac{dy}{dx}, \frac{d^2y}{dx^2}$, &c., derived from the assumed value of y , would

be laborious, and moreover the coefficients A, B, C would enter the equation in a degree higher than the first, and the equations, by means of which their values are to be found, would be difficult to resolve. To avoid this, the best way would be to differentiate the proposed equation a sufficient number of times, and to combine the differential equations together so as to obtain the simplest possible differential equation. It would become then necessary to add to the conditions already established for the determination of the constants, a number of others precisely equal to the excess of the order of differentiation of the new equation over the order of the proposed equation.

The same process of differentiating the proposed equation may be used in case it should contain transcendental functions, in order to obtain an algebraical equation.

We shall apply this method to a very simple example, but which will be sufficient to show the particular advantages of this method.

Let the equation be $x \frac{dy}{dx} = 1$; it is required to find the value of y corresponding to a given value a of x , supposing besides that the arbitrary constant, which ought to enter into the general integral, is to be determined by the condition that $y=0$ when $x=1$.

If we change x into $a+zx$, the proposed equation becomes $(a+zx) \frac{dy}{dx} - z = 0$, and the constant must be such that when $a+zx=1$, or $x=\frac{1-a}{z}$, y shall be equal to nothing. Let us first assume $y=A+Bx$,

we shall have $\frac{dy}{dx}=B$, and these values being substituted give $(a+zx)B - z = 0$; making $x=0$ we have

$aB - z = 0$; the condition relative to the constant gives, besides, $0 = A + \frac{(1-a)}{z}B$; eliminating b between

these two equations, from which z disappears, we shall find $A = \frac{a-1}{a}$, and $B = \frac{z}{a}$, therefore $y = \frac{a-1}{a} + \frac{Bz}{a}$;

and if we suppose $z=0$, simply $y = \frac{a-1}{a}$, or generally the value of y corresponding to any value x is equal to $\frac{x-1}{x}$. In this example, we may easily compare the exact value with the approximate one, for the differential

equation obviously gives $y = lx$, therefore we have approximatively $lx = \frac{x-1}{x}$. This formula is exact for

$x=0$ and for $x=1$, and for numbers very nearly equal to one it is sufficiently accurate.

To have a greater approximation, we shall assume

$$y = A + Bx + Cx^2 + Dy^3, \text{ then } \frac{dy}{dx} = B + 2Cx + 3Dx^2,$$

and these values being substituted, give

$$(a+zx)(B+2Cx+3Dx^2) - z = 0, \text{ or } (aB-z) + (Bz+2aC)x + (2Cz+3aD)x^2 + 3Dzx^3 = 0,$$

Integral
Calculus.

 and substituting successively for x , in that equation, the values $-1, 0, +1$, we find

$$0 = (aB - z) - (Bz + 2aC) + (2Cz + 3aD) + 3Dz,$$

$$0 = aB - z, \quad 0 = (aB - z) + (Bz + 2aC) + (2Cz + 3aD) + 3Dz,$$

from which we derive

$$B = +\frac{z}{a}, \quad C = -\frac{z^2}{2(a^2 - z^2)}, \quad D = +\frac{z^3}{3a(a^2 - z^2)}.$$

But the condition relative to the constant gives

$$A = \frac{(a-1)}{z} B - \frac{(a-1)^2}{z^2} C + \frac{(a-1)^3}{z^3} D;$$

 substituting for B, C, D their values, we shall find

$$A = \frac{a-1}{a} + \frac{(a-1)^2}{2(a^2 - z^2)} + \frac{(a-1)^3}{3a(a^2 - z^2)};$$

 and finally, in supposing $z = 0$, and changing a into x ,

$$y = lx = \frac{x-1}{x} + \frac{(x-1)^2}{2x^2} + \frac{(x-1)^3}{3x^3};$$

 a formula more exact than the preceding, but only for values of x differing but little from one

 In the same manner, if we assume $y = A + Bx + Cx^2 + Dx^3 + Ex^4 + Fx^5$, we shall find

$$lx = \frac{x-1}{x} + \frac{(x-1)^2}{2x^2} + \frac{(x-1)^3}{3x^3} + \frac{(x-1)^4}{4x^4} + \frac{(x-1)^5}{5x^5} +$$

 It is not necessary to carry the calculation any further to be led to suppose that the exact value of y would be

$$y = lx = \frac{x-1}{x} + \frac{1}{2} \left(\frac{x-1}{x} \right)^2 + \frac{1}{3} \left(\frac{x-1}{x} \right)^3 + \frac{1}{4} \left(\frac{x-1}{x} \right)^4 + \frac{1}{5} \left(\frac{x-1}{x} \right)^5 + \frac{1}{6} \left(\frac{x-1}{x} \right)^6 + \&c.,$$

a formula which is the known developement of the logarithm.

 For more details on this method see *Annales de Mathématiques de Gergonne*, vol. x. and xi.

 (171.) The value of y may also be obtained under the form of a continued fraction. Let the differential

 equation be $P + Qy + Ry^2 + S \frac{dy}{dx} = 0$, P, Q, R, S being any function whatever of x , we shall assume

$$y = \frac{Ax^a}{1 + Bx^b} \cdot \frac{1 + Cx^c}{1 + Dx^d} \cdot \frac{1 + Ex^e}{1 + \dots}$$

in which expression both the exponents and coefficients are indeterminate. Let

$$y''' = \frac{Dx^d}{1 + \&c.}, \quad y'' = \frac{Cx^c}{1 + y'''}, \quad y' = \frac{Bx^b}{1 + y''}, \quad \text{and } y = \frac{Ax^a}{1 + y'}.$$

 Let us suppose $Ax^a = X$, $Bx^b = X'$, $Cx^c = X''$, we shall have

$$y = \frac{X}{1 + y'}, \quad y' = \frac{X'}{1 + y''}, \quad y'' = \frac{X''}{1 + y'''} \&c.$$

 If then we substitute $\frac{X}{1 + y'}$ instead of y in the proposed equation, we shall obtain a result of the following form,

$$P' + Q'y' + R'y'^2 + S' \frac{dy'}{dx} = 0,$$

 in which $P' = P + QX + RX^2 + S \frac{dX}{dx}$, $Q' = 2P + QX + S \frac{dX}{dx}$, $R' = P$, $S' = -SX$.

 If now we put for y' its value $\frac{X'}{1 + y''}$, we shall have a result which shall be deduced from the preceding in the same manner as it was itself derived from the proposed equation, and therefore if we represent it by

$$P'' + Q''y'' + R''y''^2 + S'' \frac{dy''}{dx} = 0,$$

we shall have

$$P'' = P' + Q'X' + R'X'^2 + S' \frac{dX'}{dx}, \quad Q'' = 2P' + Q'X' + S' \frac{dX'}{dx}, \quad R'' = P', \quad S'' = -S'X'$$

We could obtain in the same manner the result of the substitution of $\frac{C x^\gamma}{1 + y''}$ for y'' , and so on for all the others.

Now to determine the value of X or $A x^a$, we shall first neglect y' , and therefore we shall simply substitute $A x^a$ and $a A x^{a-1}$ for y and $d y$ in the proposed equation, and determine A and a by the condition that the result of that substitution is an identical equation. This value of X once determined, we shall know the coefficients of

the equation resulting from the substitution of $\frac{X}{1 + y}$ for y , in the proposed equation; and since the value of y' is

reduced to X' when y'' is neglected, we shall be able to determine, by means of this transformed equation, the value of X' , in the same manner as we have determined the value of X by means of the proposed equation; thus, we shall find successively the terms of the continued fraction. If one of the quantities $P', P'', P''', \&c.$ which form the first term of the transformed equations, should become nothing, the continued fraction would have a limited number of terms

If we suppose, for instance, that $P''' = 0$, then the third transformed will be $Q''' y''' + R''' y''^2 + S''' \frac{d y''}{d x} = 0$,

which will be satisfied by $y''' = 0$. It is true that this value of y''' is only a particular solution or a particular integral of the preceding equation; but in this case the general integral or complete value of y''' could be

obtained, for by making $y''' = \frac{1}{z}$ the equation is transformed into $Q''' z + R''' - S''' \frac{d z}{d x} = 0$, which can be integrated.

We shall apply this general method to the following example. Let the differential equation be

$$m y + (1 + x) \frac{d y}{d x} = 0.$$

Let us first substitute $A x^a$ for y , we shall find $(m A + a A) x^a + a A x^{a-1} = 0$, or $(m + a) x + a = 0$. Neglecting as a first approximation the term multiplied by x , we find $a = 0$, and consequently A remains indeterminate, and will be the arbitrary constant of the integral. We have, therefore, in this case $X = A$, $P = 0$, $Q = m$, $R = 0$, $S = 1 + x$, and the first transformed equation will be

$$m A + m A y' - (1 + x) A \frac{d y'}{d x} = 0, \text{ or } m + m y' - (1 + x) \frac{d y'}{d x} = 0.$$

If we change now y' into $B x^b$, and $d y'$ into $\beta B x^{b-1} d x$, we find

$$m + m B x^b - \beta B x^{b-1} - \beta B x^b = 0,$$

an equation which is satisfied by making $\beta = 1$ and $B = m$, therefore $X' = m x$; and hence for the second transformed equation

$$(m - 1) x + (1 + (m - 1) x) y'' + y'^2 + (1 + x) x \frac{d y''}{d x} = 0,$$

putting $C x^\gamma$ for y'' , and $\gamma C x^{\gamma-1} d x$, we shall find $\gamma = 1$ or $\gamma = 0$; but the first of these values must be taken, for the exponent of x in the numerator of each of the fractions which follows $\frac{A x^a}{1}$ must be greater than one, since

all these fractions must vanish at the same time as x . We find then $C = -\frac{m-1}{2}$, and $X'' = -\frac{(m-1)x}{1 \cdot 2}$

These operations being carried as far as the sixth transformation, we shall find

$$X''' = \frac{(m+1)x}{3 \cdot 2}, X^{iv} = -\frac{(m-2)x}{3 \cdot 2}, X^v = \frac{(m+2)x}{5 \cdot 2}, X^{vi} = -\frac{(m-3)x}{5 \cdot 2}, \text{ and therefore}$$

$$y = \frac{A}{1 + \frac{m x}{1 - \frac{(m-1)x}{1 - \frac{(m+1)x}{1 - \frac{(m-2)x}{1 - \frac{(m+2)x}{1 - \frac{(m-3)x}{5 \cdot 2}}}}}}}$$

The proposed differential equation is easily integrated, and gives $y = C (1 + x)^{-m}$. When $x = 0$ this value of

Integral
Calculus

y is reduced to $y = C$, and for the same hypothesis, the value of y expressed by a continued fraction is reduced to A , therefore $A = C$, and we shall have consequently $(1+x)^{-m}$ equal to the above continued fraction, after having substituted 1 for A , or again $(1+x)^m$ equal to the denominator of A , carried indefinitely, if m be a fraction, or down to the numerator which becomes equal to nothing, if m be an integer. It is easy to derive from this expression the values of $l(1+x)$ and e^x , under the form of continued fractions. They may also be

found by integrating in the same manner the equations $1 - (1+x) \frac{dy}{dx} = 0$, $y - \frac{dy}{dx} = 0$

They are

$$l(1+x) = \frac{x}{1 + \frac{1}{1} \cdot \frac{x}{2}} \\ \frac{1}{1 + \frac{1}{3} \cdot \frac{x}{2}} \\ \frac{2}{1 + \frac{2}{3} \cdot \frac{x}{2}} \\ \frac{2}{1 + \frac{2}{5} \cdot \frac{x}{2}} \\ \frac{3}{1 + \frac{3}{5} \cdot \frac{x}{2}} \\ 1 + \&c$$

$$e^x = 1 + \frac{x}{1 - \frac{1}{1} \cdot \frac{x}{2}} \\ \frac{1}{1 + \frac{1}{3} \cdot \frac{x}{2}} \\ \frac{1}{1 - \frac{1}{3} \cdot \frac{x}{2}} \\ \frac{1}{1 + \frac{1}{5} \cdot \frac{x}{2}} \\ \frac{1}{1 - \frac{1}{5} \cdot \frac{x}{2}} \\ 1 + \&c$$

(172.) Another process to integrate by series differential equations is founded upon Newton's method of successive substitutions combined with the integration of differential equations of the first degree. Let the proposed

equation be $\frac{d^2 y}{dx^2} + y + a y^2 = b$, in which a is supposed to be a very small quantity, and assume

$$y = Y + a Y' + a^2 Y'' + a^3 Y''' + \&c. \dots Y, Y', Y'', Y''', \&c.$$

being unknown functions of x . This value being substituted in the proposed differential equation gives

$$\frac{d^2 y}{dx^2} + Y - b + a \left(\frac{d^2 Y'}{dx^2} + Y' + Y^2 \right) + a \left(\frac{d^2 Y''}{dx^2} + Y'' + 2 Y Y' \right) \\ + a^2 \left(\frac{d^2 Y'''}{dx^2} + Y''' + Y'^2 + 2 Y Y'' \right) + \&c. \dots = 0.$$

Making equal to nothing the coefficient of each power of a , we find as many differential equations of the second order and first degree as is necessary to find the values of all the quantities $Y, Y', Y'', \&c.$ These equations are

$$\frac{d^2 y}{dx^2} + Y = b, \quad \frac{d^2 Y'}{dx^2} + Y' = -Y^2, \quad \frac{d^2 Y''}{dx^2} + Y'' = -2 Y Y',$$

$$\frac{d^2 Y'''}{dx^2} + Y''' = -Y'^2 - 2 Y Y'', \&c.$$

The first will give the value of y , which will be substituted in the second in order to obtain that of y' , and so on. These equations may be integrated; and the values derived from the three first, are

$$Y = b + p \cos x + q \sin x$$

$$Y' = -\frac{1}{2}(2b^2 + p^2 + q^2) + b q x \cos x + \frac{1}{6}(p^2 - q^2) \cos 2x - b p x \sin x + \frac{1}{3} p q \sin 2x$$

$$Y'' = b(2b^2 + p^2 + q^2) - \left[\frac{1}{12} q (18b^2 + 5p^2 + 5q^2) x + \frac{1}{2} p b^2 x^2 \right] \cos x \\ + \left[\frac{1}{12} p (18b^2 + 5p^2 + 5q^2) x - \frac{1}{2} q b^2 x^2 \right] \sin x \\ - \left[\frac{1}{3} b (p^2 - q^2) - \frac{2}{3} b p q x \right] \cos 2x + \frac{1}{48} p (p^2 - 3q^2) \cos 3x \\ - \left[\frac{1}{3} b (p^2 - q^2) + \frac{2}{3} b p q x \right] \sin 2x + \frac{1}{48} q (3p^2 - q^2) \sin 3x$$

which being substituted in the assumed value of y , will give the approximate value of this quantity by neglecting only the powers of a higher than the second. The arbitrary constants introduced by the integration of the equations which give the values of Y' and Y'' are left out, because there are already two contained in the value of Y .

(173.) It is obvious that the same method may be applied to the equations of the first degree, having the form

Integral
Calculus.

$$\frac{d^n y}{d x^n} + a \frac{d^{n-1} y}{d x^{n-1}} + b \frac{d^{n-2} y}{d x^{n-2}} + \dots + h y = R + a S,$$

$a, b, \dots, h$ being constant coefficients, R a function of x alone, S a function of x and y , and a a very small quantity. We would assume as before $y = Y + a Y' + a^2 Y'' + \&c.$ substituting this value, and making the quantities which multiply each power of y separately equal to nothing, we shall get the following equations,

$$\frac{d^n Y}{d x^n} + a \frac{d^{n-1} Y}{d x^{n-1}} + b \frac{d^{n-2} Y}{d x^{n-2}} + \dots + h Y = R,$$

$$\frac{d^n Y'}{d x^n} + a \frac{d^{n-1} Y'}{d x^{n-1}} + b \frac{d^{n-2} Y'}{d x^{n-2}} + \dots + h Y' = S',$$

$$\frac{d^n Y''}{d x^n} + a \frac{d^{n-1} Y''}{d x^{n-1}} + b \frac{d^{n-2} Y''}{d x^{n-2}} + \dots + h Y'' = S'',$$

&c.

(174.) If we had several simultaneous differential equations of the same form, the same method might be used. Let us suppose, for instance, we had the three differential equations

$$\frac{d^2 x}{d t^2} + a^2 x = R + a S \quad \frac{d^2 y}{d t^2} + a^2 y = R_1 + a S_1, \quad \frac{d^2 z}{d t^2} + a^2 z = R_2 + a S_2,$$

in which R, R_1, R_2 are functions of t alone, S, S_1, S_2 functions where the variables t, x, y , and z are mixed, and a a very small quantity. We shall assume

$$x = X + a X' + a^2 X'' + \&c., \quad y = Y + a Y' + a^2 Y'' + \&c., \quad z = Z + a Z' + a^2 Z'' + \&c.,$$

and if we designate by

$$a S' + a^2 S'' + \&c., \quad a S_1' + a^2 S_1'' + \&c., \quad a S_2' + a^2 S_2'' + \&c.$$

what the quantities $a S, a S_1, a S_2$, become by this supposition, we shall find, in operating as before, that the quantities $X, Y, Z, X', Y', Z', \&c.$ are given by the equations

$$\frac{d^2 X}{d t^2} + a^2 X = R, \quad \frac{d^2 Y}{d t^2} + a^2 Y = R_1, \quad \frac{d^2 Z}{d t^2} + a^2 Z = R_2,$$

$$\frac{d^2 X'}{d t^2} + a^2 X' = S', \quad \frac{d^2 Y'}{d t^2} + a^2 Y' = S_1', \quad \frac{d^2 Z'}{d t^2} + a^2 Z' = S_2',$$

&c.

The functions S', S_1', S_2' , depend only on the variable t and on the functions $X, Y, Z, \&c.$, and consequently the integration of the equations which form the first line will lead to the integration of all the others.

(175.) Another method of integration is founded on the variation of arbitrary constants. Let $y = \phi(x, c_1, c_2, \dots, c_n)$

be the general integral of $\frac{d^n y}{d x^n} + U = 0$. This integral may easily be extended to $\frac{d^n y}{d x^n} + U = a V$, in con-

sidering the constants $c_1, c_2, \dots, c_n$ as functions of the variables. These quantities being n in number they may be chosen so as to satisfy, besides the proposed equation, $n - 1$ other conditions, so, for instance, as to make the values of the $(n - 1)$ first differential coefficients of y derived from the general integral, the same as if $c_1, c_2, \dots, c_n$ were constants. These conditions will give the following equations,

$$\frac{d y}{d c_1} d c_1 + \frac{d y}{d c_2} d c_2 + \dots + \frac{d y}{d c_n} d c_n = 0$$

$$\frac{d^2 y}{d x d c_1} d c_1 + \frac{d^2 y}{d x d c_2} d c_2 + \dots + \frac{d^2 y}{d x d c_n} d c_n = 0$$

$$\dots \dots \dots$$

$$\frac{d^{n-1} y}{d x^{n-2} d c_1} d c_1 + \frac{d^{n-1} y}{d x^{n-2} d c_2} d c_2 + \dots + \frac{d^{n-1} y}{d x^{n-2} d c_n} d c_n = 0.$$

In this manner the functions U and V , which in the most general case can only contain $x, y, \frac{d y}{d x}, \dots, \frac{d^{n-1} y}{d x^{n-1}}$,

will remain the same, and since when the quantities $c_1, c_2, \dots, c_n$ are not supposed to be variable we have

$$\frac{d^n y}{d x^n} + U = 0, \text{ it will remain simply after the substitution in the equation } \frac{d^n y}{d x^n} + U = a U,$$

$$\frac{d^n y}{d x^{n-1} d c_1} d c_1 + \frac{d^n y}{d x^{n-1} d c_2} d c_2 + \dots + \frac{d^n y}{d x^{n-1} d c_n} d c_n = a U d x.$$

This equation with the $(n - 1)$ preceding will give the values of $d c_1, d c_2, \dots, d c_n$. They will be of the form
 $d c_1 = a A_1 V d x, \quad d c_2 = a A_2 V d x, \dots, d c_n = a A_n V d x,$

Integral Calculus. $A_1, A_2, \dots, A_n$ containing as well as V , besides the variable x , the quantities $c_1, c_2, \dots, c_n$; but since these last quantities are constant when $a = 0$, we may suppose that their actual values are developed according to the powers of a in the following form, Part III.

$$c_1 = C_1 + a z_1 + a^2 z_1' + \&c.$$

$$c_2 = C_2 + a z_2 + a^2 z_2' + \&c.$$

$$\dots\dots\dots$$

$$c_n = C_n + a z_n + a^2 z_n' + \&c.$$

$c_1, c_2, \dots, c_n$ being constant quantities. Substituting these values in the preceding expressions of $d c_1, d c_2, \dots, d c_n$, and developing the right sides according to the powers of a , we shall obtain results of the following form,

$$a d z_1 + a^2 d z_1' + \&c. = (a p_1 + a^2 p_1' + \&c.) d x,$$

$$a d z_2 + a^2 d z_2' + \&c. = (a p_2 + a^2 p_2' + \&c.) d x,$$

$$\dots\dots\dots$$

$$a d z_n + a^2 d z_n' + \&c. = (a p_n + a^2 p_n' + \&c.) d x.$$

It is obvious that $p_1, p_2, \&c. p_n$, will only contain the variable x , and the constants $c_1, c_2, \dots, c_n$, consequently that the values

$$d z_1 = p_1 d x, d z_2 = p_2 d x, \dots, d z_n = p_n d x,$$

which are the first approximations, are the same as those which would have been obtained in considering in the equations

$$d c_1 = a A_1 V d x, d c_2 = a A_2 V d x, \dots, d c_n = a A_n V d x,$$

the quantities $c_1, c_2, \dots, c_n$ as constant, in the right sides.

The second approximation will depend on the equations

$$d z_1' = p_1' d x, d z_2' = p_2' d x, \dots, d z_n' = p_n' d x,$$

in the right sides of which, the only quantities which will enter will be the $z_1, z_2, \&c.$ determined by the first approximation. (See *Mémoires de l'Académie de Berlin*, 1781; *Mémoires de l'Institut, pour les Années 1808 et 1809*; *Journal de l'Ecole Polytechnique*, 15me Cahier; *Mécanique Analytique de Lagrange*, tome premier, seconde partie, cinquième section.)

Integration of Differential Equations containing several variables.

(176.) The rules to find a function of several variables when its complete differential, or one of its partial differential coefficients, is explicitly given, have been stated before. We shall now consider the case in which it is only relations expressed by means of equations, between the variables, and all, or some of the partial differential coefficients that are given, and in which it is the relations between the independent variables, and the variables which are functions of them, that are to be determined.

(177.) The simplest case is when the given equation contains all the partial differential coefficients, and each of them in the first power. It is then called a *total differential equation of the first order*. If it contains three variables, it will be of the form

$$P d x + Q d y + R d z = 0,$$

and if the left side of this equation be the exact differential of a function of three variables, the integral will be immediately obtained by the rules previously given, and this integral being made equal to nothing will give the required relation between x, y, z .

(178.) When the equation $P d x + Q d y + R d z = 0$ is not the immediate differential of a function of three variables, that is when the quantity $P d x + Q d y + R d z$ does not satisfy the conditions of integrability, it is sometimes possible to render it the immediate differential of a function of three variables by multiplying it by a factor. Let μ be this factor, and let us suppose that $\mu P d x + \mu Q d y + \mu R d z$ is an exact differential, we shall have then

$$\frac{d \mu R}{d y} = \frac{d \mu Q}{d z}, \quad \frac{d \mu R}{d x} = \frac{d \mu P}{d z}, \quad \frac{d \mu Q}{d x} = \frac{d \mu P}{d y}.$$

These equations being developed, give

$$\mu \left(\frac{d R}{d y} - \frac{d Q}{d z} \right) + R \frac{d \mu}{d y} - Q \frac{d \mu}{d z} = 0.$$

$$\mu \left(\frac{d R}{d x} - \frac{d P}{d z} \right) + R \frac{d \mu}{d x} - P \frac{d \mu}{d z} = 0.$$

$$\mu \left(\frac{d Q}{d x} - \frac{d P}{d y} \right) + Q \frac{d \mu}{d x} - P \frac{d \mu}{d y} = 0.$$

If we multiply the first by P , the second by $-Q$, and the third by R , and if we add the products, the quantity μ will be eliminated, and we find the equation

$$R\left(\frac{dP}{dy} - \frac{dQ}{dx}\right) + Q\left(\frac{dR}{dx} - \frac{dP}{dz}\right) + P\left(\frac{dQ}{dz} - \frac{dR}{dy}\right) = 0.$$

If the coefficients P, Q, R of the proposed equation cannot satisfy it, then it is impossible to find a factor μ which will render it an exact differential.

(179.) When the above condition is fulfilled, the integration of the proposed differential equation depends upon the integration of differential equations of two variables.

To prove it, let us suppose in the proposed equation $P dx + Q dy + R dz = 0$, z constant, it is then reduced to $P dx + Q dy = 0$, and if, in the same hypothesis, μ be the factor by which $P dx + Q dy$ ought to be multiplied to become an exact differential, if $U = \int \mu (P dx + Q dy)$, the integral of the equation $P dx + Q dy = 0$ would be $U = C$, C being an arbitrary constant. Now let us see if we could not determine a function of z , such as to make $U = \phi(z)$ the integral of $P dx + Q dy + R dz = 0$. If we differentiate $u = \phi(z)$, in considering x, y and z as variable quantities, we find

$$\mu (P dx + Q dy) + \frac{dU}{dz} dz = \frac{d\phi(z)}{dz} dz.$$

$$\text{But } \mu (P dx + Q dy) = -\mu R dz, \text{ hence } -\mu R dz + \frac{dU}{dz} dz = \frac{d\phi(z)}{dz} dz, \text{ or } -\mu R + \frac{dU}{dz} = \frac{d\phi(z)}{dz}.$$

To be able to determine $\phi(z)$, the left side of the last equation must reduce itself to a function of z by combining it, if necessary, with the equation $U = \phi(z)$. Therefore, if we suppose that we have taken the value of y or x in

the equation $U = \phi(z)$, and substituted it in the quantity $-\mu R + \frac{dU}{dz}$, the differential coefficient of that quantity with respect to x in the first supposition, or with respect to y in the second, must be equal to nothing.

Let us develop, for instance, $\frac{d\left(-\mu R + \frac{dU}{dz}\right)}{dy}$, we shall find, in considering x as a function of y ,

$$-\mu \left(\frac{dR}{dy} + \frac{dR}{dx} \cdot \frac{dx}{dy} \right) - R \left(\frac{d\mu}{dy} + \frac{d\mu}{dx} \cdot \frac{dx}{dy} \right) + \frac{d^2 U}{dy dz} + \frac{d^2 U}{dx dz} \cdot \frac{dx}{dy} = 0,$$

$$\text{but } \frac{d^2 U}{dy dz} = \frac{d}{dz} \cdot \frac{dU}{dy} = \frac{d\mu Q}{dz}, \quad \frac{d^2 U}{dx dz} = \frac{d}{dz} \cdot \frac{dU}{dx} = \frac{d\mu P}{dz}, \quad \frac{dx}{dy} = -\frac{Q}{P}.$$

We have also, according to the condition by which μ was determined,

$$\frac{d\mu P}{dy} = \frac{d\mu Q}{dx}, \text{ or } \frac{\mu dP}{dy} - \mu \frac{dQ}{dx} = \frac{Q d\mu}{dx} - \frac{P d\mu}{dy} = -P \left(\frac{d\mu}{dy} + \frac{d\mu}{dx} \cdot \frac{dx}{dy} \right);$$

and these values being substituted will give

$$R\left(\frac{dP}{dy} - \frac{dQ}{dx}\right) + Q\left(\frac{dR}{dx} - \frac{dP}{dz}\right) + P\left(\frac{dQ}{dz} - \frac{dR}{dy}\right) = 0,$$

which is precisely the same equation we have found (178.)

(180.) Hence results the means to integrate a total differential equation of three variables, in which the above condition is satisfied.

Let, for instance, the proposed equation be $dx (ay - bz) + dy (cz - ax) + dz (bx - cy) = 0$, in which the coefficients of dx, dy, dz render identical the above equation of condition. If we suppose z to be constant, the term multiplied by dz vanishes, and we have simply $dx (ay - bz) + dy (cz - ax) = 0$, or

$$\frac{dx}{cz - ax} + \frac{dy}{ay - bz} = 0.$$

Integrating, we find,

$$\frac{1}{a} \log \left(\frac{ay - bz}{cz - ax} \right) = c.$$

Let us assume now $c = \phi(z)$, we shall have to determine $\phi(z)$ the following equation, in observing that here

$$\mu = \frac{1}{(ay - bz)(cz - ax)}, \text{ and } R = bx - cy,$$

$$\frac{-(bx - cy)}{(ay - bz)(cz - ax)} + \frac{1}{a} \frac{d}{dz} \log \left(\frac{ay - bz}{cz - ax} \right) = \frac{d\phi(z)}{dz}.$$

Generally, it would be necessary to substitute in this equation for x or y their values derived from the equation

$\frac{1}{a} \log \left(\frac{ay - bz}{cz - ax} \right) = \phi(z)$, but in this case after having performed the differentiation which is indicated, it will be

found, that the left side is reduced to nothing. Hence it will follow,

$$\frac{d\phi(z)}{dz} = 0,$$

or $\phi(z)$ a constant quantity, consequently the integral of the proposed equation will be

$$\frac{1}{a} \log \left(\frac{ay - bz}{cz - ax} \right) = C,$$

or, by changing the arbitrary constant,

$$\frac{ay - bz}{cz - ax} = C.$$

It is easy to verify that result; for by differentiating the equation, and considering x, y , and z as variables, we find

$$\frac{a dx (ay - bz) + a dy (cz - ax) + a dz (bx - cy)}{(cz - ax)^2} = 0,$$

an equation which differs only from the proposed by the factor $\frac{a}{(cz - ax)^2}$.

We shall apply this method of integration to another example. The proposed equation is

$$(y^2 + yz + z^2) dx + (x^2 + xz + z^2) dy + (x^2 + xy + y^2) dz = 0.$$

If we consider z as a constant quantity, the last term disappears, and by dividing by the product of the coefficients of dx and dy , the variables are separated, and we have

$$\frac{dx}{x^2 + xz + z^2} + \frac{dy}{y^2 + yz + z^2} = 0.$$

Integrating, we find

$$\frac{2}{z\sqrt{3}} \left\{ \tan^{-1} \frac{z+2x}{z\sqrt{3}} + \tan^{-1} \frac{z+2y}{z\sqrt{3}} \right\} = C.$$

Considering, now C or its product by $\frac{2}{z\sqrt{3}}$, as a function of z , we shall have the tangent of the left side of the equation equal to the tangent of the right side, which will still be a function of z ; we shall represent by Z . Thus we find in including the factor $\frac{1}{z\sqrt{3}}$ in the function, Z ,

$$\frac{x + y + z}{z^2 - zx - zy - 2xy} = Z$$

z is to be determined by the condition that the last equation should satisfy the proposed differential equation. This last equation being differentiated gives

$$2(y^2 + yz + z^2) dx + 2(x^2 + xz + z^2) dy + (x^2 + y^2 - z^2 - 2xy - 2zy) dz = (z^2 - zx - zy - 2xy)^2 dZ,$$

which, being subtracted from the double of the proposed equation, becomes

$$(x^2 + y^2 + z^2 + 2xy + 2xz + 2yz) dz = (z^2 - zx - zy - 2xy)^2 dZ, \text{ or}$$

$$(x + y + z)^2 dz = - (z^2 - zx - zy - 2xy)^2 dZ$$

But we have found

$$(x + y + z) = Z(z^2 - zx - zy - 2xy);$$

by combining these two equations we shall have, therefore,

$$dz = \frac{-dz}{Z^2},$$

which being integrated gives

$$z + c = \frac{1}{Z}, \text{ or } Z = \frac{1}{z + c}.$$

Substituting this value of Z , we find for the integral of the proposed equation

$$\frac{x + y + z}{z^2 - zx - zy - 2xy} = \frac{1}{z + c}, \text{ or } c(x + y + z) + 2(xz + yz + xy) = 0,$$

or again, by putting zc instead of c ,

$$c(x + y + z) + xz + yz + xy = 0.$$

(181.) If the proposed differential equation contain the quantities dx, dy, dz in a degree higher than the first, it can only be integrated by the preceding method, when it can be decomposed into rational factors of the form $Pdx + Qdy + Rdz$; for it is obvious that whatever the integral may be, it is always possible to derive from it by differentiation an expression of the form $dz = pdx + qdy$, in which p and q designate any function whatever of x, y , and z .

If, for instance, the proposed equation be

$$P dx^2 + Q dy^2 + R dz^2 + 2S dx dy + 2T dx dz + 2V dy dz = 0,$$

we shall derive from it a value of dz containing a radical quantity, and unless the quantity under the radical be a perfect square, the decomposition into factors cannot take place. It is, therefore, necessary that this quantity, which in the present case is

$$(T^2 - PR) dx^2 + 2(TV - RS) dx dy + (V^2 - QR) dy^2,$$

should be a perfect square, which can only take place under the condition

$$(TV - RS)^2 - (T^2 - PR)(V^2 - QR) = 0.$$

(182.) It is easy to generalize these principles, and to obtain conditions of integrability for total differential equations of four or more variables. The number of equations of condition is, however, greater. If the number of variables be m , the number of equations of condition will be $(m-1)(m-2)$.

(183.) The number of equations of condition of integrability becomes also greater, when the proposed differential equations are of an order higher than the first. Let $V = 0$ be the differential equation, and let V be a function of $x, y, z, x_1, y_1, z_1, x_2, y_2, z_2$, the six last quantities being as in number (109.) respectively equal to $dx, d^2x, dy, d^2y, dz, d^2z$, &c. If, then, we designate by μ a function of x, y, z, x_1, y_1, z_1 , which will render μV an exact differential, we shall have, according to (109.), the following equations,

$$\frac{d \cdot \mu V}{dx} - d \frac{d \cdot \mu V}{dx_1} + d^2 \frac{d \cdot \mu V}{dx_2} = 0$$

$$\frac{d \cdot \mu V}{dy} - d \frac{d \cdot \mu V}{dy_1} + d^2 \frac{d \cdot \mu V}{dy_2} = 0.$$

$$\frac{d \cdot \mu V}{dz} - d \frac{d \cdot \mu V}{dz_1} + d^2 \frac{d \cdot \mu V}{dz_2} = 0.$$

Which being developed become

$$\mu \left(\frac{dV}{dx} - d \frac{dV}{dx_1} + d^2 \frac{dV}{dx_2} \right) - d\mu \left(\frac{dV}{dx_1} - 2d \frac{dV}{dx_2} \right) + d^2 \mu \frac{dV}{dx_2} = 0.$$

$$\mu \left(\frac{dV}{dy} - d \frac{dV}{dy_1} + d^2 \frac{dV}{dy_2} \right) - d\mu \left(\frac{dV}{dy_1} - 2d \frac{dV}{dy_2} \right) + d^2 \mu \frac{dV}{dy_2} = 0.$$

$$\mu \left(\frac{dV}{dz} - d \frac{dV}{dz_1} + d^2 \frac{dV}{dz_2} \right) - d\mu \left(\frac{dV}{dz_1} - 2d \frac{dV}{dz_2} \right) + d^2 \mu \frac{dV}{dz_2} = 0$$

Since μ does not contain x_2, y_2, z_2 , and that the terms multiplied by V and dV are reduced to nothing since $V = 0$. If we now eliminate μ and its differentials, between these equations we shall obtain two equations of condition, in which z_2 and z_3 may be replaced by their values derived from $V = 0$ and $dV = 0$.

Let the equation be

$$(x dx + z dz) d^2y - z dy d^2z - dy (dx^2 + dy^2 + dz^2) = 0.$$

We have

$$V = (xx_1 + zz_1)y_2 - zz_2y_1 - y_1(x^2 + y^2 + z^2).$$

The first of the above equations becomes useless, because dx is considered as a constant quantity, and we have simply

$$\frac{dV}{dy} = 0, \quad \frac{dV}{dy_1} = -zz_2 - x_1^2 - y_1^2 - z_1^2, \quad \frac{dV}{dy_2} = xx_1 + zz_1, \quad \frac{dV}{dz} = z_1y_2 - z_2y_1,$$

$$\frac{dV}{dz_1} = zy_2 - 2y_1z_1, \quad \frac{dV}{dz_2} = -zy_1.$$

These values substituted in the second and third of the above equations, give

$$(6z_1z_2 + 6y_1y_2 + 2zz_2)\mu + (3x_1^2 + 3y_1^2 + 3z_1^2 + 3zz_2)d\mu + (xx_1 + zz_1)d^2\mu = 0.$$

$$2y_2\mu + 3y_2d\mu + y_1d^2\mu = 0.$$

If first we eliminate $d^2\mu$, we shall find

$$(6y_1z_1z_2 + 6y_1^2y_2 + 2zz_2y_1 - 2xx_1y_2 - 2zz_1y_2)\mu + (3x_1^2y_1 + 3y_1^2 + 3y_1z_1^2 + 3y_1zz_2 - 3xx_1y_2 - 3zz_1y_2)d\mu = 0.$$

We need not eliminate μ and $d\mu$, for if we substitute in this last equation for z_2 and z_3 their values derived from $V = 0$ and $dV = 0$, the left side is reduced to nothing.

(184.) Let us determine, now, the conditions which ought to be satisfied in order that a differential equation containing three or a greater number of variables, and of an order superior to the first, should have a second, or third integral.

Let $V_2 = 0$ be a differential equation, and μ_2 the factor which renders $\mu_2 V_2$ an exact differential. According to what precedes, the following equations, the number of which is the same as that of the variables, will be satisfied.

Integral
Calculus.

Part III.

$$\left(\frac{dV_2}{dx} - d\frac{dV_2}{dx_1} + d^2\frac{dV_2}{dx_2} - \&c.\right)\mu_2 - \left(\frac{dV_2}{dx_1} - 2d\frac{dV_2}{dx_2} + \&c.\right)d\mu_2 + \left(\frac{dV_2}{dx_2} - \&c.\right)d^2\mu_2 - \&c.\dots = 0.$$

Secondly, V_1 being the integral of $\mu_2 V_2$, it will be necessary that there exist a factor μ_1 which can render $\mu_1 V_1$ an exact differential, in order that the proposed differential equation should have a second integral, and this cannot take place unless the following equations are satisfied,

$$\left(\frac{dV_1}{dx} - d\frac{dV_1}{dx_1} + d^2\frac{dV_1}{dx_2} - \&c.\right)\mu_1 - \left(\frac{dV_1}{dx_1} - 2d\frac{dV_1}{dx_2} + \&c.\right)d\mu_1 + \left(\frac{dV_1}{dx_2} - \&c.\right)d^2\mu_1 - \&c.\dots = 0$$

But since V_1 is the integral of $\mu_2 V_2$, we have

$$\frac{dV_1}{dx} = \frac{d \cdot \mu_2 V_2}{dx_1} - d\frac{d \cdot \mu_2 V_2}{dx_2} + d^2\frac{d \cdot \mu_2 V_2}{dx_3} - \&c. \quad \frac{dV_1}{dx_1} = \frac{d \cdot \mu_2 V_2}{dx_2} - d\frac{d \cdot \mu_2 V_2}{dx_3} + \&c. \\ \frac{dV_1}{dx_2} = \frac{d \cdot \mu_2 V_2}{dx_3} - \&c., \&c.$$

These values being substituted in the above equations will give

$$\left(\frac{d \cdot \mu_2 V_2}{dx_1} - 2d\frac{d \cdot \mu_2 V_2}{dx_2} + 3d^2\frac{d \cdot \mu_2 V_2}{dx_3} - \&c.\right)\mu - \left(\frac{d \cdot \mu_2 V_2}{dx_2} - 3d\frac{d \cdot \mu_2 V_2}{dx_3} + \&c.\right) \\ d\mu + \left(\frac{d \cdot \mu_2 V_2}{dx_3} - \&c.\right)d^2\mu - \&c.\dots = 0.$$

Developing these last equations, and observing that the differentials of the same order as V_2 do not enter in V_1 , and that all the terms which will be multiplied by V_2 , dV_2 , d^2V_2 , after the differentiations, will disappear, since we have $V_2 = 0$, $dV_2 = 0$, $d^2V_2 = 0$, &c., we shall find

$$\left(\mu_2 \frac{dV_2}{dx_1} - 2d\mu_2 \frac{dV_2}{dx_2} + 3d^2\mu_2 \frac{dV_2}{dx_3} - \&c.\right)\mu_1 - \left(\mu_2 \frac{dV_2}{dx_2} - 3d\mu_2 \frac{dV_2}{dx_3} + \&c.\right) \\ d\mu_1 + \left(\mu_2 \frac{dV_2}{dx_3} - \&c.\right)d^2\mu - \&c.\dots = 0.$$

Each variable will give a similar equation, which, with those relative to the first integral, will be all the equations of condition. In an analogous manner, the conditions relative to the existence of a third integral might be found.

(185.) When the proposed total differential equation is not an exact differential, nor can become so by the multiplication of a factor properly chosen, no primitive equation between the variables can satisfy it. In that case, it is always possible, however, to find a system of equations between the variables which, conjointly, satisfy the proposed equation.

In the equation $dz - ay dx - b dy = 0$, for instance, the left side is not an exact differential, and the equation of condition found (178.) not being satisfied, it is impossible to discover a factor which would make it so; but if

we assume $y = \frac{dX}{dx} = X'$, where X is an arbitrary function of x , the equation will become $dz = aX'dx + b dX'$,

and consequently $z = aX + bX'$, including the constant in the arbitrary function. Hence the system of equations $y = X'$ and $z = aX + bX'$, constitute the integral of the proposed equation.

(186.) Generally, let $Pdx + Qdy + Rdz = 0$ be the proposed equation, and integrate it, in supposing first z to be constant, in which case the equation is reduced to $Pdx + Qdy = 0$. Let the factor by which the left side of this equation ought to be multiplied to become an immediate differential, be represented by μ , and the integral by $U = C$. If we differentiate this last equation with respect to x , y , z and C , and if we subtract from

it the proposed equation multiplied by μ , we shall find $\frac{dC}{dz} = \frac{dU}{dz} - \mu R$. The right side of this equation is no

longer a function of z only, since the equation of condition found (178.) is not satisfied; but it is obvious that by supposing $C = \phi z$, an arbitrary function of z , the proposed differential equation will be satisfied by

$U = \phi(z)$, provided we have at the same time $\frac{d\phi(z)}{dz} = \frac{dU}{dz} - \mu R$. In other words, the system of the two

equations

$$U = \phi(z), \quad \frac{dU}{dz} - \mu R = \frac{d\phi(z)}{dz},$$

will constitute the integral of $P dx + Q dy + R dz = 0$.

This process being applied to the equation

$$\frac{dz}{z-c} = \frac{z dx + y dy}{x(x-a) + y(y-b)},$$

will give for the integral the two equations

$$x^2 + y^2 = \phi(z), \quad 2 \frac{x(x-a) + y(y-b)}{z-c} = \frac{d\phi(z)}{dz}.$$

(187.) It is easy to extend these considerations to equations containing more than three variables when the differentials are not in a degree higher than the first. If, for instance, we had an equation between four variables,

$$N du + P dx + Q dy + R dz = 0,$$

satisfying none of the conditions of integrability, we would first integrate it in considering two of the variables, u and x , as constants. The equation, in that supposition, becomes $Q dy + R dz = 0$; let μ be the factor which renders it an immediate differential, and let $\int \mu (Q dy + R dz) = U$, then $U = c$ would be the integral of the equation. If we differentiate it, in considering u, x, y, z and C as variables, and subtract it from the proposed equation multiplied by μ , we shall get

$$\frac{dU}{du} du + \frac{dU}{dx} dx - dC = \mu N du + \mu P dx.$$

To satisfy this equation, it is necessary to assume $C = \phi(u, x)$, ϕ designating an arbitrary function; and if we suppose

$$d\phi(u, x) = \phi_1(u, x) du + \phi_2(u, x) dx,$$

we shall have, in equalizing the coefficients of du , in both sides of the equation, as well as those of dx ,

$$\frac{dU}{du} - \phi_1(u, x) = \mu N, \quad \frac{dU}{dx} - \phi_2(u, x) = \mu P;$$

and, thus, the proposed equation will be satisfied by the system of the three equations

$$U = \phi(u, x), \quad \frac{dU}{du} - \mu N = \phi_1(u, x), \quad \frac{dU}{dx} - \mu P = \phi_2(u, x),$$

which contain an arbitrary function of two quantities.

There is a simpler means of satisfying the proposed equation; for if we eliminate the variables z and y between the three equations above, the resulting equation will contain only $x, u, \phi(x, u), \phi_1(x, u), \phi_2(x, u)$, that is will be an equation between x, u , the function ϕ , and its partial differential coefficients ϕ_1 and ϕ_2 . If by means of this equation the function ϕ can be determined, its value will contain, as will soon be shown, an arbitrary function of u and x ; and this value being substituted in the three equations, one of them may be suppressed, and the two remaining will satisfy conjointly the proposed differential equation.

Let us take as an example the differential equation

$$x du + y dx + u dy + z dz = 0,$$

which satisfies none of the conditions of integrability. We shall have

$$\mu = 2U = \int 2(u dy + z dz) = 2uy + z^2,$$

and consequently the integral may be represented by the system of the three equations

$$2uy + z^2 = \phi(u, x), \quad 2y - 2x = \phi_1(u, x), \quad -2y = \phi_2(u, x).$$

If we eliminate y between the two last of these equations, we get

$$\phi_1(u, x) + \phi_2(u, x) = -2x,$$

a partial differential equation, the integral of which, according to the method hereafter to be explained, is

$$\phi(u, x) + x^2 = \psi(u, x),$$

ψ being an arbitrary function. The value of $\phi(u, x)$ being substituted in the two first equations will give

$$x^2 + z^2 + 2uy = \psi(u - x), \quad 2y - 2x = \psi'(u - x).$$

ψ' representing the differential coefficient of ψ , which conjointly will satisfy the proposed differential equation.

(188.) The differential equations in which the differentials are in a degree higher than the first may be integrated in a similar manner, when the conditions of integrability are not satisfied. Let the equation be $dz^2 = a^2(dx^2 + dy^2)$. If we suppose y constant, it becomes $dz = m dy$, and gives consequently $z = my + C$. Let $C = \phi(x)$ and $dC = \phi'(x) dx$, and differentiate the equation $z = my + C$, in considering x, y , and z as variables, we shall find $dz = m dy + \phi'(x) dx$; and since this value ought to satisfy the proposed equation, we shall have

$$2dy = \frac{m dx}{\phi'(x)} - \frac{\phi'(x) \cdot dx}{m},$$

Part III.
Integral
Calculus.

and hence, by integration,

$$2y = m \int \frac{dx}{\phi'(x)} - \frac{1}{m} \phi(x).$$

The proposed equation, therefore, is satisfied by the system of the two equations

$$z = my + \phi(x), \quad 2y = m \int \frac{dx}{\phi'(x)} - \frac{1}{m} \phi(x) + A,$$

 A, being an arbitrary constant, and ϕ an arbitrary function of x .

Another system of two equations may be found by the following process. Let $\frac{dx}{dz} = a$, and $\frac{dy}{dz} = a$, a and a being constants, the proposed equation will be satisfied provided the constants a and a satisfy the equation $1 = m^2(a^2 + a^2)$. This gives $a = \frac{\sqrt{1 - m^2 a^2}}{m}$; substituting this value and integrating the two equations

$$\frac{dx}{dz} = a, \text{ and } \frac{dy}{dz} = \frac{\sqrt{1 - m^2 a^2}}{m},$$

we shall have

$$x = az + b, \quad y = \frac{z \sqrt{1 - m^2 a^2}}{m} + c,$$

 which contain three arbitrary constants, a, b, c , and satisfy the proposed equation. This is easy to verify, for if we differentiate each of these equations, the two constants b and c will disappear, and we shall get

$$dx = a dz, \quad dy = \frac{dz \sqrt{1 - m^2 a^2}}{m};$$

 and eliminating a between these two we shall find the proposed equation.

 It is also obvious that if a, b, c , instead of being constant, are variable quantities, the two equations written above will still satisfy the proposed equation, provided that equation may be obtained by the elimination of a, b, c . But if we differentiate the two equations, in the supposition of a, b, c , variables, we find

$$dx = a dz + z da + db, \quad dy = \frac{dz \sqrt{1 - m^2 a^2}}{m} - \frac{m z a da}{\sqrt{1 - m^2 a^2}} + dc.$$

 These values of dx and dy will be reduced to those we have found in the supposition of a, b , and c , constant, if we suppose

$$z da + db = 0, \quad - \frac{m z a da}{\sqrt{1 - m^2 a^2}} + dc = 0;$$

 and if we can find the variable values of a, b, c , which satisfy these equations, we shall obtain a new system of two equations satisfying the proposed equation. Let $a = \phi(b)$, and $c = \psi(b)$, then the two last equations and the two equations

$$x = az + b, \quad y = \frac{z \sqrt{1 - m^2 a^2}}{m} + c,$$

become

$$x = z \phi(b) + b, \quad 0 = z \phi'(b) + 1, \quad y = \frac{z \sqrt{1 - m^2 \phi(b)^2}}{m} + \psi(b), \quad 0 = \frac{-m z \phi(b) \phi'(b)}{\sqrt{1 - m^2 \phi(b)^2}} + \psi'(b),$$

which may be put under the following form,

$$\begin{aligned} \frac{x-b}{z} - \phi(b) = 0, \quad -\frac{1}{z} - \phi'(b) = 0, \quad \frac{y - \psi(b)}{z} - \frac{\sqrt{1 - m^2 \left(\frac{x-b}{z}\right)^2}}{m} = 0, \\ -\psi'(b) - \frac{m \left(\frac{x-b}{z}\right)}{\sqrt{1 - m^2 \left(\frac{x-b}{z}\right)^2}} = 0. \end{aligned}$$

The last of these equations may be identified with the fourth by taking a proper value for the arbitrary function ϕ , since they both express a rotation between the quantities $\frac{x-b}{z}$ and b ; we may, therefore, instead of the second equation, which is the differential of the first in considering b only as variable, by the differential of the fourth in the same supposition, or which is still the same thing, by the second differential of the third.

 If, therefore, we represent this third equation by $U = 0$, we shall have, instead of the four equations above,

$$U = 0, \quad \frac{dU}{db} = 0, \quad \frac{d^2 U}{db^2} = 0,$$

Integral
Calculus.

which contain only one arbitrary function, and if a particular value be assigned to this function, and then the quantity b eliminated between the three equations, we shall obtain two primitive equations satisfying the proposed. Part III.

This may be generalized, and the same process applied to any equation

$$F\left(\frac{dx}{dz}, \frac{dy}{dz}\right) = 0.$$

From this equation we may derive the value of $\frac{dy}{dz}$. Let $\frac{dy}{dz} = f\left(\frac{dx}{dz}\right)$, and assume $\frac{dx}{dz} = a$, we shall have

$\frac{dy}{dz} = f(a)$, which being integrated give

$$x = az + b, \quad y = z f(a) + c, \quad \text{or} \quad \frac{x-b}{z} = a = \frac{y-c}{z} = f\left(\frac{x-b}{z}\right).$$

If we assume then $a = \phi(b)$, $c = \psi(b)$, and if we differentiate with respect to b , we shall have

$$\frac{x-b}{z} - \phi(b) = 0, \quad -\frac{1}{z} - \phi'(b) = 0, \quad \frac{y-\psi(b)}{z} - f\left(\frac{x-b}{z}\right) = 0, \quad -\psi'(b) + f\left(\frac{x-b}{z}\right) = 0,$$

the first and last of which may be identified, and consequently the second replaced by the differential of the last, considering b only as variable. Let

$$\frac{y-\psi(b)}{z} - f\left(\frac{x-b}{z}\right) = U.$$

It is obvious that the above four equations will be reduced to the three following,

$$U = 0, \quad \frac{dU}{db} = 0, \quad \frac{d^2U}{db^2} = 0,$$

and it is moreover obvious that instead of U , we may write

$$F\left(\frac{x-b}{z}, \frac{y-\psi(b)}{z}\right)$$

In the example treated above, this last proposition is easily verified, in making the radical quantities disappear in the equation corresponding to $U = 0$, for then it becomes

$$1 = m \left\{ \left(\frac{x-b}{z} \right)^2 + \left(\frac{y-\psi(b)}{z} \right)^2 \right\},$$

which is precisely the proposed equation in which $\frac{x-b}{z}$, and $\frac{y-\psi(b)}{z}$ have been substituted respectively for

$$\frac{dx}{dz}, \quad \frac{dy}{dz}$$

(199.) Total differential equations of an order higher than the first, which do not satisfy the conditions of integrability, are treated like those of the first order.

We shall only consider here the equation $M d^2x + N d^2y + P dx^2 = Q dz^2$, in which dz is supposed to be constant, and M, N, P, Q to represent functions of x, y, z, dx, dy, dz , such as when the left side of the equation is multiplied by μ , it becomes an exact differential with respect to the factors x and y . If U' represent the first integral of that differential, and if it be of the n^{th} degree with respect to dx, dy, dz , we shall assume it equal to a function of z , multiplied by dz^n , and we shall have the equation $U' = \phi'(z) dz^n$. The differential being then taken in considering x, y, dx, dy , and z as variables, and compared with the proposed equation, will give

$$\phi''(z) dz^n - \frac{dU'}{dz} = \mu Q dz,$$

since by the supposition we have made

$$\frac{dU'}{dz} dz^2 x + \frac{dU'}{dz^2 y} dz^2 y + \frac{dU'}{dz} dx + \frac{dU'}{dz} dy = \mu M d^2x + \mu N d^2y + \mu P dx^2.$$

The proposed equation will, therefore, be satisfied by the equations

$$U' = \phi'(z) dz^n, \quad \frac{dU'}{dz} = \phi''(z) dz^n - \mu Q dz,$$

taken conjointly. To obtain the second integral of the proposed equation, without assuming any particular value for $\phi(z)$, it will be necessary to derive from the two last equations two equations which can be integrated in considering x, y, z , and $\phi(z)$ as distinct variables. Let us take for an example the equation

$$z dz d^2x - 2 dy d^2y = z dz^2$$

Integral
Calculus.

By the above process we shall find that it is satisfied by the equations

$$z dz dx - dy^2 = \phi'(z) dz^2, \quad dx = \phi''(z) dz - z dz;$$

the last of these being integrated, gives $2x = 2\phi'(z) - z^2$, and substituting in the first the value of dx derived from this integral, we shall find

$$dy = dz \sqrt{z\phi''(z) - \phi'(z) - z^2},$$

from which we shall conclude that the second integral of the proposed equation is represented by the two following equations,

$$2x = 2\phi'(z) - z^2, \quad y = \int dz \sqrt{z\phi''(z) - \phi'(z) - z^2}.$$

Integration of Partial Differential Equations.

(190.) The determination of functions of several variables by means of given relations or equations between the functions, the variables, and some of, or all, the partial differential coefficients of the functions with respect to the variables, is one of the most important subjects of the Integral Calculus. Hitherto very few of the numerous cases which this determination presents have been successfully treated, and what has been done is the result of the labours of the most celebrated Mathematicians.

We cannot enter here into all the details of this extensive branch of analysis; and we shall only be able, not to exceed our limits, to mention some of the simplest, most remarkable, and useful cases. For more information on the subject, we must refer the reader to the II^d and III^d volumes of Lacroix's complete treatise on the Differential and Integral Calculus, to the transactions of learned societies, the *Journal de l'Ecole Polytechnique*, *Les Annales de Mathématiques de Gergonne*, *Le Journal de Crelles*, and *Les Exercices Mathématiques de Cauchy*.

(191.) Before entering into the subject of partial differential equations, we shall first consider the following question.

Let $x, x_1, x_2, x_3, \dots, x_n$ be $(n+1)$ variables, and let it be required to determine the values of n of these variables, of $x_1, x_2, \dots, x_n$, for instance, in function of x , by means of n given differential equations between these variables, containing only the first differential coefficients of $x_1, x_2, \&c.$ with respect to x . In this supposition, the n given equations may always be reduced to the following form,

$$\frac{dx_1}{dx} = \frac{X_1}{X}, \quad \frac{dx_2}{dx} = \frac{X_2}{X}, \quad \dots \quad \frac{dx_n}{dx} = \frac{X_n}{X},$$

or written in the form of propositions, $dx : dx_1 : dx_2 : \dots : dx_n :: X : X_1 : X_2 : \dots : X_n$, where any one of the variables may be considered as the independent variable, and where $X, X_1, X_2, \dots, X_n$ are functions of $x, x_1, x_2, \dots, x_n$.

It is easy to eliminate between these n equations $n-1$ variables, for instance $x_2, x_3, \dots, x_n$. It is sufficient for that, to differentiate $n-1$ consecutive times the first equation $\frac{dx_1}{dx} = \frac{X_1}{X}$, and to substitute each time for $\frac{dx_2}{dx}, \frac{dx_3}{dx}, \&c.$ their values derived from the $n-1$ last equations. We shall thus obtain the values of

$$\frac{dx_1}{dx}, \quad \frac{d^2 x_1}{dx^2}, \quad \frac{d^3 x_1}{dx^3}, \quad \dots \quad \frac{d^n x_1}{dx^n},$$

in functions of $x, x_1, x_2, \dots, x_n$. Eliminating then between these n equations the $n-1$ variables $x_2, x_3, \dots, x_n$, we shall find a final equation of the form

$$\phi\left(x, x_1, \frac{dx_1}{dx}, \frac{d^2 x_1}{dx^2}, \dots, \frac{d^n x_1}{dx^n}\right) = 0.$$

This equation being of the n^{th} order has n first integrals of the $(n-1)^{\text{th}}$ order, containing each an arbitrary constant. Let these equations be

$$F_1\left(x, x_1, \frac{dx_1}{dx}, \frac{d^2 x_1}{dx^2}, \dots, \frac{d^{n-1} x_1}{dx^{n-1}}\right) = c_1,$$

$$F_2\left(x, x_1, \frac{dx_1}{dx}, \frac{d^2 x_1}{dx^2}, \dots, \frac{d^{n-1} x_1}{dx^{n-1}}\right) = c_2,$$

$$\dots \dots \dots$$

$$F_n\left(x, x_1, \frac{dx_1}{dx}, \frac{d^2 x_1}{dx^2}, \dots, \frac{d^{n-1} x_1}{dx^{n-1}}\right) = c_n,$$

where $c_1, c_2, \dots, c_n$ designate the arbitrary constants. If we substitute now in these equations for $\frac{dx_1}{dx}$,

$\frac{d^2 x_1}{dx^2}, \dots, \frac{d^{n-1} x_1}{dx^{n-1}}$, their values derived from the first equation $\frac{dx_1}{dx} = \frac{X_1}{X}$, we shall have the n required equa-

Part III.

Integral
Calculus.

tions between the n variables $x, x_1, \dots, x_n$, they will contain n arbitrary constants. They are the integrals of the n proposed differential equations. Part III.

(192.) The n equations last mentioned containing n arbitrary constants, may always be supposed to have been resolved with respect to the constants, and put under the following form,

$$\phi_1 = c_1, \quad \phi_2 = c_2, \dots, \phi_n = c_n.$$

If these are differentiated, the arbitrary constants disappear, and we get

$$\frac{d\phi_1}{dx} \cdot dx + \frac{d\phi_1}{dx_1} dx_1 + \dots + \frac{d\phi_1}{dx_n} dx_n = 0.$$

$$\frac{d\phi_2}{dx} \cdot dx + \frac{d\phi_2}{dx_1} dx_1 + \dots + \frac{d\phi_2}{dx_n} dx_n = 0.$$

$$\dots \dots \dots$$

$$\frac{d\phi_n}{dx} \cdot dx + \frac{d\phi_n}{dx_1} dx_1 + \dots + \frac{d\phi_n}{dx_n} dx_n = 0$$

These differential equations are satisfied by the equations

$$\phi_1 = c_1, \quad \phi_2 = c_2, \dots, \phi_n = c_n,$$

therefore they must agree with the proposed differential equations

$$\frac{dx_1}{dx} = \frac{X_1}{X}, \quad \frac{dx_2}{dx} = \frac{X_2}{X}, \dots, \frac{dx_n}{dx} = \frac{X_n}{X}, \text{ or } dx : dx_1 : dx_2 : \dots : dx_n :: X : X_1 : X_2 : \dots : X_n.$$

Consequently, if the values of $dx_1, dx_2, \dots, dx_n$ are taken in these last equations, and substituted in those with which they agree, we shall obtain the n following identical equations :

$$\left. \begin{aligned} \frac{d\phi_1}{dx} X + \frac{d\phi_1}{dx_1} X_1 + \frac{d\phi_1}{dx_2} X_2 + \dots + \frac{d\phi_1}{dx_n} X_n &= 0. \\ \frac{d\phi_2}{dx} X + \frac{d\phi_2}{dx_1} X_1 + \frac{d\phi_2}{dx_2} X_2 + \dots + \frac{d\phi_2}{dx_n} X_n &= 0. \\ \dots \dots \dots \\ \frac{d\phi_n}{dx} X + \frac{d\phi_n}{dx_1} X_1 + \frac{d\phi_n}{dx_2} X_2 + \dots + \frac{d\phi_n}{dx_n} X_n &= 0. \end{aligned} \right\} \quad (A)$$

The solution of the proposed question (191.), that is the integration of the n proposed differential equations, may therefore be considered as satisfying this other question : to find n different functions, each of which being substituted for ϕ , shall make the equation identical,

$$\frac{d\phi}{dx} \cdot X + \frac{d\phi}{dx_1} X_1 + \frac{d\phi}{dx_2} X_2 + \dots + \frac{d\phi}{dx_n} X_n = 0.$$

It is moreover easy to see that if the functions $\phi_1, \phi_2, \dots, \phi_n$ satisfy this condition, it will still be the same with respect to any compound function of these. For let $\pi(\phi_1, \phi_2, \dots, \phi_n)$ be such a function, if we multiply the equations (A) respectively by $\frac{d\pi}{d\phi_1}, \frac{d\pi}{d\phi_2}, \frac{d\pi}{d\phi_3}, \dots$, &c., and if we add them, we shall find

$$\frac{d\pi}{dx} X + \frac{d\pi}{dx_1} X_1 + \frac{d\pi}{dx_2} X_2 + \dots + \frac{d\pi}{dx_n} X_n = 0,$$

so that π satisfies also the condition.

(193.) The integration of partial differential equations of the first order, and of the first degree, results immediately from what precedes.

Let the proposed equation be

$$X = X_1 \frac{dx}{dx_1} + X_2 \frac{dx}{dx_2} + \dots + X_n \frac{dx}{dx_n},$$

where $\frac{dx}{dx_1}, \frac{dx}{dx_2}, \dots, \frac{dx}{dx_n}$, are the partial differential coefficients of x with respect to $x_1, x_2, \dots, x_n$,

$X, X_1, X_2, \dots, X_n$ functions of these same variables.

Let $\pi = 0$ be the required relation between x and the variables $x_1, x_2, \dots, x_n$, or the integral of the proposed equation. We shall have, in differentiating successively with respect to $x_1, x_2, \dots, x_n$,

$$\frac{d\pi}{dx} \cdot \frac{dx}{dx} + \frac{d\pi}{dx_1} = 0.$$

$$\frac{d\pi}{dx} \cdot \frac{dx}{dx_1} + \frac{d\pi}{dx_1} = 0.$$

.....

$$\frac{d\pi}{dx} \cdot \frac{dx}{dx_n} + \frac{d\pi}{dx_n} = 0.$$

And if we substitute the values derived from these in the proposed equation, it becomes

$$\frac{d\pi}{dx} X + \frac{d\pi}{dx_1} X_1 + \frac{d\pi}{dx_2} X_2 + \dots + \frac{d\pi}{dx_n} X_n = 0.$$

We have just proved (192.) that such an equation is satisfied in taking for π any function whatever of $\phi_1, \phi_2, \phi_3, \dots, \phi_n$.

Hence to integrate a partial differential equation of the first order, and of the first degree, such as

$$X = \frac{dx}{dx_1} X_1 + \frac{dx}{dx_2} X_2 + \dots + \frac{dx}{dx_n} X_n,$$

it will be sufficient to integrate the system of the following equations,

$$\frac{dx_1}{dx} = \frac{X_1}{X}, \quad \frac{dx_2}{dx} = \frac{X_2}{X} \dots \dots \frac{dx_n}{dx} = \frac{X_n}{X},$$

or a system of n equations furnished by the proportions $dx : dx_1 : dx_2 : \dots : dx_n :: X : X_1 : X_2 : \dots : X_n$; and then, if $\phi_1 = c_1, \phi_2 = c_2, \dots, \phi_n = c_n$ represent their integrals, $c_1, c_2, \dots, c_n$, being the arbitrary constants, and if we designate by π any function whatever of $\phi_1, \phi_2, \dots, \phi_n$, $\pi = 0$ will be the required integral.

(194.) These considerations may still be generalized, and it may be demonstrated that if, as above,

$$\phi_1 = c_1, \phi_2 = c_2, \phi_3 = c_3, \dots, \phi_n = c_n$$

are the integrals of

$$\frac{dx_1}{dx} = \frac{X_1}{X}, \quad \frac{dx_2}{dx} = \frac{X_2}{X} \dots \dots \frac{dx_n}{dx} = \frac{X_n}{X},$$

or of a system of n equations furnished by the proportions $dx : dx_1 : dx_2 : \dots : dx_n :: X : X_1 : X_2 : \dots : X_n$, a system of m equations such as

$$\left. \begin{aligned} X &= X_m \frac{dx}{dx_m} + X_{m+1} \frac{dx}{dx_{m+1}} + \dots + X_n \frac{dx}{dx_n}, \\ X_1 &= X_m \frac{dx_1}{dx_m} + X_{m+1} \frac{dx_1}{dx_{m+1}} + \dots + X_n \frac{dx_1}{dx_n}, \\ &\dots \dots \dots \\ X_{m-1} &= X_m \frac{dx_{m-1}}{dx_m} + X_{m+1} \frac{dx_{m-1}}{dx_{m+1}} + \dots + X_n \frac{dx_{m-1}}{dx_n}, \end{aligned} \right\} \text{(B)}$$

in which $x, x_1, x_2, \dots, x_{m-1}$ are considered as functions of $x_m, x_{m+1}, \dots, x_n$, will be satisfied by the equations

$$\pi_1 = 0, \quad \pi_2 = 0 \dots \dots \pi_m = 0,$$

$\pi_1, \pi_2, \dots, \pi_m$ being arbitrary functions of $\phi_1, \phi_2, \dots, \phi_n$.

Before demonstrating this proposition, it must be remarked that the characteristic property of the partial differential equations (B) is, that each equation contains only the partial differential coefficients of the same variable, and that in all the equations the partial differential coefficients taken with respect to the same variable are identical.

Now let $A, B, C, \dots, M$, be m quantities so determined as to satisfy the $m - 1$ following equations,

$$\begin{aligned} A \frac{d\pi_1}{dx_1} + B \frac{d\pi_2}{dx_1} + C \frac{d\pi_3}{dx_1} + \dots + M \frac{d\pi_m}{dx_1} &= 0. \\ A \frac{d\pi_1}{dx_2} + B \frac{d\pi_2}{dx_2} + C \frac{d\pi_3}{dx_2} + \dots + M \frac{d\pi_m}{dx_2} &= 0. \\ &\dots \dots \dots \\ A \frac{d\pi_1}{dx_{m-1}} + B \frac{d\pi_2}{dx_{m-1}} + C \frac{d\pi_3}{dx_{m-1}} + \dots + M \frac{d\pi_m}{dx_{m-1}} &= 0 \end{aligned}$$

Let us also assume, for the sake of brevity,

$$A \frac{d\pi_1}{dx} + B \frac{d\pi_2}{dx} + C \frac{d\pi_3}{dx} + \dots + M \frac{d\pi_m}{dx} = N.$$

It is easy to derive from the preceding equations, the following:

$$\begin{aligned} N \frac{dx}{dx_m} &= - \left\{ A \frac{d\pi_1}{dx_m} + B \frac{d\pi_2}{dx_m} + \dots + M \frac{d\pi_m}{dx_m} \right\}. \\ N \frac{dx}{dx_{m+1}} &= - \left\{ A \frac{d\pi_1}{dx_{m+1}} + B \frac{d\pi_2}{dx_{m+1}} + \dots + M \frac{d\pi_m}{dx_{m+1}} \right\}. \\ &\dots\dots\dots \\ N \frac{dx}{dx_n} &= - \left\{ A \frac{d\pi_1}{dx_n} + B \frac{d\pi_2}{dx_n} + \dots + M \frac{d\pi_m}{dx_n} \right\}. \end{aligned}$$

And we shall be able to form in a similar manner, the values of the partial differential coefficients of $x_1, x_2, \dots, x_n$. But since $\pi_1, \pi_2, \dots, \pi_m$, are arbitrary functions of $\phi_1, \phi_2, \dots, \phi_n$, we have, according to (192.), the identical equations

$$\begin{aligned} \frac{d\pi_1}{dx} X + \frac{d\pi_1}{dx_1} X_1 + \frac{d\pi_1}{dx_2} X_2 + \dots + \frac{d\pi_1}{dx_n} X_n &= 0. \\ \frac{d\pi_2}{dx} X + \frac{d\pi_2}{dx_1} X_1 + \frac{d\pi_2}{dx_2} X_2 + \dots + \frac{d\pi_2}{dx_n} X_n &= 0. \\ &\dots\dots\dots \\ \frac{d\pi_m}{dx} X + \frac{d\pi_m}{dx_1} X_1 + \frac{d\pi_m}{dx_2} X_2 + \dots + \frac{d\pi_m}{dx_n} X_n &= 0. \end{aligned}$$

If we multiply now these equations respectively by $A, B, C, \dots, M$, and if we add them, we shall obtain, after the reductions which will take place in consequence of the preceding equations,

$$X = X_m \frac{dx}{dx_m} + X_{m+1} \frac{dx}{dx_{m+1}} + \dots + X_n \frac{dx}{dx_n},$$

which is the first of the equations A. By a similar process the others will be obtained.

(195.) The application of these general principles to particular cases presents no difficulty. We shall enumerate some of the most useful, and give a few examples in which the calculation can be completed.

When the proposed differential equation contains only one of the partial differential coefficients of $x, \frac{dx}{dx_1}$ for

instance, its most general form is $X = \frac{dx}{dx_1} X_1$, or $X dx_1 - X_1 dx = 0$; and since the quantities we have, in

the general case, represented by $X_2, X_3, \dots, X_n$, are all equal to nothing, the other differential equations, besides $X dx_1 - X_1 dx = 0$, are simply $dx_2 = 0, dx_3 = 0, \dots, dx_n = 0$. Consequently they may be integrated separately, and give $x_2 = c_2, x_3 = c_3, \dots, x_n = c_n$. Hence in the equation $X dx_1 - X_1 dx = 0$, all the variables but x and x_1 may be considered as constant quantities, and, therefore, it may be integrated as a differential equation between two variables. Let that integral be resolved with respect to the arbitrary constant, and be represented by $\phi_1 = c_1$, then, according to the general rule, (193.) the integral of the proposed differential equation will be $\pi(\phi_1, x_2, x_3, \dots, x_n) = 0$, or $\phi_1 = \psi(x_2, x_3, \dots, x_n)$, the right side of the equation being an arbitrary function of all the variables it contains.

Example 1. Let $\sqrt{y^2 - z^2} = z \frac{dz}{dx}$ be the proposed equation. Integrating, in considering y as a constant quantity, we find $x + \sqrt{y^2 - z^2} = c$, and, consequently, $x + \sqrt{y^2 - z^2} = \psi(y)$, where $\psi(y)$ is an arbitrary function of y , is the integral required.

Example 2. The equation $\frac{dz}{dx} = \frac{y^2 + z^2}{y^2 + x^2}$ will lead by a similar process to the integral

$$\tan^{-1} \frac{z}{y} - \tan^{-1} \frac{x}{y} = \psi(y).$$

(196.) Let us suppose next that the proposed differential equation contains two, three, or generally m , of the partial differential coefficients, for instance, $\frac{dx}{dx_1}, \frac{dx}{dx_2}, \dots, \frac{dx}{dx_m}$, its general form will be

$$X = \frac{dx}{dx_1} X_1 + \frac{dx}{dx_2} X_2 + \dots + \frac{dx}{dx_m} X_m.$$

If then $\phi_1 = c_1, \phi_2 = c_2, \dots, \phi_m = c_m$, represent a system of primitive equations satisfying the equations $X dx_1 - X_1 dx = 0, X dx_2 - X_2 dx = 0, \dots, X dx_m - X_m dx = 0$, or which is the same a system of m equations furnished by the proportions $dx : dx_1 : dx_2 : \dots : dx_m :: X : X_1 : X_2 : \dots : X_m$, the integral of the proposed equation will be $\pi(\phi_1, \phi_2, \phi_3, \dots, \phi_m, x_{m+1}, x_{m+2}, \dots, x_n) = 0$.

(197.) Let us now take some examples of the case in which the proposed equation contains all the partial differential coefficients, and first, when there are only three variables, one of which is considered as a function of

the two others. The form of the equation is then $X = \frac{dx}{dx_1} X_1 + \frac{dx}{dx_2} X_2$. The two equations to integrate are

those furnished by the proportions $dx : dx_1 : dx_2 :: X : X_1 : X_2$, and if we represent by $\phi_1 = c_1$, and $\phi_2 = c_2$, a system of two equations satisfying them, the required integral is $\pi(\phi_1, \phi_2) = 0$, or $\phi_1 = \psi(\phi_2)$.

The proportions $dx : dx_1 : dx_2 :: X : X_1 : X_2$ give the three equations

$$X dx_1 - X_1 dx = 0, \quad X dx_2 - X_2 dx = 0, \quad \text{and} \quad X_1 dx_2 - X_2 dx_1 = 0.$$

When it will happen that in two of these equations only the variables of which they contain the differentials will enter, for instance, in the first, the variables x and x_1 , and in the second the variables x and x_2 , it will not be necessary to descend to the second order to discover the values of ϕ_1 and ϕ_2 . It is obvious that these two equations may then be integrated separately by the rules previously given for the integration of differential equations of two variables of the first order.

If only one of the three equations were in the preceding case, if the last, for instance, contained only the variables x_2 and x_1 , whilst the three variables x, x_1, x_2 , entered each of the two others, the determination of ϕ_1 and ϕ_2 might still be effected by the integration of differential equations of two variables, and of the first order. For the integral of this last equation being found the value of x_2 might be determined in function of x_1 , and by substituting it in the first equation, it will reduce it to a differential equation of two variables which may be integrated separately.

When $X = 0$, this last method may always be used, whatever be even the number of variables, for then the two first equations are both reduced to $dx = 0$, and give $x = c_1$, in the last equation $X_1 dx_2 - X_2 dx_1 = 0$, therefore x may be considered as a constant quantity, and it may be integrated as a differential equation of two variables. Let the integral be represented by $\phi_2 = c_2$, and then the integral of the partial differential equation proposed will be $x = \psi(\phi_2)$.

Example 1. Let the proposed equation be $Xp + Yq = Z$, in which X designates a function of x only, Y a function of y , Z a function of z , and p and q the partial differential coefficients $\frac{dz}{dx}, \frac{dz}{dy}$. The two equations to integrate are $X dz - Z dx = 0, Y dz - Z dy = 0$. They may be integrated separately, and give

$$\int \frac{dz}{Z} - \int \frac{dx}{X} = c_1, \quad \int \frac{dz}{Z} - \int \frac{dy}{Y} = c_2,$$

hence the required integral is

$$\int \frac{dz}{Z} - \int \frac{dx}{X} = \psi \left(\int \frac{dz}{Z} - \int \frac{dy}{Y} \right).$$

Example 2. Let the equation be $px + qy = nz$, p, q designating the same quantities as in the preceding example. The two equations are $x dz - nz dx = 0, y dz - nz dy = 0$, which may be integrated separately.

The integrals are $\frac{z}{x^n} = c_1, \frac{z}{y^n} = c_2$, and therefore the required integral is $\frac{z}{x^n} = \psi \left(\frac{z}{y^n} \right)$, which may easily be

transformed into $z = x^n \psi \left(\frac{y}{x} \right)$, which shows that z is equal to any homogeneous function of x and y . This

result might have been foreseen easily, for the equation from which we have derived it, is the expression of a property of homogeneous functions which has been proved before.

Example 3. Let $px + qz + y = 0$ be the proposed equation. The equations to be integrated are two of the three, $x dz + y dx = 0, z dz + y dy = 0$, and $x dy - z dx = 0$. The second equation is the only one which can be integrated as a differential equation of two variables. It leads to $z^2 + y^2 = a^2$, a^2 being the arbitrary constant. Substituting then the value of y derived from this in the first equation $x dz + y dx = 0$, it becomes $x dz + dx \sqrt{a^2 - z^2} = 0$, which is a differential equation of two variables. Integrating, we find,

$\sin^{-1} \frac{z}{a} + lx = lc_2$, or $xe \sin^{-1} \frac{z}{a} = c_2$, and in substituting for the constant a its value $\sqrt{z^2 + y^2}$, we get

$xe \sin^{-1} \frac{z}{\sqrt{z^2 + y^2}} = c_2$. The integral of $px + qz + y = 0$ is therefore $xe \sin^{-1} \frac{z}{\sqrt{z^2 + y^2}} = \psi(y^2 + z^2)$.

Example 4. Let $(y - bz)p - (x - az)q = bx - ay$ be the proposed equation. We have the three equations

$$(y - bz) dz - (bx - ay) dx = 0, \quad (x - az) dz + (bx - ay) dy = 0, \quad (y - bz) dy + (x - az) dx = 0.$$

Each of these equations contains the three variables x, y, z , and therefore it seems, at first, that in order to integrate any two of them, it is necessary to descend to the second order. This, however, may be avoided, for by substituting the value of z taken in the last equation in either of the two first, we get

Integral
Calculus.

$$dz + a dx + b dy = 0,$$

and by substituting in the last for $a dx + b dy$ its value $-dz$, derived from this, we get

$$x dx + y dy + z dz = 0.$$

The two equations we have just obtained, may therefore be taken instead of any two of the equations above. They are obviously satisfied by the two primitive equations

$$z + ax + by = c_1, \quad x^2 + y^2 + z^2 = c_2.$$

Therefore, the integral of the proposed equation is

$$x^2 + y^2 + z^2 = \psi(z + ax + by).$$

(198.) When the proposed equation is homogeneous with respect to the variables, the integration may always be made to depend upon that of an equation of two variables. Let $X = \frac{dx}{dx_1} X_1 + \frac{dx}{dx_2} X_2$ be the equation, and

make $x_1 = tx$, and $x_2 = ux$, the quantities X, X_1, X_2 will evidently assume the forms Yx^n, Y_1x^n, Y_2x^n , n being the sum of the dimensions of the variables in each term of the proposed equation. Hence the two equations $X dx_1 - X_1 dx = 0, X dx_2 - X_2 dx = 0$, become $(Yt - y_1) dx + Yx dt = 0, (Yu - Y_2) dx + Yx du = 0$,

and eliminating between these $\frac{dx}{x}$ we find $(Yt - y_1) du - (Yu - y_2) dt = 0$, an equation which contains

only t and u . This being integrated will give the value of t in function of u , which being substituted in one of the two equations $(Yt - y_1) dx + Yx dt = 0, (Yu - Y_2) dx + Yx du = 0$, will enable us to find the value of x , or the required integral.

As an example of this method, let the given equation be $pxz + qyz = xy$, the two equations to be integrated are $xz dz - xy dx = 0, yz dz - xy dy = 0$. Assuming $x = tz$, and $y = uz$, they become $(1 - ut) dz - uz dt = 0$,

and $(1 - ut) dz - tz du = 0$, and in eliminating between them $\frac{dz}{z}$ we find $t du - u dt = 0$, and, therefore,

$u = c_1 t$. Substituting this value in either of the two equations, we get $(1 - c_1^2) dz - c_1 t z dt = 0$, the integral of which is $z \sqrt{1 - c_1^2} = c_2$. But $t = \frac{x}{z}, \frac{u}{t} = c_1 = \frac{y}{x}$, therefore $\frac{y}{x} = c_1$, and $\sqrt{z^2 - xy} = c_2$, hence

the required integral is $\sqrt{z^2 - xy} = \psi\left(\frac{y}{x}\right)$.

(199.) Partial differential equations containing more than three variables, present various cases analogous to the preceding. We shall only give two examples.

First, let the proposed equation be

$$(x_2 + x_1) \frac{dx}{dx_3} + (x_3 + x_1) \frac{dx}{dx_2} + (x_2 + x_3) \frac{dx}{dx_1} = 0.$$

The equations to integrate are

$$dx = 0, \quad (x_2 + x_1) dx_2 = (x_3 + x_1) dx_3, \quad (x_2 + x_1) dx_1 = (x_2 + x_3) dx_3, \quad (x_3 + x_1) dx_1 = (x_2 + x_3) dx_2.$$

The first gives $x = c_1$, the others cannot be integrated separately, since they each contain more than two variables, but they may be transformed into others which lead immediately to primitive equations which satisfy them.

If we subtract the second from the first, we find $(x_2 + x_1)(dx_2 - dx_1) = (x_1 - x_2) dx_3$, and by adding them, and $(x_2 + x_1) dx_3$ to each side of the equation, we get $(x_2 + x_1)(dx_1 + dx_2 + dx_3) = 2 dx_3 (x_1 + x_2 + x_3)$.

Equalling the values of $\frac{dx_3}{x_2 + x_1}$, taken in each of these two last equations, we find

$$\frac{dx_2 - dx_1}{x_1 - x_2} = \frac{dx_1 + dx_2 + dx_3}{2(x_1 + x_2 + x_3)},$$

which is obviously satisfied by the primitive equation $(x_1 - x_2)^2 (x_1 + x_2 + x_3) = c_2$

Operating in the same manner on the two last equations to be integrated, we shall find

$$(x_3 - x_2)^2 (x_1 + x_2 + x_3) = c_3,$$

consequently the integral of the proposed equation is

$$\pi \{ z, (x_3 - x_2)^2 (x_1 + x_2 + x_3), (x_1 - x_2)^2 (x_1 + x_2 + x_3) \} = 0, \text{ or } z = \psi \{ (x_3 - x_2)^2 (x_1 + x_2 + x_3), (x_1 - x_2)^2 (x_1 + x_2 + x_3) \}.$$

Let, for the second example, the equation be

$$x_1 \frac{dx}{dx_1} + x_2 \frac{dx}{dx_2} + x_3 \frac{dx}{dx_3} + x_4 \frac{dx}{dx_4} = ax,$$

which contains five variables. The equations to integrate are

Part III.
Integral
Calculus.

Part III.

$$x_1 dx - ax dx_1 = 0, \quad x_2 dx - ax dx_2 = 0, \quad x_3 dx - ax dx_3 = 0, \quad x_4 dx - ax dx_4 = 0.$$

They may be integrated separately, and give

$$\frac{x}{x_1^a} = c_1, \quad \frac{x}{x_2^a} = c_2, \quad \frac{x}{x_3^a} = c_3, \quad \frac{x}{x_4^a} = c_4.$$

Instead of the three last equations we may take $\frac{x_2}{x_1} = b_2, \quad \frac{x_3}{x_1} = b_3, \quad \frac{x_4}{x_1} = b_4$, b_2, b_3, b_4 being arbitrary constants. Therefore the integral required is

$$x = x_1^a \psi \left(\frac{x_2}{x_1}, \frac{x_3}{x_1}, \frac{x_4}{x_1} \right).$$

That is to say, that x is an homogeneous function of the degree a of the four variables x_1, x_2, x_3, x_4 .

(200.) Hitherto we have only considered equations in which the partial differential coefficients entered in the first degree. Let us consider now an equation of a degree higher than the first, but still of the first order. Lagrange has given a method to reduce the integration of such an equation, between three variables, to the integration of a partial differential equation of the first degree between four variables. The determination of the arbitrary function, which enters in the integral, is made to depend on the integration of a total differential equation of the first order, and of the first degree, between three variables, by a system of two equations. This integration is always possible, and requires, in considering one of the variables as a constant, which is allowed, only the integration of a differential equation of the first order, and of the first degree, between two variables.

This may be generalized, and it may be proved that it is always possible to derive from a partial differential equation of the first order between $n+1$ variables, a system of partial differential equations of the first order, and of the first degree, which may be integrated by the preceding method. The determination of the arbitrary functions requires besides the integration of a total differential equation of the first order, between $2n-1$ variables by a system of n equations, or between $2n-2$ variables by a system of $n-1$ equations, in considering one of the variables as a constant quantity, which may always be done.

(201.) Let x be a function of $x_1, x_2, \dots, x_n$, and make $\frac{dx}{dx_1} = p_1, \quad \frac{dx}{dx_2} = p_2, \dots, \frac{dx}{dx_n} = p_n$. We shall

have for any integer κ and λ $\frac{d p_\kappa}{d x_\lambda} = \frac{d p_\lambda}{d x_\kappa}$. Let the proposed equation be

$$0 = \phi(x, x_1, x_2, \dots, x_n, p_1, p_2, \dots, p_n).$$

If we differentiate it with respect to x_1 , and if we substitute the values

$$\frac{dx}{dx_1} = p_1, \quad \frac{dp_2}{dx_1} = \frac{dp_1}{dx_2}, \quad \frac{dp_3}{dx_1} = \frac{dp_1}{dx_3}, \dots, \frac{dp_n}{dx_1} = \frac{dp_1}{dx_n},$$

we shall have

$$-p_1 \cdot \frac{d\phi}{dx} - \frac{d\phi}{dx_1} = \frac{d\phi}{dp_1} \cdot \frac{dp_1}{dx} + \frac{d\phi}{dp_2} \cdot \frac{dp_1}{dx_2} + \dots + \frac{d\phi}{dp_n} \cdot \frac{dp_1}{dx_n}.$$

Similar equations will be obtained in differentiating with respect to $x_2, x_3, \dots, x_n$. We have, besides, identically,

$$p_1 \frac{d\phi}{dp_1} + p_2 \frac{d\phi}{dp_2} + \dots + p_n \frac{d\phi}{dp_n} = \frac{d\phi}{dp_1} \cdot \frac{dx}{dx_1} + \frac{d\phi}{dp_2} \cdot \frac{dx}{dx_2} + \dots + \frac{d\phi}{dp_n} \cdot \frac{dx}{dx_n}.$$

Consequently, if we make

$$p_1 \frac{d\phi}{dp_1} + p_2 \frac{d\phi}{dp_2} + \dots + p_n \frac{d\phi}{dp_n} = P,$$

we shall have the $n+1$ following equations :

$$\left. \begin{aligned} P &= \frac{d\phi}{dp_1} \cdot \frac{dx}{dx_1} + \frac{d\phi}{dp_2} \cdot \frac{dx}{dx_2} + \dots + \frac{d\phi}{dp_n} \cdot \frac{dx}{dx_n} \\ -p_1 \frac{d\phi}{dx} - \frac{d\phi}{dx_1} &= \frac{d\phi}{dp_1} \cdot \frac{dp_1}{dx} + \frac{d\phi}{dp_2} \cdot \frac{dp_1}{dx_2} + \dots + \frac{d\phi}{dp_n} \cdot \frac{dp_1}{dx_n} \\ -p_2 \frac{d\phi}{dx} - \frac{d\phi}{dx_2} &= \frac{d\phi}{dp_1} \cdot \frac{dp_2}{dx_1} + \frac{d\phi}{dp_2} \cdot \frac{dp_2}{dx_2} + \dots + \frac{d\phi}{dp_n} \cdot \frac{dp_2}{dx_n} \\ &\dots \dots \dots \\ -p_n \frac{d\phi}{dx} - \frac{d\phi}{dx_n} &= \frac{d\phi}{dp_1} \cdot \frac{dp_n}{dx_1} + \frac{d\phi}{dp_2} \cdot \frac{dp_n}{dx_2} + \dots + \frac{d\phi}{dp_n} \cdot \frac{dp_n}{dx_n} \end{aligned} \right\} \quad (C)$$

These $n+1$ partial differential equations have the property of each containing only the partial differential

coefficients of the same variable, whilst the partial differential coefficients, relative to the same variable, in all the equations, have the same coefficients. These equations may, therefore, be integrated by means of the theorem demonstrated. (194.) To that effect we shall form the following $2n$ total differential equations: Part III.

$$\begin{aligned} P \frac{d x_1}{d x} &= \frac{d \phi}{d p_1}, & P \frac{d x_2}{d x} &= \frac{d \phi}{d p_2}, & \dots & P \frac{d x_n}{d x} &= \frac{d \phi}{d p_n}, \\ P \frac{d p_1}{d x} &= -p_1 \frac{d \phi}{d x} - \frac{d \phi}{d x_1}, & P \frac{d p_2}{d x} &= -p_2 \frac{d \phi}{d x} - \frac{d \phi}{d x_2}, & \dots & P \frac{d p_n}{d x} &= -p_n \frac{d \phi}{d x} - \frac{d \phi}{d x_n}. \end{aligned}$$

From these equations we derive, in multiplying the equations of the second line respectively by $\frac{d \phi}{d p_1}, \frac{d \phi}{d p_2},$

adding them, and substituting in the right side of the equation, for $p_1 \frac{d \phi}{d p_1} + p_2 \frac{d \phi}{d p_2} + \dots + p_n \frac{d \phi}{d p_n}$ its value P ,

$$\frac{d \phi}{d x} d x + \frac{d \phi}{d x_1} d x_1 + \frac{d \phi}{d x_2} d x_2 + \dots + \frac{d \phi}{d x_n} d x_n + \frac{d \phi}{d p_1} d p_1 + \frac{d \phi}{d p_2} d p_2 + \dots + \frac{d \phi}{d p_n} d p_n = 0,$$

which shows that the given equation $\phi = 0$ is one of the $2n$ integrals of these differential equations.

Let the $2n - 1$ others be

$$\phi_1 = c_1, \quad \phi_2 = c_2, \quad \dots \quad \phi_{2n-1} = c_{2n-1},$$

where $c_1, c_2, \dots, c_n$ are arbitrary constants, and $\phi_1, \phi_2, \dots$ functions which do not contain these constants. If then we designate by $\pi_1, \pi_2, \pi_3, \dots, \pi_n$, arbitrary functions of $\phi_1, \phi_2, \dots, \phi_n$, the integrals of the $n + 1$ equations will be

$$\phi = 0, \quad \pi_1 = 0, \quad \pi_2 = 0, \quad \pi_3 = 0, \quad \dots \quad \pi_n = 0.$$

(202.) The $n + 1$ equations (c) have been deduced from the given equation $\phi = 0$, in taking into consideration that the quantities $p_1, p_2, \dots, p_n$ are the partial differential coefficients of x . But we cannot conclude

reciprocally from this system of equations, that $p_1 = \frac{d x}{d x_1}, p_2 = \frac{d x}{d x_2}, \dots, p_n = \frac{d x}{d x_n}$. It is, therefore, neces-

sary to determine the n equations $\pi_1 = 0, \pi_2 = 0, \dots, \pi_n = 0$, so that they may lead to the values $p_1 = \frac{d x}{d x_1}, p_2 = \frac{d x}{d x_2}, \dots, p_n = \frac{d x}{d x_n}$, which may be included in the single equation

$$d x = p_1 d x_1 + p_2 d x_2 + \dots + p_n d x_n.$$

(203.) Since the problem is resolved by n equations, between the quantities $\phi_1, \phi_2, \dots, \phi_{2n-1}$, we may conclude that the equation

$$d x = p_1 d x_1 + p_2 d x_2 + \dots + p_n d x_n$$

may be transformed into another containing only the quantities $\phi_1, \phi_2, \dots, \phi_{2n-1}$. This proposition may also be demonstrated in a different manner.

Let us consider for that purpose $2n$ out of the $2n + 1$ quantities $x, x_1, x_2, \dots, x_n, p_1, p_2, \dots, p_n$, for instance all but x , as functions of that variable, and of the quantities $\phi_1, \phi_2, \dots, \phi_{2n-1}$. In this supposition the equation

$$d x = p_1 d x_1 + p_2 d x_2 + \dots + p_n d x_n$$

becomes

$$\begin{aligned} d x &= d x \left\{ p_1 \frac{d x_1}{d x} + p_2 \frac{d x_2}{d x} + \dots + p_n \frac{d x_n}{d x} \right\} \\ &+ d \phi_1 \left\{ p_1 \frac{d x_1}{d \phi_1} + p_2 \frac{d x_2}{d \phi_1} + \dots + p_n \frac{d x_n}{d \phi_1} \right\} \\ &+ d \phi_2 \left\{ p_1 \frac{d x_1}{d \phi_2} + p_2 \frac{d x_2}{d \phi_2} + \dots + p_n \frac{d x_n}{d \phi_2} \right\} \\ &\dots \dots \dots \\ &+ d \phi_{2n-1} \left\{ p_1 \frac{d x_1}{d \phi_{2n-1}} + p_2 \frac{d x_2}{d \phi_{2n-1}} + \dots + p_n \frac{d x_n}{d \phi_{2n-1}} \right\}. \end{aligned}$$

For the sake of brevity, we may write this value of $d x$ under the following form,

$$d x = K d x + P_1 d \phi_1 + P_2 d \phi_2 + \dots + P_{2n-1} d \phi_{2n-1}.$$

The partial differentials with respect to x may easily be found in considering that, to obtain them, we must suppose the quantities $\phi_1, \phi_2, \dots, \phi_{2n-1}$ to be constant. We shall have, therefore, for that case, the differential equations of (200.)

$$P d x_1 = \frac{d \phi}{d p_1} d x, \quad P d x_2 = \frac{d \phi}{d p_2} d x, \quad \dots \quad P d x_n = \frac{d \phi}{d p_n} d x,$$

Integral
Calculus.

$$P dp_1 = - \left\{ p_1 \frac{d\phi}{dx} + \frac{d\phi}{dx_1} \right\} dx \dots \dots P dp_n = - \left\{ p_n \frac{d\phi}{dx} + \frac{d\phi}{dx_n} \right\} dx$$

or

$$P = p_1 \frac{d\phi}{dp_1} + p_2 \frac{d\phi}{dp_2} + \dots \dots + p_n \frac{d\phi}{dp_n}.$$

We have, consequently,

$$\frac{P dx_1}{dx} = \frac{d\phi}{dp_1}, \quad \frac{P dx_2}{dx} = \frac{d\phi}{dp_2} \dots \dots \frac{P dx_n}{dx} = \frac{d\phi}{dp_n}.$$

$$\frac{P dx_1}{dx} = - \left\{ p_1 \frac{d\phi}{dx} + \frac{d\phi}{dx_1} \right\} \dots \dots \frac{P dx_n}{dx} = - \left\{ p_n \frac{d\phi}{dx} + \frac{d\phi}{dx_n} \right\}.$$

Therefore

$$K = p_1 \frac{dx_1}{dx} + p_2 \frac{dx_2}{dx} + \dots \dots + p_n \frac{dx_n}{dx} = 1.$$

 The equation $dx = K dx + P_1 d\phi_1 + P_2 d\phi_2 + \dots \dots + P_{2n-1} d\phi_{2n-1}$ is then reduced to

$$0 = P_1 d\phi_1 + P_2 d\phi_2 + \dots \dots + P_{2n-1} d\phi_{2n-1}.$$

 Now it may be proved that in $P_1, P_2, \dots \dots, P_{2n-1}$ the variable x can only enter as a common factor to all these quantities. For if we differentiate the equation

$$P_1 = p_1 \frac{dx_1}{d\phi_1} + p_2 \frac{dx_2}{d\phi_1} + \dots \dots + p_n \frac{dx_n}{d\phi_1}$$

 with respect to x , we find

$$\frac{dP_1}{dx} = d \cdot \frac{\left\{ p_1 \frac{dx_1}{dx} + p_2 \frac{dx_2}{dx} + \dots \dots + p_n \frac{dx_n}{dx} \right\}}{d\phi_1}$$

$$+ \frac{dp_1}{dx} \cdot \frac{dx_1}{d\phi_1} + \frac{dp_2}{dx} \frac{dx_2}{d\phi_1} + \dots \dots + \frac{dp_n}{dx} \cdot \frac{dx_n}{d\phi_1},$$

$$- \left\{ \frac{dp_1}{d\phi_1} \frac{dx_1}{dx} + \frac{dp_2}{d\phi_1} \frac{dx_2}{dx} + \dots \dots + \frac{dp_n}{d\phi_1} \cdot \frac{dx_n}{dx} \right\},$$

 the first line is equal to $\frac{dk}{d\phi_1}$, and is, consequently, equal to nothing, since $k = 1$; if in the two others we substitute the value of the partial differential with respect to x found (192.), we shall have

$$\frac{dP_1}{dx} = - \frac{d\phi}{dx} \frac{P_1}{P} - \frac{1}{P} \left\{ \frac{d\phi}{dx_1} \frac{dx_1}{d\phi_1} + \dots \dots + \frac{d\phi}{dx_n} \frac{dx_n}{d\phi_1} \right\} = - \frac{d\phi}{dx} \frac{P_1}{P},$$

$$+ \frac{d\phi}{dp_1} \frac{dp_1}{d\phi_1} + \dots \dots + \frac{d\phi}{dp_n} \frac{dp_n}{d\phi_1} \Bigg\} = - \frac{d\phi}{dx} \frac{P_1}{P},$$

 since the expression included between the brackets, and which is the complete differential of ϕ with respect to ϕ_1 , vanishes, because $\phi = 0$. We shall find in the same manner

$$\frac{dP_2}{dx} = - \frac{d\phi}{dx} \frac{P_2}{P} \dots \dots \frac{dP_{2n-1}}{dx} = - \frac{d\phi}{dx} \frac{P_{2n-1}}{P},$$

therefore

$$\frac{dP_1}{P_1 dx} = \frac{dP_2}{P_2 dx} \dots \dots = \frac{dP_{2n-1}}{P_{2n-1} dx} = - \frac{1}{P} \frac{d\phi}{dx}.$$

Integrating, we find

$$P_1 = F_1 e^{-\int \frac{1}{P} \frac{d\phi}{dx} dx}, \quad P_2 = F_2 e^{-\int \frac{1}{P} \frac{d\phi}{dx} dx} \dots \dots P_{2n-1} = F_{2n-1} e^{-\int \frac{1}{P} \frac{d\phi}{dx} dx},$$

 when $F_1, F_2, \dots \dots, F_{2n-1}$ do not contain x . Therefore, if we divide by $e^{-\int \frac{1}{P} \frac{d\phi}{dx} dx}$, the equation $dx = p_1 dx_1 + p_2 dx_2 + \dots \dots + p_n dx_n$ will be reduced to

$$0 = F_1 d\phi_1 + F_2 d\phi_2 + \dots \dots + F_{2n-1} d\phi_{2n-1},$$

 in which equation $F_1, F_2, \dots \dots, F_{2n-1}$ are functions of $\phi_1, \phi_2, \dots \dots, \phi_{2n-1}$ only. This last equation is now to be integrated by a system of n equations, and this can always be done.

(204.) The method of integrating an equation such as

$$0 = F_1 d\phi_1 + F_2 d\phi_2 + \dots \dots + F_{2n-1} d\phi_{2n-1},$$

 by a system of n equations, ought to find place here. But not to exceed our limits, we shall only consider the case of three variables.

 Let $F_1 d\phi_1 + F_2 d\phi_2 + F_3 d\phi_3 = 0$ be the proposed equation, in which it is not necessary that the conditions of integrability should be satisfied. If we consider ϕ_3 as a constant quantity $d\phi_3 = 0$, and the equation being reduced to $F_1 d\phi_1 + F_2 d\phi_2 = 0$ may be integrated as a function of two variables. Let $U = c$ represent that integral, in which, instead of the arbitrary constant c , we may put an arbitrary function of ϕ_3 , and then the integral

Integral Calculus. takes the form $U = \psi(\phi_3)$. If we differentiate it with respect to the three variables ϕ_1, ϕ_2, ϕ_3 , we find Part III.
 $\frac{dU}{d\phi_1} d\phi_1 + \frac{dU}{d\phi_2} d\phi_2 + \frac{dU}{d\phi_3} d\phi_3 = \psi'(\phi_3) d\phi_3$, which equation ought to agree with the proposed differential equation $F_1 d\phi_1 + F_2 d\phi_2 + F_3 d\phi_3 = 0$. Let μ be the factor by which the equation $F_1 d\phi_1 + F_2 d\phi_2 = 0$ ought to be multiplied to become an exact differential, then $\frac{dU}{d\phi_1} d\phi_1 + \frac{dU}{d\phi_2} d\phi_2 = \mu F_1 d\phi_1 + \mu F_2 d\phi_2$, or equal to $-\mu F_3 d\phi_3$, since by multiplying the proposed equation by μ , we get $\mu F_1 d\phi_1 + \mu F_2 d\phi_2 + \mu F_3 d\phi_3 = 0$. Substituting in the differential of $U = \psi(\phi_3)$ the value which has just been found for its two first terms, it becomes, after having been divided by $d\phi_3$, $\frac{dU}{d\phi_3} - \mu F_3 = \psi'(\phi_3)$. Consequently the system of the two equations

$$U = \psi(\phi_3), \quad \frac{dU}{d\phi_3} - \mu F_3 = \psi'(\phi_3),$$

will satisfy the proposed equation whatever be the form of the function ψ .

(205.) We may now apply the general method given (201.) (202.) (203.) to the integration of partial differential equations of the first order, and of a degree higher than the first. We shall take for first example the

equation $p_1 p_2 = x$, in which $p_1 = \frac{dx}{dx_1}$, $p_2 = \frac{dx}{dx_2}$. In this case, the quantity represented by P (201.) is equal to $2 p_1 p_2$, and the total differential equations of the same number are,

$$2 p_1 \frac{dx_1}{dx} = 1, \quad 2 p_2 \frac{dx_2}{dx} = 1, \quad 2 p_2 \frac{dp_1}{dx} = 1, \quad 2 p_1 \frac{dp_2}{dx} = 1.$$

These equations are easily integrated; the equations which satisfy them are clearly

$$p_2 - x_1 = c_1, \quad x_2 - p_1 = c_2, \quad \frac{p_2}{p_1} = c_3, \quad \text{and } p_1 p_2 = x.$$

From these we derive, in putting ϕ_1, ϕ_2, ϕ_3 , instead of c_1, c_2, c_3 ,

$$x_1 = -\phi_1 + \sqrt{\phi_3} x, \quad x_2 = \phi_2 + \frac{\sqrt{x}}{\phi_3}, \quad p_1 = \sqrt{\frac{x}{\phi_3}}, \quad p_2 = \sqrt{\phi_3} x.$$

Hence, since

$$\frac{dx_1}{d\phi_1} = -1, \quad \frac{dx_1}{d\phi_2} = 0, \quad \frac{dx_1}{d\phi_3} = \frac{\sqrt{x}}{2\sqrt{\phi_3}}, \quad \frac{dx_2}{d\phi_1} = 0, \quad \frac{dx_2}{d\phi_2} = 1, \quad \frac{dx_2}{d\phi_3} = -\frac{\sqrt{x}}{2\sqrt{\phi_3}},$$

the equation $P_1 d\phi_1 + P_2 d\phi_2 + P_3 d\phi_3 = 0$, or $F_1 d\phi_1 + F_2 d\phi_2 + F_3 d\phi_3 = 0$, will be simply

$$d\phi_1 - \phi_3 d\phi_2 = 0.$$

This integrated by the method given (203.) in considering first ϕ_1 as a constant quantity, will give the two equations

$$\phi_2 = \psi(\phi_1), \quad \frac{1}{\phi_3} = \psi'(\phi_1),$$

or, in substituting for ϕ_1, ϕ_2 , and ϕ_3 , their values,

$$x_2 - \frac{x}{p_2} = \psi(p_2 - x_1), \quad \frac{x}{p_2^2} = \psi'\left(\frac{p}{2} - x\right).$$

These equations conjointly satisfy the proposed equation $x = p_1 p_2$, and by assuming any particular value to ψ , and then eliminating p_2 , will give an equation between x, x_1 , and x_2 .

We shall take for the second and last example, the equation $p_1^2 + p_2^2 = 1$. Here we have $P = 2 p_1^2 + 2 p_2^2 = 2$, and the total differential equations to be integrated are

$$\frac{dx_1}{dx} = p_1, \quad \frac{dx_2}{dx} = p_2, \quad \frac{dp_1}{dx} = 0, \quad \frac{dp_2}{dx} = 0.$$

They are satisfied by the equations

$$x_1 = c_3 x + c_1, \quad x_2 = x \sqrt{1 - c_3^2} + c_2, \quad p_1 = c_3, \quad p_2 = \sqrt{1 - c_3^2}.$$

Hence

$$\frac{dx_1}{d\phi_1} = 1, \quad \frac{dx_1}{d\phi_2} = 0, \quad \frac{dx_1}{d\phi_3} = x, \quad \frac{dx_2}{d\phi_1} = 0, \quad \frac{dx_2}{d\phi_2} = 1, \quad \frac{dx_2}{d\phi_3} = -\frac{x\phi}{\sqrt{1 - \phi_3^2}},$$

and, therefore, the equation to be integrated is

$$\phi_3 d\phi_1 + \sqrt{1 - \phi_3^2} d\phi_2 = 0.$$

If we consider ϕ_3 as a constant quantity, the integral is represented by the two equations

$$\phi_3 \phi_1 + \sqrt{1 - \phi_3^2} \phi_2 = \psi(\phi_3), \quad \phi_1 - \frac{\phi_3 \phi_2}{\sqrt{1 - \phi_3^2}} = \psi'(\phi_3),$$

or in substituting for ϕ_1, ϕ_2, ϕ_3 , their values, we find for the required equations

$$p_1 x_1 - x + x \sqrt{1 - p_1^2} = \psi(p_1), \quad x_1 \sqrt{1 - p_1^2} - p_1 x_2 = \psi'(p_1).$$

(206.) We shall next consider partial differential equations of the second and higher orders.

A partial differential equation of the n^{th} order in its most general form ought to include the independent variables, the required function, and all its differential coefficients, from the first to the n^{th} order. No theorem relative to partial differential equations under this general form has hitherto been found. In some particular cases the difficulty may be reduced to the integration of differential equations of lower orders.

Equations between three variables of the form

$$F \left\{ x, y, \frac{d^n z}{d y^n}, \frac{d^{n+1} z}{d x d y^n}, \dots, \frac{d^{n+m} z}{d x^m d y^n} \right\} = 0,$$

may be reduced to the m^{th} order by assuming $\nu = \frac{d^n z}{d y^n}$, for then they become

$$F \left\{ x, y, \nu, \frac{d \nu}{d x}, \frac{d^2 \nu}{d x^2}, \dots, \frac{d^m \nu}{d x^m} \right\} = 0.$$

This equation may be considered as a differential equation between two variables ν and x , since all the differential coefficients relate to the variable x , and it may therefore be integrated in the supposition of y being a constant quantity, and consequently the m arbitrary constants contained in the integral replaced by m arbitrary functions of y . Having found by this process the value of ν , that of z will be obtained by means of the equation

$\frac{d^n z}{d y^n} = \nu$, in which x may be supposed to be a constant quantity, and in the integral of which to the n arbitrary

constants ought to be substituted n arbitrary functions of x .

(207.) Equations of the n^{th} order which include partial differential coefficients with respect to one variable only, may clearly be treated as differential equations of two variables. And the integral being obtained in that supposition, the arbitrary constants should be replaced by arbitrary functions of the variables, with respect to which no partial differential coefficient was to be found in the proposed differential equation.

The first method may be applied to the equation $\frac{d^2 z}{d x d y} + P \frac{d z}{d x} = Q$, where P and Q contain only the variables x and y .

If we make $\frac{d z}{d x} = \nu$, it becomes $\frac{d \nu}{d y} + P \nu = Q$, the integral of which is

$$\nu = e^{-\int P dy} \left(\int e^{\int P dy} \cdot Q dy + c \right).$$

Therefore $\frac{d z}{d x} = e^{-\int P dy} \left(\int e^{\int P dy} \cdot Q dy + \phi(x) \right)$; integrating this with respect to z and x alone, we find

$$z = \int dx e^{-\int P dy} \left\{ \int e^{\int P dy} Q dy + \phi(x) \right\} + \psi(y).$$

If $P = 0$, this value is reduced to

$$z = \int dx \int Q dy + \int dx \phi(x) + \psi(y),$$

or $z = \int dx \int Q dy +$ an arbitrary function of $x +$ an arbitrary function of y , a result the truth of which is obvious.

The second method may be applied to the equation $\frac{d^2 z}{d x^2} + P \frac{d z}{d x} = Q$, in which P and Q include x, y , and z .

The equation ought to be integrated as a differential equation of the second order, between the variables x and y , and instead of the two arbitrary constants, two arbitrary functions of y introduced. If $P = 0$, and Q contain only x and y , the integral is

$$z = \int dx \int Q dx + x \phi(y) + \psi(y).$$

(208.) We shall now explain by what process may be integrated a partial differential equation of the second order, of the form

$$\frac{d^2 z}{d x^2} + P \frac{d^2 z}{d x d y} + Q \frac{d^2 z}{d y^2} = R,$$

where P, Q , and R are supposed to be any function of $x, y, z, \frac{d z}{d x}$, and $\frac{d z}{d y}$.

Let $\frac{d z}{d x} = p, \frac{d z}{d y} = q, \frac{d^2 z}{d x^2} = r, \frac{d^2 z}{d x d y} = s$, and $\frac{d^2 z}{d y^2} = t$, the proposed equation will become

$$r + P s + Q t = R,$$

Integral
Calculus.

and we shall have also

$$dz = p dx + q dy, \quad dp = r dx + s dy, \quad dq = s dx + t dy.$$

Now, if we form the two systems of equations,

$$dy - k dx = 0, \quad k dp + Q dq - R k dx = 0, \quad \text{and} \quad dk - k' dx = 0, \quad k' dp + Q dq - R k' dx = 0,$$

where k and k' are the roots of the equation $k^2 - Pk + Q = 0$; if from either of the two above systems of equations we can deduce either separately, or by adding any multiple of one to any multiple of the other, two primitive equations $M = a$, $N = b$, then $N = \phi(M)$ will be a first integral of the proposed equation; the integral of this equation of the first order, determined by the ordinary process, will be the second or complete integral required.

(209.) To demonstrate the theorem just stated, it is necessary to prove that the proposed equation $r + Ps + Qt = R$, may be derived from the equation $N = \phi(M)$.

We have first, $dN = \phi'(M) dM$, and

$$dN = \frac{dN}{dx} dx + \frac{dN}{dy} dy + \frac{dN}{dp} dp + \frac{dN}{dq} dq + \frac{dN}{dz} dz,$$

$$dM = \frac{dM}{dx} dx + \frac{dM}{dy} dy + \frac{dM}{dp} dp + \frac{dM}{dq} dq + \frac{dM}{dz} dz.$$

Substituting for dy its value $k dx$, and for dz its value $p dx + q dy = p dx + q k dx$, we find

$$dN = \left\{ \frac{dN}{dx} + k \frac{dN}{dy} + p \frac{dN}{dz} + q k \frac{dN}{dz} \right\} dx + \frac{dN}{dp} dp + \frac{dN}{dq} dq,$$

$$dM = \left\{ \frac{dM}{dx} + k \frac{dM}{dy} + p \frac{dM}{dz} + q k \frac{dM}{dz} \right\} dx + \frac{dM}{dp} dp + \frac{dM}{dq} dq.$$

Taking the value of dq in the equation $k dp + Q dq - R k dx = 0$, and substituting it in the two preceding equations, we shall get

$$dN = \left\{ \frac{dN}{dx} + k \frac{dN}{dy} + p \frac{dN}{dz} + q k \frac{dN}{dz} + \frac{R k}{Q} \frac{dN}{dq} \right\} dx + \frac{\left(Q \frac{dN}{dp} - k \frac{dN}{dq} \right)}{Q} dp,$$

$$dM = \left\{ \frac{dM}{dx} + k \frac{dM}{dy} + p \frac{dM}{dz} + q k \frac{dM}{dz} + \frac{R k}{Q} \frac{dM}{dq} \right\} dx + \frac{\left(Q \frac{dM}{dp} - k \frac{dM}{dq} \right)}{Q} dp.$$

But since, by hypothesis, M and N are equal to constant quantities, their differentials are equal to nothing, and since, moreover, x and p are here considered as independent variables, the coefficients of dx and dp in the values of dN and dM are separately equal to nothing. Hence we have the four following equations:

$$Q \left(\frac{dN}{dx} + k \frac{dN}{dy} + p \frac{dN}{dz} + q k \frac{dN}{dz} \right) + R k \frac{dN}{dq} = 0, \quad Q \frac{dN}{dp} - k \frac{dN}{dq} = 0,$$

$$Q \left(\frac{dM}{dx} + k \frac{dM}{dy} + p \frac{dM}{dz} + q k \frac{dM}{dz} \right) + R k \frac{dM}{dq} = 0, \quad Q \frac{dM}{dp} - k \frac{dM}{dq} = 0.$$

If we take the values of $\frac{dN}{dx}$, $\frac{dM}{dx}$, $\frac{dN}{dp}$, and $\frac{dM}{dp}$, in these four equations, and substitute them in the

equation $dN = \phi'(M) dM$, or

$$\left(\frac{dN}{dx} dx + \frac{dN}{dy} dy + \frac{dN}{dp} dp + \frac{dN}{dq} dq + \frac{dN}{dz} dz \right) = \phi'(M) \left\{ \frac{dM}{dx} dx + \frac{dM}{dy} dy + \frac{dM}{dp} dp + \frac{dM}{dq} dq + \frac{dM}{dz} dz \right\},$$

we shall find for result, after substituting $p dx + q dy$ for dz ,

$$\left(\frac{dN}{dy} + q \frac{dN}{dz} \right) (dy - k dx) + \frac{1}{Q} \frac{dN}{dq} (k dp + Q dq - R k dx) = \phi'(M) \left\{ \left(\frac{dM}{dy} + q \frac{dM}{dz} \right) (dy - k dx) + \frac{1}{Q} \frac{dM}{dq} (k dp + Q dq - R k dx) \right\},$$

therefore

$$k dp + Q dq - R k dx = w (dy - k dx),$$

where

$$w = - \frac{\left(\frac{dN}{dy} + q \frac{dN}{dz} \right) - \phi'(M) \left(\frac{dM}{dy} + q \frac{dM}{dz} \right)}{\frac{1}{Q} \left(\frac{dN}{dq} - \phi'(M) \frac{dM}{dq} \right)}.$$

Part III.
Integral
Calculus.

Part III.

Substituting $r dx + s dy$ for dp , and $s dx + t dy$ for dq , we shall find an equation between the independent variables x and y , which will give the two equations

$$kr + Qs - Rk = -wk, \quad ks + Qt = w.$$

Eliminating w we obtain

$$kr + k^2s + Qs + Qkt - Rk = 0.$$

But we have $k^2 = Pk - Q$, substituting this value, we find

$$k(r + Ps + Qt - R) = 0, \quad \text{or } r + Ps + Qt - R = 0,$$

which is the proposed equation.

(210.) Let us take for example of this method the equation

$$\frac{d^2z}{dx^2} + \frac{2y}{x} \frac{dz}{dx} + \frac{y^2}{x^2} \frac{dz}{dy} = 0, \quad \text{or } r + \frac{2y}{x}s + \frac{y^2}{x^2}t = 0.$$

Here the two values of k are equal to one another, and we have only one system of two equations. They are

$$x dy - y dx = 0, \quad x dp + y dq = 0.$$

Integrating we find $\frac{y}{x} = c$, $p + \frac{y}{x}q = c'$, therefore the first integral of the proposed equation is $p + \frac{y}{x}q = \phi\left(\frac{y}{x}\right)$.

This partial differential equation of the first order may be integrated according to the process given, (194.) We shall have then to integrate the two equations

$$x dy - y dx = 0, \quad dz - dx \phi\left(\frac{y}{x}\right) = 0.$$

The first gives $\frac{y}{x} = c$, the second becomes $z - x \phi\left(\frac{y}{x}\right) = c'$, and the required integral is, therefore,

$$z = x \phi\left(\frac{y}{x}\right) + \psi\left(\frac{y}{x}\right).$$

(211.) The equation $A r + B s + C t = V$, in which A, B, C are constant quantities, and V a function of x and y only, is easily integrated by the same process. The two values of k are then given by the equation $A k^2 - B k + C = 0$. The two values of k are therefore constant, and if we represent them by k' and k'' , we shall have to integrate either of the two following systems of equations:

$$dy - k' dx = 0, \quad A k' dp + C dq - V k' dx = 0, \quad \text{and } dy - k'' dx = 0, \quad A k'' dp + C dq - V k'' dx = 0$$

They give

$$y - k' x = a, \quad A k' p + C q - k' \int V dx = b, \quad \text{and } y - k'' x = a', \quad A k'' p + C q - k'' \int V dx = b'$$

The integral $\int V dx$ depends only on one variable, since y may be eliminated by means of the relations $y - k' x = a$, or $y - k'' x = a'$. We thus obtain the first two integrals of the proposed equation,

$$A k' p + C q - k' \int V dx = \phi(y - k' x), \quad \text{and } A k'' p + C q - k'' \int V dx = \psi(y - k'' x).$$

Either of these equations being integrated will give the next integral.

To obtain the integral of the first, we must integrate the two equations

$$A k' dy - C dx = 0, \quad A k' dz - k' dx \int V dx - dx \phi(y - k' x) = 0.$$

The first gives $A k' y - C x = a$, and by substituting the value of y derived from this integral into the second

$$\text{equation, it becomes } A k' dz - k' dx \int V dx - dx \phi\left(\frac{C x + a}{A k'} - k' x\right) = 0, \quad \text{or } A k' dz - k' dx \int V dx -$$

$$\left(\frac{C}{A k'} - k'\right) dx \phi\left(\left(\frac{C}{A k'} - k'\right)x + \frac{a}{A k'}\right) = 0, \quad \text{for since } \phi \text{ is an arbitrary function, we may prefix to it the}$$

constant factor $\left(\frac{C}{A k'} - k'\right)$. Under this form the equation may be integrated, and it is obvious that the

integral of the last term will be an arbitrary function of $\left(\frac{C}{A k'} - k'\right)x + \frac{a}{A k'}$. We have thus $A k' z - k' \int dx \int V dx - \phi_1$

$$\int V dx - \phi_1\left(\left(\frac{C}{A k'} - k'\right)x + \frac{a}{A k'}\right) = b, \quad \text{or putting back for } a \text{ its value, } A k' z - k' \int dx \int V dx - \phi_1$$

$(y - k' x) = b$. The required integral is therefore

$$A k' z - k' \int dx \int V dx - \phi_1(y - k' x) = \psi_1(A k' y - C x).$$

But $C = A k' k''$, substituting this value, dividing both sides by $A k'$, and suppressing the constant factors of the arbitrary functions, we find

$$z = \frac{1}{A} \int dx \int V dx + \phi_1(y - k'x) + \psi_1(y - k''x).$$

In effecting the integrations indicated in this equation it is necessary to attend to the following remarks.

1. In determining the value of $\int V dx$, y should be replaced in V by $k'x + a$; and after the integration of $V dx$ has been effected, a should be replaced by $y - k'x$. Then, before effecting the integration of $dx \int V dx$, y should be replaced in $\int V dx$ by $\frac{cx + a}{A k'}$, or by $k''x + a'$, and after the integration has been effected, $y - k''x$ should be substituted for a' .

This method applied to the equation $\frac{d^2 z}{dx^2} = C^2 \frac{dz}{dy^2}$, or $r = C^2 t$, gives for the integral

$$z = \phi(y - Cx) + \psi(y + cx).$$

The same process applied to the equation $r + Bs + Ct = xy$, gives

$$z = \frac{1}{b} x^3 y + \frac{1}{4-b} (m' + m'') x^4 = \phi(y - m'x) + \psi(y - m''x),$$

where m' and m'' are the roots of the equation $m^2 - Bm + C = 0$.

(212.) The equations

$$s + Pp + Qq + \left\{ P Q + \frac{dP}{dx} \right\} z = V, \quad s + Pp + Qq + \left\{ P Q + \frac{dQ}{dy} \right\} z = V,$$

where P , Q , and V are functions of x and y only, may be integrated in making $\frac{dz}{dy} + Pz = v$, which gives

$\frac{dv}{dx} = \frac{d^2 z}{dx dy} + \frac{P dz}{dx} + \frac{dP}{dx} z = s + Pp + \frac{dP}{dx} z$, and, consequently, $\frac{dv}{dx} + Qq + PQz = V$, or $\frac{dv}{dx} + Qv = V$. This is a linear equation of the first order, and being integrated gives

$$v = e^{-\int Q dy} \left\{ \int e^{\int Q dy} V dx + c \right\} = \frac{dz}{dy} + Pz.$$

The same process being repeated on this last equation, we shall obtain the value of z with two arbitrary constants, one of which may be replaced by an arbitrary function of x , and the other by an arbitrary function of y .

(213.) Partial differential equations of the third and higher orders, in which the partial differential coefficients of the highest order enter only in the first degree, may be treated by a method analogous to that which has been used with those of the second order.

If, for instance, $A \frac{d^3 z}{dx^3} + B \frac{d^3 z}{dx^2 dy} + C \frac{d^3 z}{dx dy^2} + D \frac{d^3 z}{dy^3} = V$ is a partial differential equation of the third order, in which A , B , C , D , V are any functions of x , y , z , and of the partial differential coefficients of the second and first order, the following theorem may be proved.

If m be one of the roots of the equation $A m^3 - B m^2 + C m - D = 0$, and if $M = a$, $N = b$, be two primitive equations derived from the two equations

$$-m dx = 0, \quad A dr + (B - Am) ds + (C - Bm + Am^2) dt - V dx = 0 \dots \dots (1),$$

then $N = \phi(M)$ will be one of the first integrals of the proposed equation.

The same theorem may easily be extended to partial differential equations of the form

$$A \frac{d^n z}{dx^n} + B \frac{d^n z}{dx^{n-1} dy} + C \frac{d^n z}{dx^{n-2} dy^2} + \dots \dots + \frac{T d^n z}{dx dy^{n-1}} = V.$$

The integration of the equation will thus be reduced to that of two equations of a form analogous to equations (1.), and these can only be integrated simultaneously under certain conditions.

In the third order, for instance, the equations (1.) contain generally eight variables, namely, x , y , z , p , q , r , s , t , between which we have, besides, the three equations

$$dz = p dx + q dy, \quad dp = r dx + s dy, \quad dq = s dx + t dy.$$

If, therefore, we eliminate between these five equations as many variables as possible, the resulting equation will contain still four variables, and will not therefore be integrable in every case.

(214.) The preceding method may be applied with success in the case in which the coefficients A , B , C , &c. are constant; it leads generally to n first integrals, each containing an arbitrary function, which are themselves partial differential equations of the $(n-1)^{th}$ with constant coefficients, and accordingly may be treated in the same manner as the proposed equation, and by the repetition of the same process the general integral may be obtained.

When $V = 0$, the calculation is still simpler; but in that particular case it is easy to see that if $m_1, m_2, m_3, \dots, m_n$ are the n roots of the equation

$$A m^n - B m^{n-1} + C m^{n-2}, \text{ \&c. } = 0,$$

Integral Calculus. the general value of z will be

$$z = \phi(y - m_1 x) + \psi(y - m_2 x) + \dots \chi(y - m_n x).$$

For each of the values,

$$z = \phi(y - m_1 x), \quad z = \psi(y - m_2 x) \dots z = \chi(y - m_n x),$$

satisfies the proposed differential equation. This may easily be verified, since we have

$$\frac{d^n z}{dx^n} = \mp m_1^n \phi_n(y - m_1 x), \quad \frac{d^n z}{dx^{n-1} dy} = \pm m_1^{n-1} \phi_n(y - m_1 x), \quad \frac{d^n z}{dx^{n-2} dy^2} = \mp m_1^{n-2} \phi_n(y - m_1 x), \&c.,$$

where $\phi_n(y - m_1 x)$ designates the n^{th} differential coefficient of $\phi(y - m_1 x)$, and where the superior signs must be taken when n is an odd number, and the inferior signs when n is even. These values being substituted in the proposed equation, give

$$A m_1^n - B m_1^{n-1} + C m_1^{n-2} \&c. = 0,$$

which equation is satisfied, since m_1 is one of the roots of the equation

$$A m^n - B m^{n-1} + C m^{n-2} \&c. = 0.$$

When some of the roots of this last equation are equal to one another, the value of z obtained by this method does not contain n arbitrary functions, and seems to be less general than in the case in which all the roots are different.

Let $m_1 = m_2$, for instance, the two first terms of the value of z $\phi(y - m_1 x)$, and $\psi(y - m_2 x)$ become arbitrary functions of the same quantity. To avoid this difficulty, let us assume generally $m_2 = m_1 + h$, then

$$\psi(y - m_2 x) = \psi(y - m_1 x - hx) = \psi(y - m_1 x) - \frac{hx}{1} \psi'(y - m_1 x) + \frac{h^2 x^2}{1 \cdot 2} \psi''(y - m_1 x) - \&c. \psi' \psi'',$$

&c. being the first, second, and differential coefficients of $\psi(y - m_1 x)$. If we assume $-h \psi'(y - m_1 x) = \psi(y - m_1 x)$, we shall have $h^2 \psi''(y - m_1 x) = -h \psi_1'(y - m_1 x)$, consequently the two first terms of the value

$$\text{of } z \text{ will be } = \phi(y - m_1 x) + \psi(y - m_1 x) + x \psi_1(y - m_1 x) - \frac{h x^2}{1 \cdot 2} \psi_1'(y - m_1 x) + \&c. \text{ Assuming}$$

$\phi(y - m_1 x) + \psi(y - m_1 x) = \phi_1(y - m_1 x)$, and making $h = 0$, the two first terms of the value of z will become $\phi_1(y - m_1 x) + x \psi_1(y - m_1 x)$.

If three of the values of m were equal to each other, $m_1 = m_2 = m_3$, for instance, by a similar process it would be found that the three first terms of the value of z would be an arbitrary function of $y - m_1 x + x$, multiplied by another arbitrary function of the same quantity $+ x^2$ multiplied by another arbitrary function of the same quantity

(215.) Partial differential equations containing more than three variables, in which the differential coefficients of the highest order enter only in the first degree, may be treated in an analogous manner.

Let

$$A \frac{d^2 z}{du^2} + B \frac{d^2 z}{dx^2} + C \frac{d^2 z}{dy^2} + D \frac{d^2 z}{du dx} + E \frac{d^2 z}{du dy} + F \frac{d^2 z}{dx dy} = V$$

be a partial differential equation of the second order, containing four variables, A, B, C, D, E, F, V , being functions of the four variables u, x, y, z , and of the differential coefficients of the first order, we shall have

$$dz = \frac{dz}{du} du + \frac{dz}{dx} dx + \frac{dz}{dy} dy.$$

$$d \frac{dz}{du} = \frac{d^2 z}{du^2} du + \frac{d^2 z}{du dx} dx + \frac{d^2 z}{du dy} dy.$$

$$d \frac{dz}{dx} = \frac{d^2 z}{dx du} du + \frac{d^2 z}{dx^2} dx + \frac{d^2 z}{dx dy} dy.$$

$$d \frac{dz}{dy} = \frac{d^2 z}{dy du} du + \frac{d^2 z}{dy dx} dx + \frac{d^2 z}{dy^2} dy.$$

And if we make $\frac{dz}{du} = n$, $\frac{dz}{dx} = p$, $\frac{dz}{dy} = q$, we shall get

$$\frac{d^2 z}{du^2} = \frac{1}{du} \left(dn - \frac{d^2 z}{du dx} dx - \frac{d^2 z}{du dy} dy \right).$$

$$\frac{d^2 z}{dx^2} = \frac{1}{dx} \left(dp - \frac{d^2 z}{du dx} du - \frac{d^2 z}{dx dy} dy \right).$$

$$\frac{d^2 z}{dy^2} = \frac{1}{dy} \left(dq - \frac{d^2 z}{du dy} du - \frac{d^2 z}{dx dy} dx \right).$$

These values being substituted in the proposed equation, give

$$A d n d x d y + B d p d u d y + C d q d u d x - V d u d x d y = \begin{cases} \frac{d^2 z}{d u d x} (A d x^2 d y + B d u^2 d y - D d u d x d y); \\ + \frac{d^2 z}{d u d y} (A d x d y^2 + C d u^2 d x - E d u d x d y); \\ + \frac{d^2 z}{d x d y} (B d u d y^2 + C d u d x^2 - F d u d x d y); \end{cases}$$

assume, then,

$$\begin{aligned} A d x^2 d y + B d u^2 d y - D d u d x d y &= 0, & A d x d y^2 + C d u^2 d x - E d u d x d y &= 0, \\ B d u d y^2 + C d u d x^2 - F d u d x d y &= 0, & A d n d x d y + B d p d u d y + C d q d u d x - V d u d x d y &= 0. \end{aligned}$$

If we assume $d x = h d u$, $d y = k d u$, the three first of these equations will take the form

$$A h^2 - D h + B = 0, \quad A k^2 - E k + C = 0, \quad B k^2 - F h k + C h^2 = 0.$$

They only contain two unknown quantities, and therefore they will only agree when the equation resulting from the elimination of h and k between these three equations will be satisfied. This equation is

$$A F^2 + B E^2 + C D^2 = 4 A B C + D E F,$$

and when it will be satisfied, we shall have between the seven variables u, x, y, z, n, p, q , the following equations,

$$d x - h d u = 0, \quad d y - k d u = 0, \quad A h k d n + B k d p + C h d q - V h k d u = 0,$$

and it may be proved that if $L = a$, $M = b$, $N = c$, are three equations satisfying the preceding, the first integral of the proposed equation will be $N = \phi(L, M)$.

(216.) The integration of partial differential equations is sometimes affected by means of various transformations. The equation

$$R r + S s + T t + P p + Q q + N z = V,$$

where R, S, T, P, Q, N , and V , are functions of x and y , may always be reduced to the form

$$S_1 \frac{d^2 z}{d u d v} + P_1 \frac{d z}{d u} + Q_1 \frac{d z}{d v} + N_1 z = M_1.$$

For that purpose let us assume that x and y are functions of two new variables, u and v , then z will be a function of u and v , and we shall have

$$d u = \frac{d u}{d x} d x + \frac{d u}{d y} d y, \quad d v = \frac{d v}{d x} d x + \frac{d v}{d y} d y, \quad d z = \frac{d z}{d u} d u + \frac{d z}{d v} d v;$$

substituting in the last equation for $d u$ and $d v$, their values taken in the first, we find

$$d z = \left(\frac{d z}{d u} \frac{d u}{d x} + \frac{d z}{d v} \frac{d v}{d x} \right) d x + \left(\frac{d z}{d u} \frac{d u}{d y} + \frac{d z}{d v} \frac{d v}{d y} \right) d y,$$

and consequently,

$$p = \frac{d z}{d u} \frac{d u}{d x} + \frac{d z}{d v} \frac{d v}{d x}, \quad q = \frac{d z}{d u} \frac{d u}{d y} + \frac{d z}{d v} \frac{d v}{d y}.$$

Differentiating these values we get

$$\begin{aligned} r &= \frac{d^2 z}{d u^2} \cdot \frac{d u^2}{d x^2} + \frac{2 d^2 z}{d u d v} \frac{d u d v}{d x d x} + \frac{d^2 z}{d v^2} \frac{d v^2}{d x^2} + \frac{d z}{d u} \frac{d^2 u}{d x^2} + \frac{d z}{d v} \frac{d^2 v}{d x^2}, \\ s &= \frac{d^2 z}{d u^2} \frac{d u d u}{d x d y} + \frac{d^2 z}{d u d v} \frac{d u d v}{d x d y} + \frac{d^2 z}{d v^2} \frac{d v d v}{d x d y} + \frac{d z}{d u} \frac{d^2 u}{d x d y} + \frac{d z}{d v} \frac{d^2 v}{d x d y} + \frac{d^2 z}{d u d v} \frac{d u d v}{d y d x}, \\ t &= \frac{d^2 z}{d u^2} \frac{d u^2}{d y^2} + 2 \frac{d^2 z}{d u d v} \frac{d u d v}{d y d y} + \frac{d^2 z}{d v^2} \frac{d v^2}{d y^2} + \frac{d z}{d u} \frac{d^2 u}{d y^2} + \frac{d z}{d v} \frac{d^2 v}{d y^2}. \end{aligned}$$

These expressions being substituted in the equation

$$R r + S s + T t + P p + Q q + N z = M,$$

transform it into

$$\begin{aligned} &\left(R \frac{d u^2}{d x^2} + S \frac{d u d u}{d x d y} + T \frac{d u^2}{d y^2} \right) \frac{d^2 z}{d u^2} + \left(2 R \frac{d u d v}{d x d x} + S \left(\frac{d u d v}{d x d y} + \frac{d u d v}{d y d x} \right) + 2 T \frac{d u d v}{d y d y} \right) \frac{d^2 z}{d u d v} \\ &\quad + \left(R \frac{d v^2}{d x^2} + S \frac{d v d v}{d x d y} + T \frac{d v^2}{d y^2} \right) \frac{d^2 z}{d v^2} + N z \\ &+ \left(R \frac{d^2 u}{d x^2} + S \frac{d^2 u}{d x d y} + T \frac{d^2 u}{d y^2} + P \frac{d u}{d x} + Q \frac{d u}{d y} \right) \frac{d z}{d u} + \left(R \frac{d^2 v}{d x^2} + S \frac{d^2 v}{d x d y} + T \frac{d^2 v}{d y^2} + P \frac{d v}{d x} + Q \frac{d v}{d y} \right) \frac{d z}{d v} \end{aligned} = M$$

To simplify these equations we may suppose that u and v satisfy the two equations

$$\left. \begin{aligned} R \frac{d^2 u^2}{dx^2} + S \frac{du}{dx} \frac{du}{dy} + T \frac{du^2}{dy^2} &= 0 \\ R \frac{dv^2}{dx^2} + S \frac{dv}{dx} \frac{dv}{dy} + T \frac{dv^2}{dy^2} &= 0 \end{aligned} \right\} (a),$$

and then the equation will be reduced to the form

$$\frac{d^2 z}{du dv} + P_1 \frac{dz}{du} + Q_1 \frac{dz}{dv} + N_1 z = M_1.$$

The quantities S_1, P_1, Q_1, N_1 , and M_1 will be expressed in terms of u and v will have been determined by means of the equations (a). These equations become, by assuming $\frac{du}{dx} = m \frac{du}{dy}, \frac{dv}{dx} = n \frac{dv}{dy}$,

$$R m^2 + S m + T = 0, \quad R n^2 + S n + T = 0.$$

Hence m and n are the roots of one or the other of these two equations, and will only contain the variables x and y . Substituting then the values of $\frac{du}{dx}$ and $\frac{dv}{dx}$ in the values of du and dv written above, we shall have

$$du = \frac{du}{dy} (dy + m dx), \quad dv = \frac{dv}{dy} (dy + n dx).$$

The values of $\frac{du}{dy}, \frac{dv}{dy}$ are still undeterminate, and may be considered as the factors by which the quantities $dy + m dx, dy + n dx$, ought to be multiplied to become differentials of functions of two variables. Let U and V represent the integrals of these differentials, then $u = U, v = V$, and by means of these equations the values of x and y may be determined in functions of u and v .

(217.) There are two cases in which the preceding transformation does not succeed. 1. When the roots of the equation $R m^2 + S m + T = 0$ are equal, that is when $4RT = S^2$. Then the values of u and v are, $u = \int \frac{du}{dy} (dy + m dx), v = \int \frac{dv}{dy} (dy + m dx)$, and consequently the variables u and v cannot be considered as independent variables. In that case it will be sufficient to assume x to be a function of u and y , that is to suppose $v = y$ in the preceding formulæ. We shall find first,

$$p = \frac{dz}{du} \frac{du}{dx}, \quad q = \frac{dz}{du} \frac{du}{dy} + \frac{dz}{dy};$$

$\frac{dz}{dy}$ in the last equation being not equal to q , but to the differential coefficient of z with respect to y after the transformation, we shall have also

$$\begin{aligned} r &= \frac{d^2 z}{du^2} \frac{du^2}{dx^2} + \frac{dz}{du} \frac{d^2 u}{dx^2}, & s &= \frac{d^2 z}{du^2} \frac{du}{dx} \frac{du}{dy} + \frac{d^2 z}{du dy} \frac{du}{dx} + \frac{dz}{du} \frac{du}{dx} \frac{du}{dy}, \\ t &= \frac{d^2 z}{du^2} \frac{du^2}{dy^2} + 2 \frac{d^2 z}{du dy} \frac{du}{dy} + \frac{d^2 z}{dy^2} + \frac{dz}{du} \frac{d^2 u}{dy^2}. \end{aligned}$$

By means of these values, and observing besides that $\frac{du}{dx} = m \frac{du}{dy}$, and $R m^2 + S m + T = 0$, or, in the present case, $S m + 2T = 0$, the proposed equation will take the form

$$S_1 \frac{d^2 z}{dy^2} + Q_1 \frac{dz}{dy} + P_1 \frac{dz}{du} + N_1 z = M_1.$$

2. The above method does not succeed when $S = 0$ and $T = 0$, but in that case the proposed equation becomes

$$R r + P p + Q q + N z = M,$$

that is to say, is precisely of that form to which it was proposed to reduce it.

(218.) In the general case the integration is therefore reduced to that of an equation of the form

$$\frac{d^2 z}{du dv} + P_1 \frac{dz}{du} + Q_1 \frac{dz}{dv} + N_1 z = M_1,$$

supposing that the whole equation has been divided by the coefficient of the first term. The two first terms of

this equation are equal to $\frac{d \left(\frac{dz}{dv} + P_1 z \right)}{du} - z \frac{d P_1}{du}$, and therefore it may be put under the form

$$\frac{d\left(\frac{dz}{dv} + P_1 z\right)}{du} + Q_1 \left\{ \frac{dz}{dv} + \frac{1}{Q_1} \left(N_1 - \frac{dP_1}{du} \right) z \right\} = M_1,$$

and it will be reduced to the first order, if

$$\frac{1}{Q_1} \left(N_1 - \frac{dP_1}{du} \right) = P_1, \text{ or } N_1 - P_1 Q_1 - \frac{dP_1}{du} = 0,$$

for then, if we make $\frac{dz}{dv} + P_1 z = z'$, it will be changed into

$$\frac{dz'}{du} + Q_1 z' = M_1$$

(219.) If the condition $N_1 - P_1 Q_1 - \frac{dP_1}{du} = 0$ is not satisfied, let $N_1 - P_1 Q_1 - \frac{dP_1}{du} = a$, and the value of N_1 derived from this equation be substituted in the equation

$$\frac{d\left(\frac{dz}{dv} + P_1 z\right)}{du} + Q_1 \left\{ \frac{dz}{dv} + \frac{1}{Q_1} \left(N_1 - \frac{dP_1}{du} \right) z \right\} = M_1,$$

we shall have

$$\frac{d\left(\frac{dz}{dv} + P_1 z\right)}{du} + Q_1 \left\{ \frac{dz}{dv} + P_1 z + \frac{a}{Q_1} z \right\} = M_1,$$

and if we assume $\frac{dz}{dv} + P_1 z = z'$, the preceding equation will be changed into

$$\frac{dz'}{du} + Q_1 z' + a z = M_1.$$

If we take now the value of z in this equation, and form the value of $\frac{dz}{dv}$, we shall have by substitution in the equation $\frac{dz}{dv} + P_1 z = z'$,

$$\frac{d^2 z'}{du dv} + P_1' \frac{dz'}{du} + Q_1 \frac{dz'}{dv} + N_1' z' = M_1' \dots\dots (b).$$

Making, for the sake of brevity,

$$P_1 - \frac{1}{a} \frac{da}{dv} = P_1', \quad a - \frac{Q_1}{a} \frac{da}{dv} + \frac{dQ_1}{dv} + P_1 Q_1 = N_1', \quad \frac{dM_1}{dv} - \frac{M_1}{a} \frac{da}{dv} + P_1 M_1 = M_1'.$$

The equation (b) may then be treated by the same process as the proposed equation, in assuming

$$\frac{dz'}{dv} + P_1' z' = z'', \quad N' - P_1' Q_1' - \frac{dP_1'}{du} = a',$$

and we shall derive from these suppositions

$$\frac{dz''}{du} + Q_1 z'' + a' z' = M_1';$$

and this equation can easily be integrated when $a' = 0$. If a' be not equal to nothing, then z' should be eliminated between this last equation and the equation (b). The result of this elimination would be an equation such as

$$\frac{d^2 z''}{du dv} + P_1'' \frac{dz''}{du} + Q_1 \frac{dz''}{dv} + N_1'' z'' = M_1''.$$

The same process ought to be applied to this equation, and being continued we shall form successively the values of $a, a', a'', \&c.$ if any one of them should be found equal to nothing. The integral of the corresponding equation in $z', z'', \&c.$ is immediately found, and successively the values of all the variables which have been introduced, and at last that of z .

(220.) Another transformation, which may sometimes be employed with advantage, is the following. Let

$$R \frac{d^2 z}{dx^2} + S \frac{d^2 z}{dx dy} + T \frac{d^2 z}{dy^2} = 0$$

be an equation in which the coefficients R, S, T are functions of p and q only. Then this equation may always be transformed into another of the form

$$R \frac{d^2 v}{dq^2} - S \frac{d^2 v}{dp dq} + T \frac{d^2 v}{dp^2} = 0,$$

where R, S, T are the same quantities as in the proposed equation.

Let $x dp + y dq = dv$; since $dz = p dx + q dy$, we have, in integrating by parts, $z = pq + qy - \int x dp + y dq$, therefore, $v = px + qy - z$, $x = \frac{dv}{dp}$, $y = \frac{dv}{dq}$. It is sufficient to know the value of v to be able to determine that of z .

To express now the value of $\frac{d^2 z}{dx^2}$ in functions of the new variables, it is necessary to observe that $\frac{d^2 z}{dx^2} = \frac{dp}{dx}$, y being considered as a constant quantity, in which hypothesis $d \frac{dv}{dq} = 0$, or $\frac{d^2 v}{dp dq} dp + \frac{d^2 v}{dq^2} dq = 0$. We have also $dx = \frac{d^2 v}{dp^2} dp + \frac{d^2 v}{dp dq} dq$; eliminating dq , we shall find

$$dx = \left(\frac{d^2 v}{dp^2} - \frac{\left(\frac{d^2 v}{dp dq} \right)^2}{\frac{d^2 v}{dq^2}} \right) dp.$$

Hence $\frac{dx}{dp} = \frac{\frac{d^2 v}{dp^2} \frac{d^2 v}{dq^2} - \left(\frac{d^2 v}{dp dq} \right)^2}{\frac{d^2 v}{dq^2}}$, and, consequently, $\frac{dp}{dx} = \frac{d^2 z}{dx^2} = \frac{\frac{d^2 v}{dq^2}}{\frac{d^2 v}{dp^2} \frac{d^2 v}{dq^2} - \left(\frac{d^2 v}{dp dq} \right)^2}$.

By similar operations we shall obtain

$$\frac{dz}{dx dy} = \frac{\frac{d^2 v}{dp^2} \frac{d^2 v}{dq^2} - \left(\frac{d^2 v}{dp dq} \right)^2}{\frac{d^2 v}{dp^2} \frac{d^2 v}{dq^2} - \left(\frac{d^2 v}{dp dq} \right)^2}, \quad \frac{dz}{dy^2} = \frac{\frac{d^2 v}{dp^2}}{\frac{d^2 v}{dp^2} \frac{d^2 v}{dq^2} - \left(\frac{d^2 v}{dp dq} \right)^2}.$$

These values being substituted in the proposed equation, will transform it into

$$R \frac{d^2 v}{dq^2} - S \frac{d^2 v}{dp dq} + T \frac{d^2 v}{dp^2} = 0.$$

(221.) Partial differential equations of the second or higher orders, which contain the differential coefficients in a degree higher than the first, present still greater difficulties to be integrated.

Any equations which contain only the differential coefficients of the second order, the general form of which is $r = f(s, t)$, may be transformed into another equation of the same order, containing the differential coefficients only in the first degree. To prove it, we have $dp = r dx + s dy$, $dq = s dx + t dy$, from which we derive $p = rx + sy - \int (x dr + y ds)$, $q = sx + ty - \int (x ds + y dt)$. If next we consider x and y as functions

of s and t , and if we assume $x ds + y dt = dv$, we find $x = \frac{dv}{ds}$, $y = \frac{dv}{dt}$. But the proposed equation being

differentiated, gives $dr = S ds + T dt$; by means of this value the function $x dr + y ds$ becomes $(Sx + y) ds + T x dt$, and, as it must be an exact differential, since $p = rx + sy - \int (x dr + y ds)$, we shall have the

equation $\frac{d \cdot (sx + y)}{dt} = \frac{d \cdot Tx}{ds}$, which being developed gives

$$S \frac{dx}{dt} + \frac{dy}{dt} = T \frac{dx}{ds}.$$

Substituting in this the values of $\frac{dx}{dt}$, $\frac{dx}{ds}$, $\frac{dy}{dt}$, we shall have the transformed equation

$$\frac{d^2 v}{dt^2} + S \frac{d^2 v}{ds dt} - T \frac{d^2 v}{ds^2} = 0,$$

which is only of the first degree with respect to the function v , since S and T do not contain the variables s and t . When v will become known, we shall derive from it, first the values of x and y in s and t , and then we shall find

$$q = sx + ty - v, \quad p = rx + sy - \int (x dr + y ds), \quad z = px + qy - \int (x dp + y dq);$$

and the integrations which are indicated will depend only on the integration of functions of one variable.

(222.) The first integral of the equation $rt - s^2 = 0$ may easily be found. It may be put under the form

$\frac{r}{s} = \frac{s}{t}$. Assume each of these ratios equal to w . Then $r = ws$, $s = wt$, and therefore, $r dx = ws dx$,

$s dy = wt dy$. Adding these two last equations, we get $r dx + s dy = w(s dx + t dy)$, or $dp = w dq$, or for the first integral of the proposed equation, $p = \phi(q)$.

Integral
Calculus.

(223.) Generally a particular integral may be obtained, the partial differential equations have the form $P = (rt - s^2)^n Q$, in which P designates a function of the differential coefficients p, q, r, s, t , and homogeneous with respect to the three last, n any positive exponent, and Q any function of the variables x, y, z , and of all the differential coefficients, such, however, that the supposition $rt - s^2 = 0$ does not make it infinite. Part III.

Making first $rt - s^2 = 0$, which gives $q = \phi(p)$, the above equation is reduced to $P = 0$; and from $q = \phi(p)$ we derive $s = r\phi'(p)$, $t = s\phi'(p) = r\phi'(p)^2$. Substituting these values in the equation $P = 0$, the differential coefficient r will become a common factor of the left side of the equation, which is homogeneous with respect to r, s, t .

There will remain, therefore, an equation between $p, \phi(p)$, and $\phi'(p)$, or between $p, q, \frac{dq}{dp}$, which may be used to

find the relation between the coefficients p and q , from which, by integration, we shall get an equation between x, y, z , containing an arbitrary function, and an arbitrary constant, and which ought to be considered as a particular integral of the proposed differential equation.

This method applied to the equation $t + 2ps + (p^2 - c^2)r = 0$, in which $Q = 0$, gives, by the substitutions indicated above,

$$\{\phi'(p)^2 + 2p\phi'(p) + p^2 - c^2\}r = 0, \quad \text{or } dq^2 + 2pdq + (p^2 - c^2)dp = 0.$$

Taking the value of dq in this last equation, we find

$$dq = -(p \mp c)dp, \quad q = -\frac{1}{2}p^2 \pm cp + a.$$

Substituting this value in the equation $dz = pdx + qdy$, we shall get the following system of equations,

$$z = px + (a \pm cp - \frac{1}{2}p^2)y + \phi(p), \quad 0 = x \pm cy - py + \phi'(p),$$

which will furnish two particular integrals of the proposed equation according to the sign of the constant c , and in taking different arbitrary functions.

(224.) The integral of partial differential equations may be represented by an infinite series, when none of the preceding methods can be used.

If the differential equation have the form

$$Rr + Ss + Tt + Pp + Qq + Nz = 0,$$

and if the quantities R, S, T, P, Q, N , are constant, it is obvious that we shall satisfy it by taking $z = A e^{ax+\phi y}$, provided a and ϕ satisfy the equation

$$Ra^2 + Sa\phi + T\phi^2 + Pa + Q\phi + N = 0.$$

Thus A remains undetermined as well as one of the exponents a, ϕ . Therefore if we take for a a series of arbitrary values, $a, a', a'', \&c.$ and if we designate by b and c, b' and c', b'' and $c'', \&c.$ the corresponding values of ϕ , the sum of the particular values of z will give

$$z = A e^{ax+by} + A' e^{a'x+b'y} + A'' e^{a''x+b''y} + \&c. \\ + B e^{ax+cy} + B' e^{a'x+c'y} + B'' e^{a''x+c''y} + \&c.$$

If we suppose $a = m + n\sqrt{-1}, a' = m - n\sqrt{-1}$, which give $b = p + q\sqrt{-1}, b' = p - q\sqrt{-1}$, the two first terms of the expression of z may be put under the form

$$e^{mx+py} \{A_1 \cos(nx + qy) + A'_1 \sin(nx + qy)\},$$

and an infinite series of such terms may be taken for the value of z .

(225.) The Theorem of Taylor may also be used to obtain in a series, arranged according to the powers of one of the independent variables, functions which are given by partial differential equations.

If z represent the unknown function, x one of the independent variables, and $Z, \frac{dZ}{dx}, \frac{d^2Z}{dx^2}, \&c.$ what $z, \frac{dz}{dx}, \frac{d^2z}{dx^2}, \&c.$ become when x is made equal to nothing, we shall have

$$z = Z + \frac{dZ}{dx}x + \frac{d^2Z}{dx^2} \cdot \frac{x^2}{1 \cdot 2} + \frac{d^3Z}{dx^3} \cdot \frac{x^3}{1 \cdot 2 \cdot 3} + \&c.$$

If the proposed equation be of the m^{th} order, the value of $\frac{d^m z}{dx^m}$, will be given by the equation, and all the

differential coefficients of higher orders will be found by the repeated differentiation of $\frac{d^m z}{dx^m}$ with respect to x only.

In the series the coefficients of all the powers of x less than m will remain undetermined, and arbitrary functions of all the variables but x may be taken to represent them.

Let us apply this method to the equation $\frac{d^2 z}{dx^2} = c^2 \frac{dz}{dy^2}$, which we have already integrated. (211.) In this case

Integral
Calculus.

Part III.

the first two terms of the series z and $\frac{dz}{dx}$ remain undetermined, and for the others we have by successive differentiations of the value of $\frac{d^2 z}{dx^2}$,

$$\begin{aligned}\frac{d^3 z}{dx^3} &= c^2 \frac{d^3 z}{dx dy^2} = c^2 \frac{d^2 \frac{dz}{dx}}{dy^2}, & \frac{d^4 z}{dx^4} &= c^2 \frac{d^4 z}{dx^2 dy^2} = c^2 \frac{d^3 \frac{d^2 z}{dx^2}}{dy^2} = c^4 \frac{d^4 z}{dy^4}, \\ \frac{d^5 z}{dx^5} &= c^2 \frac{d^5 z}{dx^3 dy^2} = c^2 \frac{d^4 \frac{dz}{dx}}{dy^2} = c^4 \frac{d^4 \frac{dz}{dx}}{dy^4}, \text{ \&c.}\end{aligned}$$

Designating by $\phi(y)$ the value of z when $x = 0$, $\phi'(y)$, or the differential coefficient of that function with respect to y , will be the corresponding value of $\frac{dz}{dy}$; let in the same supposition $\psi(y)$ represent the value of $\frac{dz}{dx}$, and we shall have

$$\begin{aligned}z &= \phi(y) + \psi(y) \frac{x}{1} + c^2 \phi''(y) \frac{x^2}{1 \cdot 2} + c^2 \psi''(y) \frac{x^3}{1 \cdot 2 \cdot 3} + c^4 \phi^{iv}(y) \\ &\quad \frac{x^4}{1 \cdot 2 \cdot 3 \cdot 4} + c^4 \psi^{iv}(y) \frac{x^5}{1 \cdot 2 \cdot 3 \cdot 4 \cdot 5} + \text{\&c.}\end{aligned}$$

The same series may be derived from the complete integral of the proposed differential equation which has been given. (211.) We have found

$$z = \phi(y + cx) + \psi(y - cx).$$

Developing each of these functions by Taylor's Theorem, we find

$$\phi(y + cx) = \phi(y) + \frac{cx}{1} \phi'(y) + \frac{c^2 x^2}{1 \cdot 2} \phi''(y) + \frac{c^3 x^3}{1 \cdot 2 \cdot 3} \phi'''(y) + \text{\&c.}$$

$$\psi(y - cx) = \psi(y) - \frac{cx}{1} \psi'(y) + \frac{c^2 x^2}{1 \cdot 2} \psi''(y) - \frac{c^3 x^3}{1 \cdot 2 \cdot 3} \psi'''(y) + \text{\&c.}$$

Adding these values, and substituting $\phi(y)$ to $\phi(y) + \psi(y)$, and $\psi(y)$ to $c\{\phi'(y) - \psi'(y)\}$, we shall obtain precisely the same series as we have found above.

(226.) The method of indeterminate coefficients may also be used to find the developement of the required function according to the powers of the independent variables. One or two examples will be sufficient to illustrate this process.

Let $\frac{d^2 u}{dx^2} + \frac{d^2 u}{dy^2} + \frac{d^2 u}{dz^2} = 0$ be the proposed equation, and assume

$$u = u_0 + u_1 z + u_2 z^2 + u_3 z^3 + \text{\&c.},$$

where $u_0, u_1, u_2, \text{\&c.}$ are functions of x and y . This value being substituted in the proposed equation, gives

$$\frac{d^2 u_0}{dx^2} + \frac{d^2 u_0}{dy^2} + 2u_2 + \left(\frac{d^2 u_0}{dx^2} + \frac{d^2 u_0}{dy^2} + 2 \cdot 3 \cdot u_3\right)z + \left(\frac{d^2 u_2}{dx^2} + \frac{d^2 u_2}{dy^2} + 3 \cdot 4 \cdot u_4\right)z^2 + \text{\&c.} \dots = 0,$$

and consequently

$$u_2 = -\frac{1}{2} \left(\frac{d^2 u_0}{dx^2} + \frac{d^2 u_0}{dy^2} \right), \quad u_3 = -\frac{1}{2 \cdot 3} \left(\frac{d^2 u_1}{dx^2} + \frac{d^2 u_1}{dy^2} \right),$$

$$u_4 = -\frac{1}{3 \cdot 4} \left(\frac{d^2 u_2}{dx^2} + \frac{d^2 u_2}{dy^2} \right) = -\frac{1}{1 \cdot 2 \cdot 3 \cdot 4} \left(\frac{d^4 u_0}{dx^4} + 2 \frac{d^4 u_0}{dx^2 dy^2} + \frac{d^4 u_0}{dy^4} \right),$$

and finally

$$u = u_0 + \frac{u_1}{1} \cdot z - \left(\frac{d^2 u_0}{dx^2} + \frac{d^2 u_0}{dy^2} \right) \frac{z^2}{1 \cdot 2} + \left(\frac{d^4 u_0}{dx^4} + 2 \frac{d^4 u_0}{dx^2 dy^2} + \frac{d^4 u_0}{dy^4} \right) \frac{z^3}{1 \cdot 2 \cdot 3 \cdot 4} + \text{\&c.}$$

a series which contains two arbitrary functions u_0 and u_1 .

The equation $\frac{d^2 z}{dx^2} = \frac{dz}{dy}$, treated by the same process, in assuming

$$z = y_0 + y_1 x + y_2 x^2 + y_3 x^3 + \text{\&c.}$$

gives $y_2 = \frac{1}{1 \cdot 2} \frac{dy_0}{dy}, \quad y_3 = \frac{1}{2 \cdot 3} \frac{dy_1}{dy}, \quad y_4 = \frac{1}{3 \cdot 4} \frac{dy_2}{dy}, \quad y_5 = \frac{1}{4 \cdot 5} \frac{dy_3}{dy}, \text{\&c.}$

and consequently in making $y_0 = \phi(y)$ and $y_1 = \psi(y)$, we get

Integral
Calculus.

$$z = \phi(y) + \psi(y) \cdot x + \phi'(y) \cdot \frac{x^2}{1 \cdot 2} + \psi'(y) \cdot \frac{x^3}{1 \cdot 2 \cdot 3} + \phi''(y) \cdot \frac{x^4}{1 \cdot 2 \cdot 3 \cdot 4} + \psi''(y) \cdot \frac{x^5}{1 \cdot 2 \cdot 3 \cdot 4 \cdot 5} + \&c. \quad \text{Part III.}$$

This value of z contains two arbitrary constants, and therefore may be considered as the general integral. We may obtain by the same means the value of z in a series arranged according to the powers of y , and we shall find

$$z = \phi(x) + \phi'(x) \frac{y}{2} + \phi''(x) \cdot \frac{y^2}{1 \cdot 2} + \phi'''(x) \cdot \frac{y^3}{1 \cdot 2 \cdot 3} + \&c.$$

This integral is less general than the preceding for it contains only one arbitrary function. A similar reduction, in the number of arbitrary functions, must take place whenever the proposed equation does not contain at the same time the differential coefficients of the highest order with respect to each variable, since there remain fewer indeterminate terms in the series, arranged according to the powers of the variable with respect to which there has been a less number of differentiations. It may, moreover, easily be shown, in the last example, that the first value, obtained for z , may be transformed into another, identical with the second. For that purpose, let

$$\phi(y) = a + \beta \frac{y}{1} + \gamma \frac{y^2}{1 \cdot 2} + \delta \frac{y^3}{1 \cdot 2 \cdot 3} + \&c.$$

$$\psi(y) = a' + \beta' \frac{y}{1} + \gamma' \frac{y^2}{1 \cdot 2} + \delta' \frac{y^3}{1 \cdot 2 \cdot 3} + \&c.$$

Substituting these values of $\phi(y)$ and $\psi(y)$ in the value, and arranging the terms according to the powers of y , we shall find

$$\begin{aligned} z = & a + a'x + \beta \frac{x^2}{1 \cdot 2} + \beta' \frac{x^3}{1 \cdot 2 \cdot 3} + \gamma \frac{x^4}{1 \cdot 2 \cdot 3 \cdot 4} + \gamma' \frac{x^5}{1 \cdot 2 \cdot 3 \cdot 4 \cdot 5} + \&c. \\ & + \left\{ \beta + \beta' \frac{x}{1} + \gamma \frac{x^2}{1 \cdot 2} + \gamma' \frac{x^3}{1 \cdot 2 \cdot 3} + \delta \frac{x^4}{1 \cdot 2 \cdot 3 \cdot 4} + \delta' \frac{x^5}{1 \cdot 2 \cdot 3 \cdot 4 \cdot 5} + \&c. \right\} \frac{y}{1}, \\ & + \left\{ \gamma + \gamma' \frac{x}{1} + \delta \frac{x^2}{1 \cdot 2} + \delta' \frac{x^3}{1 \cdot 2 \cdot 3} + \&c. \right\} \frac{y^2}{1 \cdot 2}, \\ & + \&c. \end{aligned}$$

All the coefficients of x being undetermined, we may make

$$a + a' \frac{x}{1} + \beta \frac{x^2}{1 \cdot 2} + \beta' \frac{x^3}{1 \cdot 2 \cdot 3} + \gamma \frac{x^4}{1 \cdot 2 \cdot 3 \cdot 4} + \gamma' \frac{x^5}{1 \cdot 2 \cdot 3 \cdot 4 \cdot 5} + \&c. = \phi(x),$$

ϕ designating a new arbitrary function; we find then, that the coefficient of $\frac{y}{1}$ is equal to $\frac{d^2 \phi(x)}{dx^2}$, or $\phi''(x)$, that of $\frac{y^2}{1 \cdot 2}$ equal to $\frac{d^4 \phi(x)}{dx^4}$, or $\phi^{(4)}(x)$, and so on with the others, and therefore the value of z becomes precisely the same as we have found before.

(227.) When the differential coefficient of the highest order that enters the equation has not been taken with respect to one variable only, the developement of the required function contains, not only arbitrary functions, but also arbitrary constants introduced by the integration of a series of differential equations of two variables. Let, for instance, the proposed equation be

$$\frac{d^2 z}{dx dy} + a \frac{dz}{dx} + b \frac{dz}{dy} + cz = 0,$$

and let

$$z = y_0 + y_1 x + y_2 x^2 + y_3 x^3 + \&c.$$

Substituting this value in the proposed equation, and making separately equal to nothing, the coefficients of the different powers of y , we shall have, to determine the values of $y_1, y_2, \&c.$, the following equations:

$$\frac{dy_1}{dy} + a y_1 + \frac{1}{1} \left(b \frac{dy_0}{dy} + c y_0 \right) = 0, \quad \frac{dy_2}{dy} + a y_2 + \frac{1}{2} \left(b \frac{dy_1}{dy} + c y_1 \right) = 0,$$

$$\frac{dy_3}{dy} + a y_3 + \frac{1}{3} \left(b \frac{dy_2}{dy} + c y_2 \right) = 0, \&c.$$

The function y_0 remains alone arbitrary, but the integration of the above differential equations will introduce an infinite number of constants.

If we suppose $a = 0, b = 0, c = -1$, the proposed equation will become $\frac{d^2 z}{dx dy} = z$, and we shall find

$$y_1 = \int y_0 dy, \quad y_2 = \frac{1}{2} \int y_1 dy, \quad y_3 = \frac{1}{3} \int y_2 dy + \&c.,$$

so that if we write $\phi(y)$ instead of y_0 , we shall have

Part III.
Integral
Calculus.

Part III.

$$z = \phi(y) + \frac{x}{1} \int \phi(y) dy + \frac{x^2}{1 \cdot 2} \int^2 \phi(y) dy^2 + \frac{x^3}{1 \cdot 2 \cdot 3} \int^3 \phi(y) dy^3 + \&c.$$

It may be proved that, in this case, all the arbitrary constants to be added to the integrals which are indicated, may be replaced by an arbitrary function. For that purpose, let us change $\phi(y)$ into $\phi(y) + A$, $\int \phi(y) dy$ into $\int \phi(y) dy + Ay + B$, $\int^2 \phi(y) dy^2$ into $\int^2 \phi(y) dy^2 + \frac{1}{2} Ay^2 + By + C$, &c. The terms which are not under the sign $\int$ being collected, will form the following expression,

$$A + Bx + \frac{1}{2} Cx^2 + \&c. + (Ax + \frac{1}{2} Bx^2 + \&c.)y + \left(\frac{1}{2} Ax^2 + \&c.\right)y^2 + \&c.,$$

which is the same thing as

$$\psi(x) + \frac{y}{1} \int \psi(x) dx + \frac{y^2}{1 \cdot 2} \int^2 \psi(x) dx^2 + \&c.,$$

for we may assume $A + Bx + Cx^2 + \&c. = \psi(x)$.

The general integral of the proposed equation will be then

$$z = \phi(y) + \frac{x}{1} \int \phi(y) dy + \frac{x^2}{1 \cdot 2} \int^2 \phi(y) dy^2 + \&c. \\ + \psi(x) + \frac{y}{1} \int \psi(x) dx + \frac{y^2}{1 \cdot 2} \int^2 \psi(x) dx^2 + \&c.$$

(228.) An important remark is that there are partial differential equations, of an order higher than the first, which have no first integral. This arises from the form of the primitive equation, which is such that neither of the arbitrary functions can be eliminated without proceeding to differential equations involving differential coefficients of the same order as the equation to be integrated. An example of this may be seen in the equation $rx - tx - 2p = 0$, the integral of which is $z = \phi(y+x) + \psi(y-x) - x\{\phi'(y+x) - \psi'(y-x)\}$, and to eliminate the arbitrary functions, it is necessary to proceed to the second order.

There are also equations the integrals of which do not admit a number of arbitrary functions equal to the exponent of their order, or for which the number of arbitrary functions, when equal to the exponent of the order, may be reduced. Sometimes the number of arbitrary functions is different according to the finite or infinite form given to the integral. It appears, therefore, that there is not a complete analogy between the arbitrary functions which enter in the integrals of partial differential coefficients, and the constants of the integrals of differential equations of two variables, since the number of the first is not always equal to the exponent of the order of the proposed partial differential equation.

If $V = 0$ represent a differential equation between the three variables x, y, z , we have the six equations

$$V = 0, \quad \frac{dV}{dx} = 0, \quad \frac{dV}{dy} = 0, \quad \frac{d^2V}{dx^2} = 0, \quad \frac{d^3V}{dx dx dy} = 0, \quad \frac{d^2V}{dy^2} = 0;$$

and between these we can eliminate five quantities, so that a partial differential equation of the second order may result from the elimination of five quantities. Generally, it is easy to see that a partial differential equation of the

order n may result from the elimination of $\frac{(n+1)(n+2)}{2} - 1$ quantities in a primitive equation.

If we suppose, first, that the quantities eliminated are constant, and if we call *complete integral* the primitive equation which contains them, to distinguish it from the general integral including arbitrary constants, it follows clearly from what precedes, that the first integral ought to contain only two arbitrary constants, the second five, the third nine, &c. We may also infer from the preceding considerations that there exist partial differential equations of the second order, which cannot have complete first integrals; for an integral of that kind can only contain in general two constants more than the partial differential equation from which it is derived, therefore it would be necessary that the five constants which are to be eliminated should enter V in such a manner as to disappear in two groups, the one composed of three constants, and the other of two. We shall illustrate these considerations by an example.

Let $z = f(a, b, a', b', c') + ax + by + a'x^2 + b'xy + c'y^2$

f designating a given function. We shall get in differentiating

$$p = a + 2a'x + b'y, \quad q = b + b'x + 2c'y, \quad r = 2a', \quad s = b', \quad t = 2c';$$

taking in these equations the values of the five constants a, b, a', b', c' , to substitute them in the first, we shall have

$$z = px + qy - \frac{1}{2}(rx^2 + 2sxy + ty^2) + f(p - rx - 5y, q - ty - 5x, \frac{1}{2}r, 5, \frac{1}{2}t);$$

and in order that this equation might be derived from an equation of the first order containing only two arbitrary

Integral
Calculus.

constants, three must disappear at the same time by the first differentiation of the proposed equation. Now if we subtract from this equation the values of p and q , multiplied respectively by x and y , we find Part III.

$$z - px - qy = f(a, b, a', b', c') - (a'x^2 + b'xy + c'y^2);$$

a result which will satisfy the required condition, only when the function f will not contain a', b', c' . In that supposition the quantity $a'x^2 + b'xy + c'y^2$ may be eliminated, and the resulting equation

$$2z - px - qy = 2f(a, b) + \alpha x + \beta y,$$

containing two arbitrary constants only, would be the required first integral of

$$z = px + qy - \frac{1}{2}(rx^2 + 2sxy + ty^2) + f(p - rx - 5y, q - ty - 5x).$$

(229.) Hitherto there are no means to determine, in general, the *complete integrals* of partial differential equations. The connection between the *complete integral* and the *general integral* is very simple, however, in the case of partial differential equations of the first order, and the second may be always deduced from the first, by making one of the constants an arbitrary function of the other; thus

$$z = ax + by + a^2 + b^2$$

is the complete solution of $z = px + qy + p^2 + q^2$. If we make $b = \phi(a)$, we get $z = ax + y\phi(a) + a^2 + \phi(a)^2$ and $x + y\phi'(a) + 2a + 2\phi(a)\phi'(a) = 0$; a system of equations from which the *general integral* is determined.

In the second and higher orders the passage from the *complete integral* to the *general integral* presents greater difficulties, and therefore very little advantage can be derived for the determination of the general integral, from the knowledge of the complete integral, which, in some cases, can be determined very readily.

(230.) Partial differential equations admit also of *particular solutions*. When the complete integral is known, the particular solutions may easily be found by the general method which has been explained. Let $V = 0$ be the complete integral of a partial differential equation of the first order, and let a and b be the arbitrary constants, then the system

$$V = 0, \quad \frac{dV}{da} da + \frac{dV}{db} db = 0,$$

will be the possible methods of satisfying the proposed differential equation; if we determine the values of a and b

by the two equations $\frac{dV}{da} = 0, \quad \frac{dV}{db} = 0$. These values substituted for a and b in the equation $V = 0$ will

give an equation without arbitrary constants, which will be a particular solution. The same reasoning, and the same process, will apply to equations of higher orders, when the complete integral is known.

(231.) Let us now investigate the characters by means of which it may be ascertained whether a given solution of a partial differential equation is included in the general solution or not. Let $Z = 0$ be the proposed equation, $z = V$ the given solution, and let $z = F(x, y, \phi(P), \psi(Q))$ represent the general integral, ϕ and ψ designating two arbitrary functions. If $z = V$ be a solution included in the general integral, then $\phi(P)$ and $\psi(Q)$ can take particular forms $f(P), f_1(Q)$, which will transform the general expression into V . This expression may be written in the following manner,

$$z = F\{x, y, f(P) + \phi(P) - f(P), \quad f_1(Q) + \psi(Q) - f_1(Q)\}.$$

The functions $\phi(P) - f(P), \psi(Q) - f_1(Q)$ being arbitrary may be represented by $a\phi(P)$ and $a\psi(Q)$. If we develop afterwards according to the powers of a , the result will take the form

$$z = V + a^m V \phi(P)^m + a^n W \psi(Q)^n + \&c.$$

or, more simply, $z = V + au$, u containing as many arbitrary functions as the general integral, and becoming neither infinite, nor equal to nothing when $a = 0$. We have by differentiation

$$p = \frac{dV}{dx} + a \frac{du}{dx}, \quad q = \frac{dV}{dy} + a \frac{du}{dy}, \quad r = \frac{d^2V}{dx^2} + a \frac{d^2u}{dx^2}, \quad s = \frac{d^2V}{dx dy} + a \frac{d^2u}{dx dy}, \quad t = \frac{d^2V}{dy^2} + a \frac{d^2u}{dy^2}.$$

These values, and the value of $z = V + au$, being substituted in the proposed equation $Z = 0$, we shall obtain, in observing that by supposition $z = V$ satisfies that equation,

$$\left. \begin{aligned} \frac{dz}{dz} u + \frac{dz}{dp} \frac{du}{dx} + \frac{dz}{dq} \frac{du}{dy} \\ + \frac{dz}{dr} \frac{d^2u}{dx^2} + \frac{dz}{ds} \frac{d^2u}{dx dy} + \frac{dz}{dt} \frac{d^2u}{dy^2} + \&c. \end{aligned} \right\} = 0.$$

If this substitution had made

$$\frac{dz}{dp} = 0, \quad \frac{dz}{dq} = 0, \quad \frac{dz}{dr} = 0, \quad \frac{dz}{ds} = 0, \quad \frac{dz}{dt} = 0, \quad \&c.$$

Integral
Calculus.

Part III.

the above equation would be reduced to $\frac{dz}{dz}u = 0$, and could only be verified in making $u = 0$, and, therefore,

there would be no means to introduce arbitrary functions in the expression $z = V$, and, consequently, $z = V$ ought to be considered as a particular solution.

If the differential coefficients $\frac{dz}{dp}$ and $\frac{dz}{dq}$ did not become equal to nothing, then the value of u would be

determined by the partial differential equation

$$\frac{dz}{dz}u + \frac{dz}{dp} \cdot \frac{du}{dx} + \frac{dz}{dq} \frac{du}{dy} = 0.$$

This equation being of the first order, the value of u would contain only one arbitrary function.

The mode of extending this rule to partial differential equations of all orders is obvious. Hence in the case of equations of the first order, for instance, if $V = 0$ be the result of the elimination of p and q from the equations

$V = 0$, $\frac{dV}{dp} = 0$, $\frac{dV}{dq} = 0$, the factors of $V = 0$ which satisfy these equations will be particular solutions; and

a similar method is applicable to equations of higher orders.

Let us take as an example, the equation

$$z = px + qy + a\sqrt{1+p^2+q^2}.$$

Here $Z = z - px - qy - a\sqrt{1+p^2+q^2}$, $\frac{dz}{dz} = 1$, $\frac{dz}{dp} = x - \frac{ap}{\sqrt{1+p^2+q^2}}$, $\frac{dz}{dq} = y - \frac{aq}{\sqrt{1+p^2+q^2}}$

Eliminating p and q between these two last equations and the proposed, we find

$$x^2 + y^2 + z^2 = a^2,$$

which satisfies them, and is consequently a particular solution.

Let us take for a second example, the equation

$$r^2 - 2qr\left(p - \frac{z}{1+x}\right) + \left(p - \frac{z}{1+x}\right)y = 0,$$

it gives $\frac{dz}{dr} = r - q\left(p - \frac{z}{1+x}\right)$, and since it contains neither s nor t , it is sufficient to combine the equation

$r - q\left(p - \frac{z}{1+x}\right) = 0$ with the proposed to determine the particular solution. By these means we find

$p - \frac{z}{1+x} = 0$, from which we derive $r = \frac{p}{1+x} - \frac{z}{(1+x)^2} = \frac{1}{1+x}\left(p - \frac{z}{1+x}\right)$, and which, consequently,

satisfies $Z = 0$, and $\frac{dZ}{dr} = 0$. It is therefore the particular solution required. Integrating it, we find

$z = (1+x)\phi(y)$.

(232.) The arbitrary functions which enter into the integral of partial differential equations are to be determined in each case by the conditions of the questions which led to the differential equations, in a manner analogous to that used for the arbitrary constants. This determination belongs, therefore, rather to the applications of the Differential and Integral Calculus, to Geometry, and Mechanics, than to the exposition of the rules of that calculus. In many cases besides, the conditions to be satisfied lead to equations expressing relations between unknown functions, the solution of which belongs to another calculus. We shall, therefore, briefly examine here, in what manner the arbitrary functions may be determined in some simple cases.

First let the integral of a partial differential equation be $M\phi(V) = 1$, where M and V are known functions of x , y , and z , and $\phi(V)$ an arbitrary function of V . Suppose that it is known, from the conditions of the question, that, besides the relation just found, there exist between the three variables x , y , z , two other relations expressed by the equations $F(x, y, z) = 0$, and $F_1(x, y, z) = 0$. Assume $V = t$, and by this, and the two preceding equations, let x , y , z be determined as functions of t . This being done, substitute those values of x , y , z , in

M , and let the result which will be a function of t be T , then we shall have $T \cdot \phi(t) = 1$, or $\phi(t) = \frac{1}{T}$, and the form of ϕ will thus be determined.

Let us next consider a case in which there are two arbitrary functions to be determined. Suppose that the integral is

$$M\phi(V) + N\psi(V) = 1,$$

and that the variables x , y , z must satisfy besides the conditions expressed by the two systems of equations,

$$F(x, y, z) = 0, \quad F_1(x, y, z) = 0, \quad \text{and} \quad F_2(x, y, z) = 0, \quad F_3(x, y, z) = 0.$$

Integral
Calculus.

As before, let $V = t$, and by this and the first pair of equations, let the values of x, y, z be determined as functions of t , and their values substituted in M and N . Then if T and T_1 represent the values of M and N after that substitution Part III.

$$T\phi(t) + T_1\psi(t) = 1.$$

If we determine in the same manner the values of x, y, z , as functions of t , by means of the equation $V = t$ and $F_2(x, y, z) = 0$, $F_3(x, y, z) = 0$, we shall have, in substituting these new values in M and N , and calling T_2 and T_3 the results of the substitutions,

$$T_2\phi(t) + T_3\psi(t) = 1.$$

From this equation and the other $T\phi(t) + T_1\psi(t) = 1$, the values of $\phi(t)$ and $\psi(t)$ may be determined as explicit functions of t , and therefore their forms will be known.

This process may easily be generalized, and applied to integrals containing a greater number of arbitrary functions, provided their form be similar to those we have considered.

Very frequently the arbitrary functions entering the integrals of partial differential equations remain entirely undetermined. The integrals, in this case, point out general properties belonging to the whole class of functions of x and y , represented by z .

APPLICATIONS OF THE DIFFERENTIAL AND INTEGRAL CALCULUS.

(233.) The Differential and Integral Calculus may be applied with great advantage to numerous and important questions. For many problems indeed it would be extremely difficult to obtain a solution without making use of that calculus. The development of functions of one or more variables in series of terms, proceeding according to certain laws, forms one of its most useful applications. Part III

(234.) Let y be a function of x which does not become infinite for $x = 0$, and let it be proposed to develop it according to the integral powers of x . Let us assume

$$y = A + Bx + Cx^2 + Dx^3 + \&c.$$

The problem is to determine the values of the coefficients $A, B, C, D, \&c.$ For that purpose let us differentiate several times this equation, we shall find successively,

$$\begin{aligned} \frac{dy}{dx} &= B + 2Cx + 3Dx^2 + 4Ex^3 + \&c. & \frac{d^2y}{dx^2} &= 2C + 3 \cdot 2Dx + 4 \cdot 3Ex^2 + \&c. \\ \frac{d^3y}{dx^3} &= 3 \cdot 2 \cdot D + 4 \cdot 3 \cdot 2 \cdot Ex + \&c. & \frac{d^4y}{dx^4} &= 4 \cdot 3 \cdot 2 \cdot E + \&c. \\ &\&c. & &\&c. \end{aligned}$$

Hence if we suppose in each of these equations $x = 0$, we shall easily find the values of $A, B, C, D, \&c.$ Let $Y, Y', Y'', \&c.$ be respectively the values of $y, \frac{dy}{dx}, \frac{d^2y}{dx^2}, \&c.$ when $x = 0$, we shall have

$$A = Y, \quad B = \frac{Y'}{1}, \quad C = \frac{Y''}{1 \cdot 2}, \quad D = \frac{Y'''}{1 \cdot 2 \cdot 3}, \quad E = \frac{Y''''}{1 \cdot 2 \cdot 3 \cdot 4}, \quad \&c.$$

and, consequently,

$$y = Y + Y' \cdot \frac{x}{1} + Y'' \cdot \frac{x^2}{1 \cdot 2} + Y''' \cdot \frac{x^3}{1 \cdot 2 \cdot 3} + Y'''' \cdot \frac{x^4}{1 \cdot 2 \cdot 3 \cdot 4} + \&c.$$

This elegant expression of the development of a function of one variable in a series of terms arranged according to the powers of that variable, is known under the name of the *Theorem of Maclaurin*: it is of considerable use in the development of functions, though it does not always enable us to discover the general term of the resulting series.

(235.) More generally, it may be proved, in the same manner, that if $y = f(a + x)$ does not become infinite for $x = 0$, the development of y according to the integral powers of x will be

$$y = Y + Y' \frac{x}{1} + Y'' \frac{x^2}{1 \cdot 2} + Y''' \frac{x^3}{1 \cdot 2 \cdot 3} + Y'''' \frac{x^4}{1 \cdot 2 \cdot 3 \cdot 4} + \&c.$$

$Y, Y', Y'', Y''', \&c.$ being the values of $y, \frac{dy}{dx}, \frac{d^2y}{dx^2}, \&c.$ corresponding to $x = 0$, or which is exactly the same

thing, the values of $f(x), \frac{df(x)}{dx}, \frac{d^2f(x)}{dx^2}, \frac{d^3f(x)}{dx^3}, \&c.$ corresponding to $x = a$, so that the development of y may be written in the following manner,

$$y = f(a + x) = f(a) + \frac{df(a)}{da} \cdot x + \frac{d^2f(a)}{da^2} \cdot \frac{x^2}{1 \cdot 2} + \frac{d^3f(a)}{da^3} \cdot \frac{x^3}{1 \cdot 2 \cdot 3} + \&c.$$

This expression may also be deduced immediately from Taylor's Theorem.

The application of this method to particular cases does not present the least difficulty. We might easily make use of it to determine the developments of $a^x, \log(a + x), \sin x, \cos x, \&c.$ which have already been found by various means, (see (26.), (27.), (28.))

(236.) We shall take as examples the functions $\sin^{-1} x, \cos^{-1} x$, and $\tan^{-1} x$.

1. For the first we have

$$\begin{aligned} y &= \sin^{-1} x, & \frac{dy}{dx} &= (1 - x^2)^{-\frac{1}{2}}, & \frac{d^2y}{dx^2} &= x(1 - x^2)^{-\frac{3}{2}}, & \frac{d^3y}{dx^3} &= (1 - x^2)^{-\frac{3}{2}} + 3x^2(1 - x^2)^{-\frac{5}{2}}, \\ \frac{d^4y}{dx^4} &= 3 \cdot 3x(1 - x^2)^{-\frac{5}{2}} + 3 \cdot 5x^3(1 - x^2)^{-\frac{7}{2}}, & \frac{d^5y}{dx^5} &= 3 \cdot 3(1 - x^2)^{-\frac{5}{2}} + 3 \cdot 5 \cdot 6x^2(1 - x^2)^{-\frac{7}{2}} + 3 \cdot 5 \cdot 7x^4(1 - x^2)^{-\frac{9}{2}}, & \&c. \end{aligned}$$

Making $x = 0$, we shall find

$$Y = 0, \quad Y' = 1, \quad Y'' = 0, \quad Y''' = 1, \quad Y'''' = 0, \quad Y'''' = 3 \cdot 3, \quad \&c.$$

Integral
Calculus.

and, consequently,

$$y = \sin^{-1} x = x + \frac{x^3}{1.2.3} + \frac{3.3 x^5}{1.2.3.4.5} + \&c.$$

The general term of the series may be obtained by observing that $\frac{d^{n+1}y}{dx^{n+1}} = \frac{1}{dx^n} d^n (1-x^2)^{-\frac{1}{2}}$, and making use of the general formula given in *Example 6. (25.)* We shall find that the value of $d^n (1-x^2)^{-\frac{1}{2}}$ becomes equal to nothing by making $x=0$, whenever n is an odd number, and that when n is an even number it is reduced to

$$\frac{1.3.5.7 \dots (n-1)}{2.4.6.8 \dots n} n(n-1) \dots 1.$$

The general term $\frac{d^{n+1}y}{dx^{n+1}} \cdot \frac{x^{n+1}}{1.2 \dots n+1}$, will become then, putting for $\frac{d^{n+1}y}{dx^{n+1}}$ the value of $\frac{1}{dx^n} d^n (1-x^2)^{-\frac{1}{2}}$, which has just been found,

$$\frac{1.3.5.7 \dots (n-1) x^{n+1}}{2.4.6.8 \dots n(n+1)}.$$

It is obvious besides that $n+1$ will be an odd number. If then we write in the series $\sin y$ instead of x , we shall have

$$y = \sin y + \frac{(\sin y)^3}{2.3} + \frac{3.(\sin y)^5}{2.4.5} + \frac{3.5(\sin y)^7}{2.4.6.7} + \frac{3.5.7(\sin y)^9}{2.4.6.8.9} + \&c.$$

This series has been used by Newton to calculate the length of the circumference, the radius being 1. If we suppose y equal to a quadrant, we shall have $\sin y = 1$, and if we suppose y equal to an arc of 30° , we shall have $\sin y = \frac{1}{2}$. Substituting these numbers, we obtain the two series

$$\text{arc of } 90^\circ = 1 + \frac{1}{2.3} + \frac{3}{2.4.5} + \frac{3.5}{2.4.6.7} + \frac{3.5.7}{2.4.6.8.9} + \&c.$$

$$\text{arc of } 30^\circ = \frac{1}{2} + \frac{1}{2^4.3} + \frac{3}{2^6.4.5} + \frac{3.5}{2^8.4.6.7} + \frac{3.5.7}{2^{10}.4.6.8.9} + \&c.$$

The first being multiplied by 4, and the second by 12 will give the length of the circumference.

The developement of the arc in a series of terms arranged according to the powers of the cosine might be obtained by a similar process; but it is immediately found by substituting in the preceding series $\frac{\pi}{2} - y$ for y , and

observing that $\sin\left(\frac{\pi}{2} - y\right) = \cos y$. We get thus

$$y = \frac{\pi}{2} - \cos y - \frac{(\cos y)^3}{2.3} - \frac{3.(\cos y)^5}{2.4.5} - \frac{3.5(\cos y)^7}{2.4.6.7} - \frac{3.5.7(\cos y)^9}{2.4.6.8.9} - \&c.$$

Let $y = \tan^{-1} x$, we shall have by successive differentiations

$$\frac{dy}{dx} = (1+x^2)^{-1}, \quad \frac{d^2y}{dx^2} = -2x(1+x^2)^{-2}, \quad \frac{d^3y}{dx^3} = -2(1+x^2)^{-2} + 8x^2(1+x^2)^{-3},$$

$$\frac{d^4y}{dx^4} = 24x(1+x^2)^{-3} - 48x^3(1+x^2)^{-4}, \quad \frac{d^5y}{dx^5} = 24(1+x^2)^{-3} - 288x^2(1+x^2)^{-4} + 384x^4(1+x^2)^{-5}, \&c.$$

Making $x=0$, we find

$$Y=0, \quad Y=1, \quad Y''=0, \quad Y'''=-2, \quad Y^{IV}=0, \quad Y^V=2.3.4, \&c.$$

And we get therefore

$$y = \tan^{-1} x = x - \frac{x^3}{3} + \frac{x^5}{5} - \&c.$$

The law of the terms is very obvious, and if it were necessary, the general term might be obtained by referring to the general formula of *Example 6. (25.)* Substituting $\tan y$ for x , the series becomes

$$y = \tan y - \frac{(\tan y)^3}{3} + \frac{(\tan y)^5}{5} - \frac{(\tan y)^7}{7} + \&c.$$

(237.) The developement of $\tan x$ might be obtained by the same method, but it will be simpler to use another somewhat different, which will have besides the advantage to show how to proceed when the function to be developed is given implicitly by a differential equation.

Let $y = \tan x$, then $dx = \frac{dy}{1+y^2}$, and, consequently, $\frac{dy}{dx} = 1+y^2$; the value of $\frac{dy}{dx}$ depends then, in this case, upon y , and the differential coefficients, instead of being given explicitly in function of the independent variable, will be determined by means of each other. We shall have

$$\frac{dy}{dx} = 1+y^2, \quad \frac{d^2y}{dx^2} = 2y \frac{dy}{dx}, \quad \frac{d^3y}{dx^3} = 2 \frac{d^2y}{dx^2} + 2y \frac{d^2y}{dx^2}, \&c.$$

Integral
Calculus

To deduce from these equations the values of $Y, Y', Y'',$ &c. it is necessary to make $x = 0$ in each of them. Part III.
If we had not the equation between x and $y, y = \tan x$, the value of Y would remain indeterminate. Here we have $Y = 0$, and we shall find by means of this value

$$Y = 0, Y' = 1, Y'' = 0, Y''' = 2, Y^{iv} = 0, Y^v = 16, Y^vi = 0, Y^{vii} = 272, \&c.$$

and therefore

$$y = \tan x = \frac{x}{1} + \frac{2x^3}{1 \cdot 2 \cdot 3} + \frac{16x^5}{1 \cdot 2 \cdot 3 \cdot 4 \cdot 5} + \frac{272x^7}{1 \cdot 2 \cdot 3 \cdot 4 \cdot 5 \cdot 6 \cdot 7} + \&c.$$

In the same manner may be found the developement of $\sec x$. Let $y = \sec x$, we shall have $dx = \frac{dy}{y\sqrt{y^2-1}}$,

and $\frac{dy}{dx} = y\sqrt{y^2-1}$, or, raising both sides to the square, $\frac{dy^2}{dx^2} = y^4 - y^2$. Then, by successive differentiations,

we shall get

$$\begin{aligned} 2 \frac{dy}{dx} \cdot \frac{d^2y}{dx^2} &= 4y^3 \frac{dy}{dx} - 2y \frac{dy}{dx}, \text{ or } \frac{d^2y}{dx^2} = 2y^3 - y, \quad \frac{d^3y}{dx^3} = (6y^2 - 1) \frac{dy}{dx}, \quad \frac{d^4y}{dx^4} = (6y^2 - 1) \frac{d^2y}{dx^2} \\ &+ 12y \frac{dy}{dx} \cdot \frac{d^3y}{dx^3} = (6y^2 - 1) \frac{d^3y}{dx^3} + 36y \frac{d^2y}{dx^2} \cdot \frac{dy}{dx} + 12 \frac{dy}{dx} \frac{d^3y}{dx^3}, \quad \frac{d^5y}{dx^5} = (6y^2 - 1) \frac{d^4y}{dx^4} + 48y \frac{d^3y}{dx^3} \cdot \frac{dy}{dx} \\ &+ 72 \frac{d^2y}{dx^2} \cdot \frac{d^3y}{dx^3} + 36y \left(\frac{d^2y}{dx^2} \right)^2 \&c. \end{aligned}$$

Hence, making $x = 0$, and observing that in that supposition $y = 1$, and $\frac{dy}{dx} = 0$ or $Y' = 0$, we have

$$Y'' = 1, \quad Y''' = 0, \quad Y^{iv} = 5, \quad Y^v = 0, \quad Y^{vi} = 61, \&c.$$

and

$$y = \sec x = 1 + \frac{x^2}{1 \cdot 2} + \frac{5x^4}{1 \cdot 2 \cdot 3 \cdot 4} + \frac{61x^6}{1 \cdot 2 \cdot 3 \cdot 4 \cdot 5 \cdot 6} + \frac{1385x^8}{1 \cdot 2 \cdot 3 \cdot 4 \cdot 5 \cdot 6 \cdot 7 \cdot 8} + \frac{5021x^{10}}{1 \cdot 2 \cdot 3 \cdot 4 \cdot 5 \cdot 6 \cdot 7 \cdot 8 \cdot 9 \cdot 10} + \frac{2702765x^{12}}{1 \cdot 2 \cdot 3 \cdot 4 \cdot 5 \cdot 6 \cdot 7 \cdot 8 \cdot 9 \cdot 10 \cdot 11 \cdot 12} + \&c.$$

(238.) The same principles may be used with success to develop functions of several variables in series arranged according to the integral powers of these variables. Let, for instance, $u = f(x, y)$ represent a function of two variables x and y , and assume

$$\begin{aligned} u &= A + Bx + Dx^2 + Gx^3 + \&c. \\ &+ Cy + Exy + Hx^2y \\ &+ Fy^2 + Ixy^2 \\ &+ Ky^3. \end{aligned}$$

We shall have by successive differentiations, first with respect to x alone,

$$\begin{aligned} \frac{du}{dx} &= B + 2Dx + 3Gx^2, & \frac{d^2u}{dx^2} &= 2D + 6Gx, & \frac{d^3u}{dx^3} &= 6G, \&c. \\ &+ Ey + 2Hxy & & & & \\ &+ Ky & & & & \end{aligned}$$

which will give the values of A, B, D, G by making $x = 0$, and $y = 0$ in $u, \frac{du}{dx}, \frac{d^2u}{dx^2}, \frac{d^3u}{dx^3},$ &c. The same

values being substituted for x and y in the expressions of $\frac{du}{dy}, \frac{d^2u}{dy^2}, \frac{d^3u}{dy^3},$ &c. will give the values of $C, F, K,$ &c.

and the same substitutions being made in $\frac{d^2u}{dx dy}, \frac{d^3u}{dx^2 dy}, \frac{d^3u}{dx dy^2},$ &c. will determine the remaining coefficients $E, H, I,$ &c. Thus we shall find

$$\begin{aligned} f(x, y) &= u + \frac{1}{1} \left\{ \frac{du}{dx} x + \frac{du}{dy} y \right\} + \frac{1}{1 \cdot 2} \left\{ \frac{d^2u}{dx^2} x^2 + 2 \frac{d^2u}{dx dy} xy + \frac{d^2u}{dy^2} y^2 \right\} + \frac{1}{1 \cdot 2 \cdot 3} \left\{ \frac{d^3u}{dx^3} x^3 + 3 \frac{d^3u}{dx^2 dy} x^2 y \right. \\ &\quad \left. + 3 \frac{d^3u}{dx dy^2} xy^2 + \frac{d^3u}{dy^3} y^3 \right\} + \&c. \end{aligned}$$

Recollecting that in u , and in every differential coefficient, x and y are supposed to have been made equal to nothing.

It is easy to see that the same series will also represent the developement of $f(a+x, b+y)$, supposing that in u , and in every differential coefficient, a and b have been substituted for x and y . These results are also immediate consequences of Taylor's Theorem, extended to functions of several variables.

(239.) The developements known under the names of Lagrange's and Laplace's Theorems, are two of the most important applications of the Differential Calculus to the transformation of functions into series. We shall begin with the demonstration of the last of these two theorems, because the first may easily be deduced from it by a particular supposition. Part III.

Let $u = \psi(y)$ represent any function of y , let y be a function of the independent variable x , determined by the equation $y = F(a + x\phi(y))$, F and ϕ designating any function whatever, and let it be proposed to develop u in a series of terms containing the integral powers of x . For that purpose, according to Maclaurin's Theorem,

it is sufficient to find the values of u , $\frac{du}{dx}$, $\frac{d^2u}{dx^2}$, &c. for $x = 0$. To obtain them, let us differentiate the equation $y = F(a + x\phi(y))$ first with respect to x , and then with respect to a , we shall get

$$\frac{dy}{dx} = F'(a + x\phi(y)) \cdot \left\{ \phi(y) + x\phi'(y) \frac{dy}{dx} \right\}, \quad \frac{dy}{da} = F'(a + x\phi(y)) \cdot \left\{ 1 + x\phi'(y) \frac{dy}{da} \right\}$$

If we eliminate $F'(a + x\phi(y))$ between these two equations, we shall find after reductions

$$\frac{dy}{dx} - \phi(y) \frac{dy}{da} = 0;$$

but since u , or $\psi(y)$, contains only y , we shall have simply

$$\frac{du}{dx} = \psi'(y) \frac{dy}{dx}, \quad \frac{du}{da} = \psi'(y) \frac{dy}{da};$$

and hence, by the elimination of $\psi'(y)$,

$$\frac{du}{dx} \cdot \frac{dy}{da} - \frac{du}{da} \cdot \frac{dy}{dx} = 0;$$

substituting then for $\frac{dy}{dx}$ its value $\phi(y) \frac{dy}{da}$, and making, for the sake of simplicity, $\phi(y) = z$, we shall find

$$\frac{du}{dx} - z \frac{du}{da} = 0, \quad \text{or} \quad \frac{du}{dx} = z \frac{du}{da}.$$

Hence the value of $\frac{du}{dx}$ corresponding to $x = 0$ is the same as the value of $z \frac{du}{da}$ corresponding to the same value of x . If we differentiate now the preceding equation with respect to x , we shall have

$$\frac{d^2u}{dx^2} = \frac{d \cdot z \frac{du}{da}}{dx};$$

but the quantity $z \frac{du}{da} = \phi(y) \psi'(y) \frac{dy}{da}$, that is to say is equal to a certain function of y multiplied by $\frac{dy}{da}$, it may therefore be considered as the differential coefficient of a certain function of y , which we shall represent by u' , with respect to a , and we shall have

$$z \frac{du}{da} = \frac{du'}{da}, \quad \text{and consequently} \quad \frac{d^2u}{dx^2} = \frac{d \cdot \frac{du'}{da}}{dx} = \frac{d^2u'}{dx da} = \frac{d^2u'}{da dx} = \frac{d \cdot \frac{du'}{dx}}{da}.$$

Now since, u representing any function of y , we have found $\frac{du}{dx} = z \frac{du}{da}$, u' being also a function of y , we shall have likewise $\frac{du'}{dx} = z \frac{du'}{da}$. Substituting this value in the last expression we have found for $\frac{d^2u}{dx^2}$, we get

$$\frac{d^2u}{dx^2} = \frac{d \cdot z \frac{du'}{da}}{da} = \frac{d \cdot z^2 \frac{du}{da}}{da},$$

putting for $\frac{du}{da}$ its value $z \frac{du}{dx}$.

This last equation being differentiated with respect to x will give $\frac{d^3u}{dx^3} = \frac{d^2 z^2 \frac{du}{da}}{dx da}$; or making $z^2 \frac{du}{da} = \frac{du''}{da}$,

and inverting the order of differentiations $\frac{d^3u}{dx^3} = \frac{d^3u''}{da^2 dx} = \frac{d^2 \frac{du''}{dx}}{da^2}$; but u'' being a function of y , we have also

$$\frac{du''}{dx} = z \frac{du''}{da}, \quad \text{and consequently} \quad \frac{d^3u}{dx^3} = z^3 \frac{du''}{da^3}; \quad \text{therefore} \quad \frac{d^3u}{dx^3} = \frac{d^2 z^3 \frac{du}{da}}{da^3}.$$

And generally, if $\frac{d^{n-1}u}{dx^{n-1}} = \frac{d^{n-2} \cdot z^{n-1} \frac{du}{da}}{da^{n-2}}$, making $z^{n-1} \frac{du}{da} = \frac{du'' \dots (n-1)}{da}$, (where $(n-1)$ designates the number of accents and not an exponent), we shall find

$$\frac{d^n u}{dx^n} = \frac{d^n u'' \dots (n-1)}{dx da^{n-1}} = \frac{d^n u'' \dots (n-1)}{da^{n-1} dx}, \text{ and because}$$

$$\frac{d u'' \dots (n-1)}{dx} = z \frac{d u'' \dots (n-1)}{da} = z^n \frac{du}{da}, \text{ we have}$$

$$\frac{d^n u}{dx^n} = \frac{d^{n-1} z^n \frac{du}{da}}{da^{n-1}}.$$

This understood, we shall have, according to Maclaurin's Theorem,

$$u = U + z \frac{du}{da} \frac{x}{1} + \frac{d \cdot z^2 \frac{du}{da}}{da} \frac{x^2}{1 \cdot 2} + \frac{d^2 \cdot z^3 \frac{du}{da}}{da^2} \frac{x^3}{1 \cdot 2 \cdot 3} + \dots + \frac{d^{n-1} z^n \frac{du}{da}}{da^{n-1}} \frac{x^n}{1 \cdot 2 \cdot 3 \dots n},$$

x being supposed to be made equal to nothing in every coefficient, and U designating the value of u in the same supposition. When $x = 0$, the equation $y = F(a + x\phi(y))$ gives $y = F(a)$, and $\frac{dy}{da} = F'(a)$, values which ought to be substituted in z or $\phi(y)$, and in $\frac{du}{da}$, or $\psi'(y) \frac{dy}{da}$. In the particular case represented by the equation $y = a + x\phi(y)$, we have simply, when $x = 0$, $y = a$, $\frac{dy}{da} = 1$, and therefore $U, z, \frac{du}{da}$, will become respectively $\psi(a), \phi(a)$, and $\psi'(a)$, and, consequently, the developement of u arranged according to the powers of x will be simply

$$u = \psi(a) + \psi'(a) \phi(a) \frac{x}{1} + \frac{d \cdot \psi'(a) \phi(a)^2}{da} \frac{x^2}{1 \cdot 2} + \frac{d^2 \cdot \psi'(a) \phi(a)^3}{da^2} \frac{x^3}{1 \cdot 2 \cdot 3} + \dots + \frac{d^{n-1} \cdot \psi'(a) \phi(a)^n}{da^{n-1}} \frac{x^n}{1 \cdot 2 \dots n}.$$

(240.) Laplace has extended these researches to functions of any number of variables, analogous to that we have just considered. We shall only examine the case of two variables. Let u be any function of two quantities y and z determined by the two equations

$$y = F[a + t\phi(y, z)], \quad z = F_1[b + x\phi_1(y, z)],$$

F, F_1, ϕ and ϕ_1 designating any function whatever. It is obvious that y and z may be considered as functions of the four quantities a, t, b , and x . Let the first of the two equations above be differentiated with respect to each of these quantities, we shall find

$$\frac{dy}{da} = F'(a + t\phi) \left(1 + t \frac{d\phi}{da}\right), \quad \frac{dy}{dt} = F'(a + t\phi) \left(\phi + t \frac{d\phi}{dt}\right),$$

$$\frac{dy}{db} = F'(a + t\phi) \cdot t \frac{d\phi}{db}, \quad \frac{dy}{dx} = F'(a + t\phi) t \frac{d\phi}{dx},$$

where ϕ is written instead of $\phi(y, z)$; and, in the same manner, we shall write simply ϕ_1 instead of $\phi_1(y, z)$. It is also necessary to remember that the functions ϕ and ϕ_1 are not supposed to contain explicitly the quantities t and x . If in the preceding values we suppose $t = 0$ and $x = 0$, we find

$$\frac{dy}{da} = F'(a), \quad \frac{dy}{dt} = F'(a) \cdot \phi, \quad \frac{dy}{db} = 0, \quad \frac{dy}{dx} = 0.$$

In the same manner we shall find

$$\frac{dz}{da} = 0, \quad \frac{dz}{dt} = 0, \quad \frac{dz}{db} = F_1'(b), \quad \frac{dz}{dx} = F_1'(b) \phi_1,$$

and in the same supposition u will become a function of a and b alone, since then $y = F(a)$ and $z = F_1(b)$. Now, if we observe that u is an explicit function of y and z , and if we substitute for $\frac{dy}{dt}, \frac{dz}{dt}, \frac{dy}{dx}, \frac{dz}{dx}$, their values, we shall have

$$\frac{du}{dt} = \frac{du}{dy} \cdot \frac{dy}{dt} + \frac{du}{dz} \frac{dz}{dt} = \frac{du}{dy} F'(a) \phi, \quad \frac{du}{dx} = \frac{du}{dy} \frac{dy}{dx} + \frac{du}{dz} \frac{dz}{dx} = \frac{du}{dz} F_1'(b) \phi_1,$$

Integral
Calculus.

and because $F'(a) = \frac{dy}{da}$, and $F_1'(b) = \frac{dz}{db}$, we shall have, when $t = 0$ and $x = 0$,

$$\frac{du}{dt} = \frac{du}{dy} \frac{dy}{da} \cdot \phi = \frac{du}{da} \cdot \phi, \quad \frac{du}{dx} = \frac{du}{dz} \frac{dz}{db} \cdot \phi_1 = \frac{du}{db} \phi_1.$$

Let us suppose, for a moment, that the equation $z = F_1(b + x\phi_1)$ has been resolved with respect to z , and that this value of z has been substituted in the function u ; then this function will contain only y and x , and in the differentiations relative to t , it will be sufficient to take into consideration the first quantity y , since the second x is one of the independent variables, but if we substitute at the same time the value of z in the equation $y = F(a + t\phi)$, then the function ϕ , when we shall differentiate with respect to t , may be considered as containing only y ; therefore we shall have as in (239.)

$$\frac{d^m u}{dt^m} = \frac{d^{m-1} \cdot \phi^m \frac{du}{da}}{da^{m-1}},$$

and, consequently,

$$\frac{d^{m+n} u}{dt^m dx^n} = \frac{d^n \left(\frac{d^{m-1} \cdot \phi^m \frac{du}{da}}{da^{m-1}} \right)}{dx^n} = \frac{d^{m-1} \left(\frac{d^{n-1} \cdot \phi^m \frac{du}{da}}{dx^n} \right)}{da^{m-1}}.$$

It is clear that the developement of $d^n \cdot \phi^m \frac{du}{da}$, may be deduced from that of $d^n \phi \frac{du}{da}$, by substituting in it ϕ^m

to ϕ , $d \cdot \phi^m$ to $d\phi$, $d^2 \cdot \phi^m$ to $d^2\phi$, and so on; we may, therefore, write simply $\phi \frac{du}{da}$, instead of $\phi^m \frac{du}{da}$; and since this last quantity is equal to $\frac{du}{dt}$, when $t = 0$, we shall have

$$\frac{d^{m+n} u}{dt^m dx^n} = \frac{d^{m-1} \left(\frac{d^{n+1} u}{dx^n dt} \right)}{da^{m-1}}.$$

In a similar manner we shall have

$$\frac{d^n u}{dx^n} = \frac{d^{n-1} \cdot \phi_1^n \frac{du}{db}}{db^{n-1}}, \text{ which equation may be changed into } \frac{d^n u}{dx^n} = \frac{d^{n-1} \frac{du}{dx}}{db^{n-1}},$$

by writing ϕ_1 instead of ϕ_1^n , and substituting instead of $\phi_1 \frac{du}{db}$, its value $\frac{du}{dx}$, in the case where $x = 0$; but it will be necessary to replace ϕ_1 by ϕ_1^n in the result.

Let us substitute now this expression of $\frac{d^n u}{dx^n}$ in that of $\frac{d^{m+n} u}{dt^m dx^n}$, found above, and we shall find

$$\frac{d^{m+n} u}{dt^m dx^n} = \frac{d^{m+n-2} \left(\frac{d^2 u}{dt dx} \right)}{da^{m-1} db^{n-1}},$$

in which, it must not be forgotten, it is necessary to substitute ϕ^n for ϕ , ϕ_1^n for ϕ_1 , and after the differentiations to make $t = 0$ and $x = 0$.

The preceding transformations have enabled us to make the determination of the coefficient $\frac{d^{m+n} u}{dt^m dx^n}$ depend on that of the second order $\frac{d^2 u}{dt dx}$, and on differentiations relative to a and b , which present no difficulties when $t = 0$ and $x = 0$. It remains therefore only to determine the value of $\frac{d^2 u}{dt dx}$.

If we differentiate with respect to x , the equation $\frac{du}{dt} = \frac{du}{da} \phi$, we shall find

$$\frac{d^2 u}{dx dt} = \frac{d^2 u}{dx da} \phi + \frac{du}{da} \frac{d\phi}{dx};$$

and since we have $\frac{du}{dx} = \frac{du}{db} \phi_1$,

$$\frac{d^2 u}{dx dt} = \phi \frac{d \cdot \phi_1 \frac{du}{db}}{da} + \frac{du}{da} \frac{d\phi}{dx}.$$

Integral
Calculus.

 But ϕ representing, as well as u , any function whatever of y and z , there exists between $\frac{d\phi}{dx}$ and $\frac{d\phi}{db}$ the same Part III.

 relation as between $\frac{du}{dx}$ and $\frac{du}{db}$, therefore we shall have also $\frac{d\phi}{dx} = \phi_1 \frac{d\phi}{db}$, hence

$$\frac{d^2 u}{dx dt} = \phi \phi_1 \frac{d^2 u}{da db} + \phi \frac{d\phi_1}{da} \frac{du}{db} + \phi_1 \frac{d\phi}{db} \frac{du}{da},$$

 and since we must change ϕ into ϕ^m , and ϕ_1 into ϕ_1^n , we shall find

$$\frac{d^2 u}{dx dt} = \phi^m \phi_1^n \frac{d^2 u}{da db} + n \phi^m \phi_1^{n-1} \frac{d\phi_1}{da} \frac{du}{db} + m \phi^{m-1} \phi_1^n \frac{d\phi}{db} \frac{du}{da},$$

 when, it is well understood, ϕ and ϕ_1 as well as u will be reduced to functions of a and b , by putting instead of y and z their values, when $t = 0$, and $x = 0$. Having thus formed $\frac{d^2 u}{dx dt}$, which we shall represent by $U^{(m+n)}$,

we shall have for the general term of the developement of the proposed function

$$\frac{a^{m+n-2} U^{(m+n)}}{d a^{m-1} d b^{n-1}} \cdot \frac{t^m x^n}{1.2 \dots m.1.2 \dots n}.$$

 Each term will be obtained individually by taking for m and n all the integers 0, 1, 2, 3, &c.

 (241.) If in the last formulæ of (239.) we make $x = 1$, we shall have

$$y = a + \phi(y) \text{ and the series } \psi(y) = \psi(a) + \psi'(a) \phi(a) + \frac{1}{1.2} \frac{d\psi(a)}{da} \phi(a)^2 + \frac{1}{1.2.3} \frac{d^2 \psi(a)}{da^2} \phi(a)^3 + \&c.$$

which Lagrange obtained by way of induction, in developing the roots of literal algebraical equations.

 We shall propose for first example to find the expression of the n^{th} power of y , given by the equation $a - \beta y + \gamma y^m = 0$.

 This equation may be put under the form $y = \frac{a}{\beta} + \frac{\gamma}{\beta} y^m$, and if we compare it with $y = a + \phi(y)$, we have clearly

$$a = \frac{a}{\beta}, \quad \phi(y) = \frac{\gamma}{\beta} y^m, \quad \psi(y) = y^n.$$

 If we write, for the sake of brevity, a instead of $\frac{a}{\beta}$ we find

$$\phi(a) = a^m \frac{\gamma}{\beta}, \quad \psi(a) = a^n, \quad \psi'(a) \phi(a) = n a^{n+m-1} \frac{\gamma}{\beta}, \quad \psi'(a) \phi(a)^2 = n a^{n+2m-1} \frac{\gamma^2}{\beta^2}, \quad \psi'(a) \phi(a)^3 = n a^{n+3m-1} \frac{\gamma^3}{\beta^3}, \&c.$$

and, consequently

$$y^n = a^n + \frac{n}{1} a^{n+m-1} \frac{\gamma}{\beta} + \frac{n(n+2m-1)}{1.2} a^{n+2m-2} \frac{\gamma^2}{\beta^2} + \frac{n(n+3m-1)(n+3m-2)}{1.2.3} a^{n+3m-3} \frac{\gamma^3}{\beta^3} + \&c.$$

 or, substituting $\frac{a}{\beta}$ for a

$$y^n = \frac{a^n}{\beta^n} \left\{ 1 + \frac{n}{1} \frac{a^{m-1} \gamma}{\beta^m} + \frac{n(n+2m-1)}{1.2} \frac{a^{2m-2} \gamma^2}{\beta^{2m}} + \frac{n(n+3m-1)(n+3m-2)}{1.2.3} \frac{a^{3m-3} \gamma^3}{\beta^{3m}} + \&c. \right\}.$$

 The proposed equation ought to give, in general, as many values for y^n as it has roots; but the above developement expressing only one of these values it may be asked to which it corresponds. Lagrange has proved, generally, that a property of this series, when employed to express the root of an equation, is to be always equal to the least root. In the present case it is easy to verify the truth of this proposition, when $m = 2$. The equation is then $a - \beta y + \gamma y^2 = 0$, and the roots are

$$y = \frac{\beta \pm \sqrt{\beta^2 - 4a\gamma}}{2\gamma} = \frac{\beta}{2\gamma} \left\{ 1 \pm \sqrt{1 - \frac{4a\gamma}{\beta^2}} \right\}.$$

In the first place, we have

$$\left(1 - \frac{4a\gamma}{\beta^2} \right)^{\frac{1}{2}} = 1 - \frac{1}{2} \frac{4a\gamma}{\beta^2} - \frac{1}{2} \cdot \frac{1}{4} \frac{(4a\gamma)^2}{\beta^4} - \frac{1.1.3}{2.4.6} \frac{(4a\gamma)^3}{\beta^6} + \&c.$$

Hence

$$y = \frac{\beta}{2\gamma} \pm \frac{\beta}{2\gamma} \left\{ 1 - \frac{1}{2} \frac{4a\gamma}{\beta^2} - \frac{1}{2} \cdot \frac{1}{4} \frac{(4a\gamma)^2}{\beta^4} - \frac{1.1.3}{2.4.6} \frac{(4a\gamma)^3}{\beta^6} + \&c. \right\}$$

and if we take only the inferior sign, and make some numerical reductions, we find for the least root

$$y = \frac{a}{\beta} \left\{ 1 + \frac{a\gamma}{\beta^2} + \frac{2a^2\gamma^2}{\beta^4} + \&c. \right\}$$

 a series which is precisely identical with the general series found above for y^n , when we make in it $n = 1$ and $m = 2$.

Lagrange has shown, moreover, that by proper transformations of a proposed equation, when it is algebraical,

Integral
Calculus.

it is possible to derive from the above theorem the developement of each root. (See *Mémoires de l'Académie de Berlin*, 1768, et le *Traité de la Résolution des Equations Numériques*, note XI.) Part III.

(242.) From the theorems which have been demonstrated, we may easily deduce a general formula for the inversion of series. Let $z = a y + \beta y^2 + \gamma y^3 + \&c.$ be given, and let it be proposed to find the value of y in a series of terms arranged according to the powers of z . We shall first put the given equation under the form

$$\frac{z}{a} - y - \frac{\beta}{a} y^2 - \frac{\gamma}{a} y^3 + \&c. = 0,$$

and if then we compare it with the equation $a - y + \phi(y) = 0$, we have $a = \frac{z}{a}$, and $\phi(y) = -\frac{y^2}{a} (\beta + \gamma y + \delta y^2 + \&c.)$. Hence, if we put before the sign of differentiation the constant factor $-\frac{1}{a}$, which multiplies $y^2 (\beta + \gamma y + \delta y^2 + \&c.)$ we shall find

$$y^n = a^n - \frac{n}{1 \cdot a} a^{n+1} (\beta + \gamma a + \delta a^2 + \&c.) + \frac{n}{1 \cdot 2 \cdot a^2} d \frac{a^{n+2} (\beta + \gamma a + \delta a^2 + \&c.)}{d a} \\ + \frac{n}{1 \cdot 2 \cdot 3 \cdot a^3} d^2 \frac{a^{n+3} (\beta + \gamma a + \delta a^2 + \&c.)^2}{d a^2} + \&c.$$

And if we make $n = 1$, and perform the operations indicated, we shall find after reduction

$$y = \frac{1}{a} z - \frac{\beta}{a^2} z^2 + \left(\frac{2\beta^2 - a\gamma}{a^5} \right) z^3 - \left(\frac{5\beta^3 - 5a\beta\gamma + a^2\delta}{a^7} \right) z^4 \\ + \left(\frac{14\beta^4 - 21a\beta^2\gamma + 6a^2\beta\delta + 3a^2\gamma^2 - a^3\epsilon}{a^9} \right) z^5 + \&c.$$

(243.) Let us take for second example the equation

$$u + \frac{d u}{d x} h + \frac{d^2 u}{d x^2} \frac{h^2}{1 \cdot 2} + \frac{d^3 u}{d x^3} \frac{h^3}{1 \cdot 2 \cdot 3} + \&c. \dots = 0,$$

and let it be proposed to find an expression for h in terms of u , and its differential coefficients.

If we put $p, q, r, s, \&c.$ for the differential coefficients of u , and compare the equation with $a - y + \phi(y) = 0$, we find $a = -\frac{u}{p}$, and $\phi(y) = -\frac{1}{p} \left\{ q \frac{h^2}{1 \cdot 2} + r \frac{h^3}{1 \cdot 2 \cdot 3 \cdot 4} + \&c. \right\}$ and therefore we shall get

$$h = -\left\{ \frac{u}{p} + \frac{q}{p^2} \cdot \frac{u^2}{1 \cdot 2} + \left(\frac{3q^2 - pr}{p^5} \right) \frac{u^3}{1 \cdot 2 \cdot 3} + \left(\frac{3 \cdot 5 q^3 - 2 \cdot 5 p q r + p^2 s}{p^7} \right) \frac{u^4}{1 \cdot 2 \cdot 3 \cdot 4} + \&c. \right\}.$$

This reverted series, which is used in the resolution of numerical equations, may be put under a very elegant and remarkable form. If we make $A = -\frac{d x}{d u} = -\frac{1}{p}$, then

$$h = A u + \frac{A d A}{d x} \cdot \frac{u^2}{1 \cdot 2} + \frac{A d (A d A)}{d x^2} \frac{u^3}{1 \cdot 2 \cdot 3} + \frac{A d \{ A d (A d A) \}}{d x^3} \cdot \frac{u^4}{1 \cdot 2 \cdot 3 \cdot 4} + \&c.$$

To show the application of this to the resolution of numerical equations, let us suppose $u = x^4 - 2x^2 + 4x - 8$; we shall find by means of this series

$$h = -\left\{ \frac{1}{2^3 (x^3 - x + 1)} \cdot \frac{u}{1} + \frac{3x^2 - 1}{2^4 (x^3 - x + 1)^2} \frac{u^2}{1 \cdot 2} + \frac{(21x^4 - 12x^2 - 6x + 3)}{2^6 (x^3 - x + 1)^3} \frac{u^3}{1 \cdot 2 \cdot 3} + \&c. \right\};$$

if a be a root of the equation $u = 0$, and x be an approximate value of a , we shall find

$$a = x + h = x - \frac{1}{2^3 (x^3 - x + 1)} \cdot \frac{u}{1} - \frac{(3x^2 - 1)}{2^4 (x^3 - x + 1)^2} \frac{u^2}{1 \cdot 2} - \&c.$$

Thus if $x = \frac{3}{2}$, and therefore $u = -\frac{23}{16}$, we shall get $a = \frac{3}{2} + \frac{1}{8} - \frac{1}{64} + \frac{391}{135424} - \&c. = 1.61$ nearly.

If we substitute this new value of x , and confine ourselves to four terms of the series, as before, we shall find $a = 1.6117662$: and by a continuation of this process, the approximation may be carried to any required degree of accuracy.

(244.) These theorems possess especially great advantages with respect to equations involving transcendental functions. Let us take for example the equation $y = a + a \sin y$, which expresses a general relation of the first degree between an arc and its sine, and let it be proposed to find the developement of ly . The comparison between this equation and $a - y + \phi(y) = 0$ gives $\phi(y) = a \sin y$, and we have besides in this case $\psi(y) = ly$; therefore we shall find

$$ly = la + \frac{a}{1} \frac{\sin a}{a} + \frac{a^2}{1 \cdot 2} \frac{d \frac{(\sin a)^2}{a}}{d a} + \frac{a^3}{1 \cdot 2 \cdot 3} \frac{d^2 \frac{(\sin a)^3}{a}}{d a^2} + \&c.$$

Integral
Calculus.

In the same manner the equation $u = nt + e \sin u$, of so much use in Astronomy, gives, after substituting for the powers of the sines their values in function of the sines of the multiples of the arc, Part III.

$$u = nt + e \sin nt + \frac{e^2}{1.2.2} 2 \sin 2nt + \frac{e^3}{1.2.3.2^2} (3^2 \sin 3nt - 3 \sin nt) + \frac{e^4}{1.2.3.4.2^3} (4^3 \sin 4nt - 4 \cdot 2^3 \sin 2nt) + \&c.$$

(245.) Burmann has given on the developement of functions in series a very general theorem, from which that of Lagrange and a great many others may be deduced.

Let X designate any function of x , and let this last quantity be a function of u ; the problem to be resolved is to develop X according to the powers of u . If x were eliminated from X , then this quantity would be an explicit function of u , and Maclaurin's Theorem would give immediately

$$X = T + T' \frac{u}{1} + T'' \frac{u^2}{1.2} + T''' \frac{u^3}{1.2.3} + \&c.$$

a formula in which $T^{(n)} = \frac{d^n X}{d u^n}$ when u has been made equal to nothing after the differentiations.

The theorem of Burmann has for its object to transform the above formula into

$$\frac{d^n X}{d u^n} = \frac{d^{n-1} \left[\frac{d X}{d z} \left(\frac{z}{u} \right)^n \right]}{d z^{n-1}} \dots \dots (1),$$

u and z being two functions of x which vanish at the same time, but the ratio of which remains a finite quantity. The demonstration depends on the two following propositions.

1. If, after the differentiations have been performed, considering u as an implicit function of z , we make $z = 0$, we have

$$\frac{d^n u^r \left(\frac{z}{u} \right)^n}{d z^n} = n(n-1)(n-2) \dots (n-r+1) \frac{d^{n-1} \left(\frac{z}{u} \right)^{n-1}}{d z^{n-1}} \dots \dots (2),$$

for supposing $\frac{z}{u} = p$, if we replace u by its value in z , and if we develop p^{n-r} in a series of terms arranged according to the ascending powers of z , we shall find

$$u^r \left(\frac{z}{u} \right)^n = z^r \left(\frac{z}{u} \right)^{n-r} = z^r (A + A' z + A'' z^2 + \dots + A^{(m)} z^m + \&c.);$$

and taking the n^{th} differential coefficient of the general term, we shall obtain

$$(r+m)(r+m-1) \dots (r+m-n+1) A^{(m)} z^{r+m-n},$$

an expression which always vanishes when $z = 0$, except when $r+m-n = 0$, in which case we have

$$\frac{d^n u^r \left(\frac{z}{u} \right)^n}{d z^n} = n(n-1)(n-2) \dots 1 A^{(n-r)};$$

but $A^{(n-r)} = \frac{d^{n-r} p^{n-r}}{1.2.3 \dots n-r}$; therefore $\frac{d^n u^r \left(\frac{z}{u} \right)^n}{d z^n} = n(n-1)(n-2) \dots (n-r+1) \frac{d^{n-r} \left(\frac{z}{u} \right)^{n-r}}{d z^{n-r}}.$

Under the same condition

$$\frac{d^{n-1} u^r d p^n}{d z^n} = \frac{d^n u^r p^n}{d z^n} \dots \dots (3),$$

for

$$\frac{u^r d p^n}{d z} = n u^r p^{n-1} \frac{d p}{d z} = n u^r \left(\frac{z}{u} \right)^{n-1} \frac{d p}{d z} = n z^r \left(\frac{z}{u} \right)^{n-r-1} \frac{d p}{d z} = n z^r p^{n-r-1} \frac{d p}{d z} = \frac{n}{n-r} z^r \frac{d p^{n-r}}{d z},$$

putting for p^{n-r} its development, and performing the differentiation which is indicated, we find

$$\frac{u^r d p^n}{d z} = \frac{n}{n-r} z^r (A' + 2 A'' z + 3 A''' z^2 + \dots + m A^{(m)} z^{m-1} + \&c.);$$

differentiating $n-1$ times this equation, we shall have, according to the value of the general term $d^{n-1} \frac{m n}{n-r}$

$A^{(n-r-1)} z^{r+m-n-1}$, a result which will be equal to nothing as long as we have $r+m-1 > n-1$, and also when we have $r+m-1 < n-1$; thus we have simply

$$\frac{d^{n-1} u^r d p^n}{d z^n} = n(n-1)(n-2) \dots 1 A^{(n-r)} = \frac{d^n u^r p^n}{d z^n}.$$

This supposes that we have $r < n$; for when $r = n$, we have

$$\frac{u^r d \cdot p^n}{dz} = n u^n p^{n-1} \frac{dp}{dz} = n u z^{n-1} \frac{dp}{dz};$$

and when we shall have differentiated $n-1$ times this product, there will remain still in every term at least one of the factors z or u : therefore it will vanish when $z=0$. The same thing will happen if we have $r < n$, on account of the factor u , which will remain in every term.

2. This understood, let us consider the function $X p^n$, let us put in it the developement of X , indicated above, and let us take the differential coefficient of the n^{th} order with respect to z ; we shall obtain

$$\frac{d^n X p^n}{dz^n} = T \frac{d^n \cdot p^n}{dz^n} + \frac{T'}{1} \frac{d^n \cdot u p^n}{dz^n} + \frac{T''}{1 \cdot 2} \frac{d^n \cdot u^2 p^n}{dz^n} + \dots + \frac{T^{(r)}}{1 \cdot 2 \cdot 3 \dots r} \frac{d^n \cdot u^r p^n}{dz^n} + \&c.$$

and substituting for

$$\frac{d^n \cdot u p^n}{dz^n}, \quad \frac{d^n \cdot u^2 p^n}{dz^n}, \dots, \frac{d^n \cdot u^r p^n}{dz^n},$$

their values derived from equation (2), we shall have

$$\frac{d^n \cdot X p^n}{dz^n} = T \frac{d^n \cdot p^n}{dz^n} + \frac{n}{1} T' \frac{d^{n-1} \cdot p^{n-1}}{dz^{n-1}} + \frac{n(n-1)}{1 \cdot 2} \frac{d^{n-2} \cdot p^{n-2}}{dz^{n-2}} + \dots + n T^{(n-1)} \frac{dp}{dz} + T^{(n)},$$

an expression of which the numerical coefficients are those of the binomial formula, and which terminates in the same way because the exponent n is an integer.

If we operate in the same manner on the equation

$$\frac{d^{n-1} \cdot X d \cdot p^n}{dz^{n-1}} = T \frac{d^n \cdot p^n}{dz^n} + \frac{T'}{1} \frac{d^{n-1} \cdot u d \cdot p^n}{dz^n} + \frac{T''}{1 \cdot 2} \frac{d^{n-1} \cdot u^2 d \cdot p^n}{dz^n} + \&c$$

observing that by equations

$$\frac{d^{n-1} \cdot u^r d \cdot p^n}{dz^{n-1}} = \frac{d^n \cdot u^r p^n}{dz^n} = n(n-1) \dots (n-r+1) \frac{d^{n-r} \cdot p^{n-r}}{dz^{n-r}}$$

We shall find

$$\frac{d^{n-1} \cdot X d \cdot p^n}{dz^{n-1}} = T \frac{d^n \cdot p^n}{dz^n} + \frac{n}{1} T' \frac{d^{n-1} \cdot p^{n-1}}{dz^{n-1}} + \frac{n(n-1)}{1 \cdot 2} T'' \frac{d^{n-2} \cdot p^{n-2}}{dz^{n-2}} + \dots + \frac{n}{1} T^{(n-1)} \frac{dp}{dz},$$

an expression which is terminated one term before the preceding, because

$$\frac{d^{n-1} \cdot u^n d \cdot p^n}{dz^{n-1}} = 0.$$

Now, if we take the difference of these two expressions, we shall have

$$\frac{d^n \cdot X p^n}{dz^n} - \frac{d^{n-1} X d p^n}{dz^{n-1}} = T^n = \frac{d^n X}{d u^n};$$

and if we reduce to one the two terms of the left side of the equation, we shall find

$$\frac{d^{n-1} \left(\frac{d \cdot X p^n}{dz} - X \frac{d \cdot p^n}{dz} \right)}{dz^{n-1}} = \frac{d^{n-1} \left(\frac{d X}{dz} \cdot p^n \right)}{dz^{n-1}} = \frac{d^n X}{d u^n}$$

which is the theorem of Burmann.

(246.) By means of this theorem we first obtain that of Lagrange, by making

$$z = x - a, \text{ and } u = \frac{x-a}{\phi(x)}, \text{ hence } p = \phi(x), dz = dx, \text{ and } \frac{d^n X}{d u^n} = \frac{d^{n-1} \left(\phi^n \frac{d X}{dx} \right)}{d x^{n-1}} = \frac{d^{n-1} (\phi^n \psi')}{d x^{n-1}},$$

changing X into $\psi(x)$, and then making $z=0$ and $x=a$ after the differentiations; we shall observe afterwards that the equation $u = \frac{x-a}{\phi(x)}$ gives $x = a + u \phi(x)$; and if we make $u=1$, write y instead of x , we shall find the formula of Lagrange.

Let us assume $X = \psi(x)$, $u = \phi(x) - \phi(a)$, $z = x - a$, then we shall obtain

$$\psi(x) = \psi(a) + \frac{T'}{1} [\phi(x) - \phi(a)] + \frac{T''}{1 \cdot 2} [\phi(x) - \phi(a)]^2 + \&c. \dots +$$

an expression in which

$$T^{(n)} = \frac{d^{n-1}}{d x^{n-1}} \left\{ \left(\frac{\phi(x) - \phi(a)}{x-a} \right)^n \psi'(x) \right\}.$$

(247.) If we suppose $\phi(a) = 0$, the preceding formulæ are simplified, and become

$$\psi(x) = \psi(a) + \frac{T'}{1} \phi(x) + \frac{T''}{1 \cdot 2} \phi(x)^2 + \frac{T'''}{1 \cdot 2 \cdot 3} \phi(x)^3 + \&c. \text{ where } T^{(n)} = \frac{1}{d x^{n-1}} d^{n-1} \left[\left(\frac{\phi(x)}{x-a} \right)^n \psi'(x) \right].$$

Which remarkable formula is the developement of $\psi(x)$ in a series of terms arranged according to the powers

Part III.
Integral
Calculus.

 of $\phi(x)$; and since a designates a value of x which satisfies the equation $\phi(x) = 0$, there will be as many of these developements as this equation has roots. Let us take for an example

Part III.

$$\psi(x) = b^x, \quad \phi(x) = x c^x.$$

We have then

$$a = 0, \quad \psi'(x) = b^x l b, \quad T^{(n)} = \frac{1}{d x^{n-1}} d^{n-1} [c^{-nx} b^x l b] = l b (l b - n l c)^{n-1} c^{-n} b^x;$$

 and if we make $x = 0$, after the differentiations, we find

$$b^x = 1 + l b \frac{x c^x}{1} + l b (l b - 2 l c) \frac{x^2 c^{2x}}{1.2} + l b (l b - 3 l c)^2 \frac{x^3 c^{3x}}{1.2.3} + \&c.$$

 (See for more details on the developements of functions in series *Mémoire de M. Servois*, in the Vth Volume of the *Annales de Mathématiques*, and the last Chapter of the *Disquisitiones Analyticae* of Pfaff.)

 (248.) The first problem which Arbogast proposes to resolve in his *Traité des Dérivations*, is to develop according to the powers of x , an expression such as

$$\phi(a + \beta x + \gamma x^2 + \delta x^3 + \&c \dots),$$

 ϕ designating any function whatever. It is obvious that this developement is, with respect to Taylor's Theorem, exactly the same thing as the developement of the polynom

$$(a + \beta x + \gamma x^2 + \delta x^3 + \&c.)^m$$

with respect to the binomial theorem.

To apply Taylor's Theorem to the above proposed function, it is first necessary to put it under the form of a binomial quantity. Let us assume

$$a + \beta x + \gamma x^2 + \delta x^3 + \&c. = a + t x,$$

 so that $t = \beta + \gamma x + \delta x^2 + \&c. \dots$; considering then a as the variable, and $t x$ as its increment, we shall have by Taylor's Theorem, representing for the sake of brevity $\phi(a)$ by ϕ ,

$$\phi(a + t x) = \phi + \frac{d \phi}{d a} t x + \frac{d^2 \phi}{d a^2} \frac{t^2 x^2}{1.2} + \frac{d^3 \phi}{d a^3} \frac{t^3 x^3}{1.2.3} + \&c.$$

 and thus the developement depends on those of the powers of the algebraical function t .

 If it were required to find the coefficient of x^n , it would be necessary and sufficient to take the first term of the n^{th} power of t , the second of the $(n-1)^{\text{th}}$, and so on. Let us represent the developement of t^r by

$$T_0^r + T_1^r x + T_2^r x^2 + \dots + T_r^r x^r,$$

 so that the superior index of the letter T shows the degree of the power to which is raised the polynom t , and the inferior that of the letter x , according to this notation, the general term of the developement of $\phi(a + t x)$ will be

$$\left\{ \frac{d^n \phi}{1.2 \dots n d a^n} T_0^n + \frac{d^{n-1} \phi}{1.2 \dots (n-1) d a^{n-1}} T_1^{n-1} + \frac{d^{n-2} \phi}{1.2 \dots (n-2) d a^{n-2}} T_2^{n-2} + \dots + \frac{d \phi}{d a} T_{n-1}^1 \right\} x^n.$$

 Therefore if we had the general expression of the coefficient T_r , we should know the general term of the developement of $\phi(a + \beta x + \gamma x^2 + \dots)$; but this research cannot find place here, on account of its length, and, besides, it belongs rather to another branch of analysis, called *Combinatorial analysis*.

On the Values assumed, in certain Cases, by Differential Coefficients, and on the Value of Functions, which under certain Circumstances become $\frac{0}{0}$.

(249.) The formulæ of developement we have obtained in the preceding pages, depend all on the particular values which the differential coefficients of the function to be developed take, when nothing or certain constant quantities are substituted for the variables. They can, therefore, only be applied in those cases where the values of the differential coefficients are finite, a circumstance which does not always take place. The function

 $y = b + (x - a)^{\frac{1}{n}}$, n being supposed to be greater than one, offers a very simple example of it; for if we differentiate it, we find

$$\frac{d y}{d x} = \frac{1}{n} (x - a)^{\frac{1}{n} - 1} = \frac{1}{n (x - a)^{\frac{n-1}{n}}};$$

 and if we make $x = a$, a supposition which gives $y = b$, the value of $\frac{d y}{d x}$ becomes infinite. It will be the same

 thing with respect to the differential coefficients of superior order, for each differentiation increases the exponent of $(x - a)$ in the denominator. In the numbers (234.) and (235.) we have assumed that the functions which we have considered could be developed according to the integral powers of the variables; but this supposition may be wrong, and we shall know that it is so, when in calculating the coefficients of the developement, by

means of the values of differential coefficients of the function, corresponding to a particular value of x , we shall find that any one of them becomes infinite.

To make this clearer, let $y = f(x)$, and let us suppose that the developement of $f(a+x)$ according to the powers of x contains fractional exponents of x . Let

$$f(x+a) = f(a) + Px + Qx^2 + \dots + Tx^n + Vx^{\frac{m+1}{m}} + \&c.$$

If in the series no fractional exponent occurs before the term $Vx^{\frac{m+1}{m}}$, all the coefficients $P, Q, \dots, T$, may be calculated by means of the method explained in the numbers (234.) and (235.), and thus we shall have

$$P = \frac{dy}{dx}, \quad Q = \frac{d^2y}{dx^2}, \quad \dots \quad T = \frac{d^ny}{dx^n};$$

but if we try to employ the same method to find the value of the coefficient V , by taking the differential coefficient of the $(n+1)^{th}$ order, we obtain

$$\frac{d^{n+1}f(x+a)}{dx^{n+1}} = \left(\frac{mn+1}{m}\right) \left(\frac{mn+1}{m} - 1\right) \left(\frac{mn+1}{m} - 2\right) \dots 1 V x^{\frac{1-m}{m}} + \&c.$$

Now since the exponent $\frac{1-m}{m}$ of x is negative, the supposition $x=0$ will make the right side of the equation

infinite; therefore, this same supposition must also render equal to infinity the differential coefficient $\frac{d^{n+1}f(x+a)}{dx^{n+1}}$ and the value of V cannot be obtained by means of it. It will be the same with respect to the differential coefficients of superior order.

(250.) There is here, however, an apparent difficulty. We have observed before (231.) that the developement of $f(a+x)$ could be derived from the developement of $f(x+h)$, given by Taylor's Theorem, by substituting in that developement a for x , and x for h . It has been proved, besides, that the series of Taylor, as long as both x and h remain variable, can only contain integral powers of h . It might then be imagined that the developement of $f(a+x)$ derived from it, by giving a particular value to one of the variables, ought also to contain only integral powers of x , and be found in all cases as in number (235.)

It must be observed that the developement of $f(x+h)$ ought to have neither more nor less values than the function itself; and it is for that reason, as it has been explained before, that as long as x and h remain variables, the developement of $f(x+h)$ cannot contain a term with a fractional exponent of h . But the reasoning which has been used can no longer be applied, when one of the variables receives a particular value, because the number of values of the coefficients of the series may become less than the number of values of the function, and this deficiency must be made up by the terms containing fractional exponents.

Let us take, as an example, the function $y = b \pm \sqrt{x-a}$; by taking alternately the radical with the sign $+$ and with the sign $-$, we shall have

$$\frac{dy}{dx} = \pm \frac{1}{2} (x-a)^{-\frac{1}{2}}, \quad \frac{d^2y}{dx^2} = \mp (x-a)^{-\frac{3}{2}}, \quad \&c.$$

and if $y' = b \pm \sqrt{x+h-a}$, we shall find

$$y' = b + \sqrt{x-a} + \frac{1}{2} (x-a)^{-\frac{1}{2}} h - (x-a)^{-\frac{3}{2}} \cdot \frac{h^2}{1 \cdot 2} + \&c. \quad \text{or}$$

$$y' = b - \sqrt{x-a} - \frac{1}{2} (x-a)^{-\frac{1}{2}} h + (x-a)^{-\frac{3}{2}} \frac{h^2}{1 \cdot 2} - \&c.$$

These developements contain only integral powers of h , and we see a reason for it in this circumstance that no particular value being substituted for x , the coefficients of the series, which are the differential coefficients of the function, have as many values as y . But if we suppose $x=a$, the radical quantity $\sqrt{x-a}$ in the function y disappears, and the two values of y become equal to b . Therefore if the developement of y' were still of the form $y' + Ph + Qh^2 + Rh^3 + \&c.$ it would have only one value, whilst y' would have two, since it becomes then equal to $b \pm \sqrt{h}$. Hence the form of the developement must change, and the series must contain fractional powers of h . Analysis shows this change of form in giving infinite values for the differential coefficient $\pm \frac{1}{2} (x-a)^{-\frac{1}{2}}$ when $x=a$; and the truth of this reasoning is verified since, in that case, the developements of

the two values of y' are simply $b + h^{\frac{1}{2}}$ and $b - h^{\frac{1}{2}}$.

(251.) The methods explained (234.) and (235.) cannot therefore be used to develop $f(x)$ or $f(a+x)$ according to the powers of x , when these functions are such that the series which represent them ought to contain fractional powers of x . Neither can they be used if the series ought to contain negative powers of x , since we have assumed that the functions $f(x)$ and $f(a+x)$ did not become infinite for $x=0$. To develop the functions in these cases some other process must be used. The coefficients of the developement may be determined, for instance, in the following manner.

Let us assume generally, $f(a+x) = Ax^{-a} + Bx^{\beta} + Cx^{\gamma} + \&c.$ the exponents $a, \beta, \gamma, \&c.$ being supposed to be arranged in ascending order.

To find the value of a , let such a power of x be found as being multiplied by the given function $f(a+x)$ will give a product which becomes neither $=0$, nor infinite when $x=0$, the exponent of this power will be a .

Integral
Calculus.

For if not, let it be κ , then $f(a+x)x^\kappa = Ax^{\kappa-a} + Bx^{\kappa+\beta} + Cx^{\kappa+\gamma} + \&c.$ The exponents are arranged in an ascending order, therefore they are all positive if $\kappa - a$ is positive, and all the terms vanish when $h = 0$, which is contrary to hypothesis. If κ were $< a$, then the first exponent at least is negative, and the series would become infinite for $x = 0$, which is also contrary to hypothesis. Therefore $\kappa = a$. The exponent a being thus found, the coefficient A is what $f(a+x)x^a$ becomes when $x = 0$.

Having thus determined A and a , the first term of the developement becomes known, and being brought in the left side of the equation gives $f(a+x) - Ax^{-a} = Bh^\beta + Ch^\gamma + Dh^\delta + \&c.$ The left side of this equation being known, if b be negative, it may be found by the same process as that used to determine a . It may be known whether it be negative by determining if $x = 0$ render $f(a+x) - Ax^{-a}$ infinite. If $h = 0$ render this $= 0$, then β is > 0 , and we shall presently explain the method of determining it. If $h = 0$ do not render $f(a+x) - Ax^{-a}$ either $= 0$ or infinite, then $b = 0$, and the value of $f(a+x) - Ax^{-a}$ when $x = 0$ is the value of B . The other exponents, when negative, and coefficients may be determined in a similar way.

There is another method of finding the negative exponents when they are integers founded on the application of the Integral Calculus. Let $f(a+x) = Ax^{-a} + Bx^\beta + Cx^\gamma + \&c.$ Multiply both sides by dx , and integrate,

we find $\int f(a+x) dx = \frac{1}{1-a} Ax^{1-a} + \frac{1}{1+\beta} Bx^{1+\beta} + \frac{1}{1+\gamma} Cx^{1+\gamma} + \&c.$ Let $\int f(a+x) dx = f_1(a+x)$.

Multiplying again by dx , and integrating, we find $\int f_1(a+x) dx = \frac{1}{1-a} \cdot \frac{1}{2-a} Ax^{2-a} + \frac{1}{1-\beta} \cdot \frac{1}{2-\beta}$

$Bx^{2+\beta} + \&c.$ Let this process be continued until an integral be found, which will neither vanish nor be infinite when $x = 0$. If one be found which vanishes when $x = 0$, immediately next to another which becomes infinite for that supposition, then a is a fraction whose value is between the number of integrations and the integer next below it. If the value of the integral be finite, then a is equal to the number of integrations.

If $x = 0$ does not render infinite $f(a+x)$, the developement cannot contain negative powers of x , and the series will be $f(a+x) = f(a) + Bx^\beta + Cx^\gamma + Dx^\delta + \&c.$ Differentiating we get $\frac{df(a+x)}{dx} = \beta Bx^{\beta-1} + \gamma$

$Cx^{\gamma-1} + \delta Dx^{\delta-1} + \&c.$ Now, if $x = 0$ renders $\frac{df(a+x)}{dx}$ infinite, $-\beta - 1$ is negative, and therefore β is a fraction. To determine its value, let $f(a)$ be brought in the left side of the equation, we shall have $f(a+x) - f(a) = Bx^\beta + Cx^\gamma + Dx^\delta + \&c.$ and then let that power of x be found, by which $f(a+x) - f(a)$ being divided, the quotient will neither vanish nor become infinite when $x = 0$. The exponent of that power will obviously be equal to β .

If $x = 0$ did not render infinite neither $f(a+x)$ nor $\frac{df(a+x)}{dx}$, but $\frac{d^2f(a+x)}{dx^2}$, then we would have $\beta = 1$,

B equal to the value of $\frac{d^2f(a+x)}{dx^2}$ for $x = 0$, and γ would be a fraction > 1 whose value might be determined in a similar manner.

It follows, therefore, in general, that if $x = 0$ renders the n^{th} differential coefficient of $f(a+x)$ infinite, but none of the preceding ones, the methods given (235.) will give the true developement as far as the n^{th} term inclusive; but the exponent of x in the $(n+1)^{\text{th}}$ term is a fraction whose value is between the integers n and $n+1$, and which may be determined by the method explained above.

(252.) When for a particular value given to a variable x , a function of that variable takes the form $\frac{0}{0}$, it has always a determinate value which is either a finite quantity, or equal to nothing or infinity. The Differential Calculus gives, in most cases, very simple means to find the true value of the function. Let $\frac{X}{X'}$ be a fraction the numerator and denominator of which vanish for $x = a$. If we substitute $a+h$ for x , the functions X and X' may always be supposed to be developed in series arranged according to the ascending powers of h . Let these series be represented by $Ah^a + Bh^\beta + \&c.$, and $A'h^{a'} + B'h^{\beta'} + \&c.$, since they must become equal to nothing when $h = 0$, which answers to $x = a$. We shall have therefore $\frac{Ah^a + Bh^\beta + \&c.}{A'h^{a'} + B'h^{\beta'} + \&c.}$

instead of the proposed function. If in this fraction we suppose $h = 0$, we must find the same result as if we made $x = a$ in $\frac{X}{X'}$. Three cases may occur: we may have $a > a'$, $a = a'$, $a < a'$; in the two first the preceding expression may be written in the following manner:

$$\frac{Ah^{a-a'} + Bh^{\beta-a'} + \&c.}{A' + B'h^{\beta'-a'} + \&c.}$$

Under this form it is easy to see that if we have $a > a'$, the supposition $h = 0$ will make the fraction equal to nothing, and that it will be reduced to $\frac{A}{A'}$, when we shall have $a = a'$. On the contrary if we have $a < a'$ the fraction may be written as follows, dividing both numerator and denominator by h^a ,

Integral
Calculus.

$$\frac{A + B h^{a-a} + \&c.}{A' h^{a'-a} + B' h^{a'-a} + \&c.},$$

and will become infinite by the supposition of $h = 0$.

In each of the three cases, the true value of the fraction depends only upon the first term of each series.

(253.) To render the case more general we have supposed that the functions obtained by substituting $a + h$ for x into X and X' , could not be developed according to the integral powers of h , but if this can be done, then the fraction becomes (235.)

$$\frac{X_a + \frac{dX}{da} h + \frac{d^2 X}{da^2} \frac{h^2}{1.2} + \&c.}{X'_a + \frac{dX'}{da} h + \frac{d^2 X'}{da^2} \frac{h^2}{1.2} + \&c.},$$

$X_a, X'_a, \frac{dX}{da}, \frac{dX'}{da}, \&c.$ designating what $X, X', \frac{dX}{dx}, \frac{dX'}{dx}$ become when a is substituted for x . By hypothesis

$X_a = 0$, and $X'_a = 0$. If, at the same time, all the differential coefficients in the numerator up to the m^{th} order, and all those of the denominator up to the n^{th} order, become equal to nothing, the fraction will be reduced to

$$\frac{\frac{d^m X}{dx^m} \cdot \frac{h^m}{1.2 \dots m} + \&c.}{\frac{d^n X'}{da^n} \cdot \frac{h^n}{1.2 \dots n} + \&c.},$$

a quantity which will be equal to nothing if we have $m > n$, infinite if we have $m < n$, and equal to

$$\frac{\frac{d^m X}{dx^m}}{\frac{d^n X'}{da^n}},$$

if $m = n$. Hence, to obtain the true value of a function which becomes $\frac{0}{0}$ when a particular value is substituted for x , it is generally sufficient to find the successive differential coefficients of its numerator and its denominator, till we find for the one, or for the other, a result which does not become equal to nothing for the particular value of x ; the proposed function will become infinite in the first case, equal to nothing in the second; and if it have a finite value, the two differential coefficients of the numerator and denominator which do not vanish will be of the same order, and their quotient will be the value required.

This rule supposes that none of the coefficients which are successively calculated becomes infinite for the particular value of x ; if that were the case, it would indicate that one or both the functions resulting from the substitution of $a + h$ for x in X and X' cannot be developed according to the integral powers of h , and they should consequently be treated as in number (252.).

A few examples will elucidate the preceding rule.

Example 1. Let the proposed function be $\frac{a^3 - x^3}{a^2 - x^2}$, the supposition $x = a$ reduces it to the form $\frac{0}{0}$, it is required to find its true value.

$\frac{d(a^3 - x^3)}{dx} = -3x^2$ and for $x = a$ becomes $-3a^2$; $\frac{d(a^2 - x^2)}{dx} = -2x$, and for $x = a$ becomes $-2a$; therefore the true value is $\frac{3a^2}{2a} = \frac{3a}{2}$.

In the same manner the true value of $\frac{x^n - 1}{x - 1}$ for $x = 1$ is found to be equal to n .

Example 2.

$$\frac{ax^3 - 2acx + ac^3}{bx^3 - 2bcx + bc^3}, \text{ for } x = c.$$

$\frac{d(ax^3 - 2acx + ac^3)}{dx} = 2ax - 2ac$, which quantity becomes nothing for $x = c$; $\frac{d(bx^3 - 2bcx + bc^3)}{dx} = 2bx - 2bc$, and this quantity is also reduced to nothing when $x = c$. It is therefore necessary to differentiate again; we find then $\frac{d(2ax - 2ac)}{dx} = 2a$, and $\frac{d(2bx - 2bc)}{dx} = 2b$, therefore the true value of the fraction is $\frac{a}{b}$.

Example 3.

$$\frac{a^x - b^x}{x} \text{ for } x = 0.$$

$\frac{d(a^x - b^x)}{dx} = a^x \log a - b^x \log b$, $\frac{dx}{dx} = 1$. Therefore the true value is $\log a - \log b = \log\left(\frac{a}{b}\right)$.

Part III.
Integral
Calculus.

Part III.

In the same manner it will be found that the true value of $\frac{1 - \sin x + \cos x}{\sin x + \cos x - 1}$ for $x = \frac{\pi}{2}$ is equal to -1 .

Example 4. Sometimes it will be found that it is simpler, instead of calculating the differential coefficients, to develop the numerator and denominator after having substituted $a + h$ for x . The fraction

$$\frac{x^3 - 4ax^2 + 7a^2x - 2a^3 - 2a^2\sqrt{2ax - a^2}}{x^2 - 2ax - a^2 + 2a\sqrt{2ax - a^2}}$$

is an example of this case. It is only after differentiating four times the numerator and denominator that the true value, corresponding to $x = a$, is found. If instead of that process we substitute $a + h$ for x and reduce, we find first

$$\frac{2a^3 + 2a^2h - ah^2 + h^3 - 2a^2\sqrt{a^2 + 2ah}}{-2a^2 + h^2 + 2a\sqrt{a^2 - h^2}}.$$

Reducing in series the two radical quantities we shall find

$$\sqrt{a^2 + 2ah} = a + h - \frac{h^2}{2a} + \frac{h^3}{2a^2} - \frac{5h^4}{8a^3} + \&c. \quad \sqrt{a^2 - h^2} = a - \frac{h^2}{2a} - \frac{h^4}{8a^3} + \&c.$$

The substitution of these two series in the preceding fraction, and the supposition of $h = 0$, will give $-5a$ for the true value required.

Example 5. Let the proposed function be $\frac{(x^2 - a^2)^{\frac{3}{2}}}{(x - a)^{\frac{3}{2}}}$, it is required to find the true value for $x = a$. Here the

differential coefficients become infinite, and therefore it is necessary to use the general method. By substituting $a + h$ for x and developing, we find thus that the function becomes

$$\frac{(2ah + h^2)^{\frac{3}{2}}}{h^{\frac{3}{2}}} = (2a + h)^{\frac{3}{2}}.$$

Making then $h = 0$, we obtain for the true value $(2a)^{\frac{3}{2}}$.

(254.) A function may, for a particular value of x , take various indeterminate forms, differing in appearance from $\frac{0}{0}$, but which in reality come to the same thing.

1. The numerator and denominator of the fraction $\frac{X}{X'}$ may become both infinite at the same time. This case

may immediately be reduced to the one we have already examined by putting the fraction under the form $\frac{\left(\frac{1}{X'}\right)}{\left(\frac{1}{X}\right)}$.

2. In the product PQ of two functions of x , one of the factors may become equal to nothing for a particular value of x , and the other infinite; such is the case, for instance, for the expression $(1 - x) \tan \frac{\pi x}{2}$ when $x = 1$.

To reduce this case to the form $\frac{X}{X'}$, it is sufficient to make $Q = \frac{1}{R}$, then $PQ = \frac{P}{R}$, and the rules given may be applied.

3. It may be required to find the value of the difference $P - Q$ of two functions, when they both become infinite for a particular value of the variable. If the two functions are both rational, algebraical, and integral, the only value of x for which they can become infinite is x equal to infinity, and consequently the only case in which the expression $P - Q$ may have a finite value is when $P = Q + b$, b being a constant quantity. When P and Q are fractions the denominators of which vanish, it is easy to change the proposed function into another

which becomes $\frac{0}{0}$; it is sufficient for that to bring P and Q to the same denominator. In many cases the true

value of the function may also be obtained by substituting for x the particular value increased by h , and developing according to the powers of h . Let us take as an example the function $\frac{x}{x-1} - \frac{1}{l x}$, which when $x = 1$

becomes the difference of two infinite quantities. If we substitute $1 + h$ for x , it becomes $\frac{1+h}{h} - \frac{1}{l(1+h)}$.

But $l(1+h) = h - \frac{h^2}{2} + \frac{h^3}{3} - \&c$. Therefore

$$\frac{1+h}{h} - \frac{1}{l(1+h)} = \frac{(1+h)l(1+h) - h}{hl(1+h)} = \frac{\frac{h^2}{2} - \frac{h^3}{2 \cdot 3} + \&c.}{h^2 - \frac{h^3}{1 \cdot 2} + \&c.}$$

Integral Calculus Dividing both numerator and denominator by h^2 , and making afterwards $h = 0$, we find $\frac{1}{2}$ for the true value of Part III.
 $\frac{x}{x-1} - \frac{1}{lx}$.

In an analogous manner we should find for the true value of $\frac{1}{2x^2} - \frac{\pi}{2x \tan \pi x}$, corresponding to $x = 0, \frac{\pi}{6}$.

(255) We shall take for the last example the function $\frac{lx}{x}$, the numerator and denominator of which become infinite when x is supposed to be infinite. The rule given in the preceding number does not apply, for by preparing the function in the manner indicated, and then differentiating both the numerator and denominator, we find

$$\frac{\frac{1}{x}}{\frac{1}{lx}} \text{ and } \frac{d \cdot \frac{1}{x}}{d \cdot \frac{1}{lx}} = \frac{\frac{1}{x^2}}{\frac{1}{x(lx)^2}} = \frac{(lx)^2}{x},$$

a result from which no conclusion can be drawn. The simplest means to find the true value of the function or more generally of $\frac{lx}{x^n}$, is to develop x^n , considering it as an exponential, according to the powers of n ; we have then

$$\frac{lx}{x^n} = \frac{lx}{1 + lx \cdot \frac{n}{1} + (lx)^2 \cdot \frac{n^2}{1 \cdot 2} + (lx)^3 \cdot \frac{n^3}{1 \cdot 2 \cdot 3} + \&c.} = \frac{1}{\frac{1}{lx} + \frac{n}{1} + (lx)^2 \cdot \frac{n^2}{1 \cdot 2} + (lx)^3 \cdot \frac{n^3}{1 \cdot 2 \cdot 3} + \&c.}$$

The last expression having a constant quantity for its numerator, whilst its denominator increases with the value of x , and becomes infinite at the same time as this quantity, it follows that the value of $\frac{lx}{x^n}$ has for limit nothing.

Knowing the value of $\frac{lx}{x^n}$, when x is infinite, it is easy to find the values of other analogous functions.

1. The function $\frac{x^n}{lx}$ being equal to $\left(\frac{lx}{x^n}\right)^{-1}$ becomes clearly infinite when the last becomes nothing.
2. The function $x^n lx$, which becomes nothing multiplied by an infinite quantity when $x = 0$, has for true value nothing, for if we suppose $x = \frac{1}{y}$ it is transformed into $\frac{-ly}{y^n}$. The function $x^n (lx)^r$ has also the same value for $x = 0$, for by extracting the root of the degree r , it becomes $x^{\frac{n}{r}} lx$, and the value of the root for $x = 0$ must be the same as that of the function.

On the Maxima and Minima of Functions of One Variable.

(256.) Let u be a function of the variable x , and u', u'', u''' represent the three values of u corresponding respectively with $x = a - h$, $x = a$, $x = a + h$; then if u be a continuous function for values differing but little from a (see number (71.)), and if a be such a quantity that for any very small value of h , u' and u''' be both less than u'' , then this last quantity is said to be a *maximum* of the function u . It is said to be a *minimum* when under the same circumstances u' and u''' are both greater than u'' . In the same case, a is said to be a value of the variable corresponding to a maximum or to a minimum of the function. Hence it is clear, for instance, that the value $x = a$ corresponds to a maximum or a minimum of the function $b \mp (x - a)^2$, according as the second term $(x - a)^2$ is taken with the sign $-$ or $+$. It is also obvious, that the maximum or minimum of a function, from the definition given above, is not necessarily the same thing as the greatest or least value of the function. Thus, for instance, the value b^2 of the function $b^2(x - 1) + (x - 2)^2(x - 1)^2$, corresponding to $x = 2$, is a minimum, and nevertheless the value of the same function corresponding to $x = 1$ is equal to nothing. Another consequence of the definition which has been given of the maximum or minimum of a function, is that the same function may have several maxima and minima; such is the case for the function $a + b(x - 1)^2 + c(x - 2)^2(x - 1)^4$, the values of which corresponding to $x = 1$ and $x = 2$ are both minima.

(257.) Two questions present themselves relative to the maxima and minima of functions of one variable; they are not, however, essentially distinct, and the solution given for the first shows immediately how to resolve the second. The first is to determine if a given value of the variable does or does not correspond to a maximum or a minimum of the function, and the second to find all the values of the variable answering to maxima and minima.

(258.) Let $u = f(x)$ be the proposed function, and a the given value of x . It is required to determine whether it corresponds to a maximum or a minimum. Let $a + h$ be substituted for x , in the function, and let the result be developed according to the powers of h . The development may contain fractional powers of h ; let it be represented generally by

$$f(a + h) = f(a) + P h^\alpha + Q h^\beta + R h^\gamma + \&c.$$

where α, β, γ may be integral or fractional numbers, but where they are supposed arranged in an ascending order.

Integral
Calculus.

This understood, the developement of $f(a-h)$ may be deduced from that of $f(a+h)$ by writing $-h$ instead of h , and we shall have accordingly

$$f(a-h) = f(a) + P(-h)^a + Q(-h)^b + R(-h)^c + \&c.$$

Hence the differences, $f(a) - f(a+h)$, and $f(a) - f(a-h)$, will be respectively

$$-Ph^a - Qh^b - Rh^c - \&c., \quad -P(-h)^a - Q(-h)^b - R(-h)^c - \&c.$$

Now, if a correspond to a maximum, that is if $f(a)$ be a maximum of $f(x)$, both $f(a+h)$ and $f(a-h)$ must be less than $f(a)$ for any value of h sufficiently small, and consequently the two above differences should be positive. It is obvious, in a similar manner, that they should be both negative if a correspond to a minimum. This must be true however small be the value taken for h . By taking h sufficiently small, the sign of each series will be the same as that of the first term; hence a will correspond to a maximum if both Ph^a and $P(-h)^a$ are negative, and to a minimum if they are positive.

But the two quantities Ph^a and $P(-h)^a$ cannot be of the same sign unless a should be equal to an even integral number, or to a fraction which, reduced to its lowest terms, should have an even number for numerator. In both cases we shall have

$$f(a) - f(a+h) = -Ph^a - \&c., \quad f(a) - f(a-h) = -Ph^a - \&c.$$

and $f(a)$ will be a maximum if P be negative, and a minimum if it be positive.

To make use of this observation, we shall distinguish two cases, namely, when a is an integer, and when it is a fraction.

In the first case, we have (235.) $P = \frac{1}{1 \cdot 2 \dots a} \frac{d^a u}{d a^a}$, and since the exponent a must be an even number when $f(a)$ is a maximum or a minimum, it is first necessary that the value $x = a$ should reduce to nothing the first differential coefficient $\frac{d u}{d x}$, for otherwise the developement of $f(a+h)$ would begin by the term $\frac{d u}{d a} h$, that is to say by a term containing an odd power of h . It is necessary besides that this value $x = a$ should not reduce to nothing the differential coefficient $\frac{d^2 u}{d x^2}$, or if that happen, then it should, at the same time, reduce to nothing, the third differential coefficient $\frac{d^3 u}{d x^3}$, but not the fourth $\frac{d^4 u}{d x^4}$, and, generally, it is necessary that the first differential coefficient which the supposition $x = a$ does not make equal to nothing, should be of an even order. Then if this coefficient becomes a positive quantity when x is made equal to a , this value corresponds to a minimum, and if negative to a maximum of the function.

Let us examine now the second case, that is when a is a fractional number. This quantity may be either greater or less than one. If greater, it is necessary, as before, that the value of $\frac{d u}{d x}$ corresponding to $x = a$ should be equal to nothing, since otherwise the developement of $f(a+h)$ would begin by the term $\frac{d u}{d a} h$, and more generally it is necessary that the value $x = a$ should reduce to nothing all the differential coefficients, the orders of which are less than a .

And, finally, if we have $a < 1$, then $\frac{d u}{d x}$ must become infinite for the value $x = a$.

From what precedes it is easy to infer, that the values of x , corresponding to maxima and minima, can only be found among the roots of the equations $\frac{d u}{d x} = 0$, or $\frac{1}{\frac{d u}{d x}} = 0$. To find all the maxima and minima of the function each of these roots must be examined, to determine which of them, if any, satisfy the conditions stated above.

(259.) We shall now, to elucidate these rules, apply them to some examples.

Example 1. Let the proposed function $u = b + c(x-a)^n$, n being an integer. By making the first differential coefficient equal to nothing, we have the equation $\frac{d u}{d x} = nc(x-a)^{n-1} = 0$, which is only satisfied by the value $x = a$. This value reduces to nothing all the differential coefficients of u up to that of the n^{th} order exclusively. Hence it follows that if n be an odd number, the proposed function will have neither maximum nor minimum, but if n be an even number, the value $x = a$ will make u a maximum when c is negative, and a minimum when it is positive.

Example 2. Let $u = b + c(x-a)^{\frac{2}{3}}$, then $\frac{d u}{d x} = \frac{2}{3}c(x-a)^{-\frac{1}{3}}$. This quantity becoming infinite for $x = a$, there may be a maximum or a minimum of the function corresponding to $x = a$. We must, in this case, develope according to the powers of h the result of the substitution of $a+h$ for x in the function. By this substitution,

Integral
Calculus.

the function becomes $b + ch^{\frac{2}{3}}$, and, therefore, requires no further development. Moreover, the exponent of h being a fraction whose numerator is an even number, we immediately see that the value $x = a$ will correspond to a maximum if c be negative, and to a minimum if c be positive.

Example 3. To divide a number a into two parts such, that the product of the m^{th} power of the first, and the n^{th} power of the second, shall be a maximum or a minimum.

If x be one of the parts, the other is $a - x$, and, consequently, the function $u = x^m (a - x)^n$. We have

$$\frac{du}{dx} = (a - x)^{n-1} \cdot x^{m-1} \cdot \{ma - (m+n)x\} \text{ and } \frac{d^2u}{dx^2} = (a-x)^{n-2} \cdot x^{m-2} \{(ma - (m+n)x)^2 - m(a-x)^2 - nx^2\}.$$

The values of x which render $\frac{du}{dx} = 0$, are determined by the equations

$$a - x = 0, \quad x = 0, \quad ma - (m+n)x = 0,$$

which give $x = a$, $x = 0$, $x = \frac{ma}{m+n}$. The value $x = a$ renders the differential coefficient of the second order

equal nothing; and it is evident that since every differential coefficient of an order inferior to the n^{th} will have $(x - a)$ or some power of it as a factor, the same value of x will render all these $= 0$. The n^{th} differential coefficient will not have the factor $x - a$, and, therefore, by changing in it, x into a , the result will not be found $= 0$. If n be odd therefore, this value of x does not correspond to either a maximum or minimum, and if n be even, it will be found that the value $x = a$ renders the differential coefficient positive, and that, therefore, the function is a minimum.

Similar observations apply to the value $x = 0$. The value $x = \frac{ma}{m+n}$ being substituted for x in $\frac{d^2u}{dx^2}$, renders it negative, and therefore renders the function a maximum.

Example 4. Let $u = \frac{lx}{x^n}$. We get $\frac{du}{dx} = \frac{x^{n-1} - nx^{n-1}lx}{x^{2n}} = \frac{1 - nlx}{x^n + 1}$, and the value of x which makes $\frac{du}{dx} = 0$ is given by the equation $1 - nlx = 0$, or $lx = \frac{1}{n}$, or $x = \frac{1}{e^n}$. To find the value of $\frac{d^2u}{dx^2}$ corresponding

to that value, we may observe, that it is not necessary to differentiate the denominator of the value of $\frac{du}{dx}$, for it would be multiplied by the numerator which the value $x = \frac{1}{e^n}$ annihilates. Thus we shall have simply $\frac{-n}{x^{n+2}}$, a negative quantity, and which will remain so by the substitution of the value of x ; therefore this value corresponds to a maximum of the function.

Example 5. Let $u = \sqrt{x}$, or $u = x^{\frac{1}{2}}$. By taking the logarithms of both sides, we first find $lu = \frac{1}{x} lx$, and by differentiation $\frac{du}{u} = \frac{dx - dx lx}{x^2}$; hence $\frac{du}{dx} = \frac{u}{x^2} (1 - lx)$. This value of $\frac{du}{dx}$ may become equal to nothing in two different ways, either by making $1 - lx = 0$, that is $x = e$, or by making $\frac{u}{x^2} = 0$. In the first case the value of $\frac{d^2u}{dx^2}$ is reduced to $\frac{-u}{x^3}$, and indicates a maximum. In the second case, we may observe that $\frac{u}{x^2} = \frac{1}{x^{\frac{3}{2}}}$, and, under this form, it is obvious that the value of $\frac{u}{x^2}$ diminishes as x increases, and becomes equal to nothing, only when x is infinite.

Example 6. For the last example we shall propose to find in the line joining the centres of two spheres, the point from which the greatest portion of spherical surface is visible.

Let r and r' be the radii of the spheres A and A' , d the distance of their centres, and x the distance of the required point from the centre A ; then it is easy to find that the portion of spherical surface visible on the first sphere is equal to $\frac{2\pi r^2(x-r)}{x}$, and that visible on the second sphere to $\frac{2\pi r'^2(d-x-r')}{d-x}$; hence the function

of which the maximum is to be found is

$$\frac{r^2(x-r)}{x} + \frac{r'^2(d-x-r')}{d-x} = \frac{-(r^2+r'^2)x^2 + (d(r^2+r'^2) + r^3-r'^3)x - r^3d}{dx - x^2};$$

making the differential coefficient equal to nothing, we have the equation $(r^3 - r'^3)x^2 - 2r^3dx + r^3d^2 = 0$,

which gives $x = \frac{d(r^3 \pm \sqrt{r^3 r'^3})}{r^3 - r'^3}$, or $x = \frac{dr^{\frac{3}{2}}}{r^{\frac{3}{2}} + r'^{\frac{3}{2}}}$, and $x = \frac{dr^{\frac{3}{2}}}{r^{\frac{3}{2}} - r'^{\frac{3}{2}}}$. The first value corresponds to a

Integral
Calculus.

maximum of the function, and is the answer to the question, the second corresponds to a minimum, and must be considered as an analytical solution, since it places the required point not between the two centres, but on the line which joins them produced. The maximum of the function corresponding to the first value is

Part III.

$$2\pi \left\{ r^2 + r'^2 - \left(\frac{r^{\frac{3}{2}} + r'^{\frac{3}{2}}}{d} \right)^2 \right\}.$$

(260.) We shall next consider implicit functions of one variable. Let y represent a function of x given by the equation $y^2 - 2mxy + x^2 - a^2 = 0$. By differentiating we get $(y - mx) dy - (my - x) dx = 0$, and we find $\frac{dy}{dx} = \frac{my - x}{y - mx}$. This being made equal to nothing, gives $my - x = 0$, and to obtain the values of x corresponding to maxima and minima of the function y , this equation must be combined with the proposed equation. We shall have thus

$$y = \frac{x}{m}, \text{ and, by substitution, } \frac{x^2}{m^2} - x^2 - a^2 = 0,$$

from which we get $x = \frac{ma}{\sqrt{1-m^2}}$, $y = \frac{a}{\sqrt{1-m^2}}$. It remains now to examine if the value found for x correspond to a maximum or to a minimum; for that purpose we must find the value of the differential coefficient of the second order $\frac{d^2y}{dx^2}$. We get by differentiating the first differential equation,

$$(y - mx) \frac{d^2y}{dx^2} + \frac{dy^2}{dx^2} - 2m \frac{dy}{dx} + 1 = 0,$$

and this is reduced to $(y - mx) \frac{d^2y}{dx^2} + 1 = 0$, since we have supposed $\frac{dy}{dx} = 0$. Substituting then for y and x , the values $\frac{a}{\sqrt{1-m^2}}$, and $\frac{ma}{\sqrt{1-m^2}}$ we have obtained above, we find $\frac{d^2y}{dx^2} = \frac{-1}{a\sqrt{1-m^2}}$, and this result being negative, shows that the value of y is a maximum.

If we make equal to nothing the denominator of the value $\frac{dy}{dx}$ instead of the numerator, we find $y = mx$, a relation which renders also infinite $\frac{d^2y}{dx^2}$, and all the differential coefficients. It leads to $x = \frac{a}{\sqrt{1-m^2}}$ and $y = \frac{ma}{\sqrt{1-m^2}}$. These values do not differ from the preceding if we change x into y , and y into x , they indicate a maximum of x , which is found under this form, because the proposed equation is symmetrical with respect to its two variables.

(261.) We shall propose, for a second example, to find the maxima and minima of the function y given by the equation $x^3 - 3axy + y^3 = 0$. In this case, y having three values in x , ought to be considered as representing three distinct functions, which, however, are connected together by the character of roots of equations of the third degree; each of these functions may have maxima and minima, as we shall see by the following investigation.

We derive from the given equation $\frac{dy}{dx} = \frac{ay - x^2}{y^2 - ax}$; making $\frac{dy}{dx} = 0$, we shall obtain a new equation $ay - x^2 = 0$, which ought to be combined with the proposed equation to determine the values of x and y . We shall find thus $x^3 - 2a^2x = 0$, from which we get $x^2 = 0$, and $x^3 - 2a^2x = 0$. When we make $x = 0$ we find $y = 0$, and $\frac{dy}{dx} = 0$; to know the signification of the roots of the equation $x^2 = 0$, we must examine what becomes $\frac{d^2y}{dx^2}$ for $x = 0$ and $y = 0$. By differentiating the first differential equation, we find

$$(y^2 - ax) \frac{d^2y}{dx^2} + 2y \frac{dy^2}{dx^2} - 2a \frac{dy}{dx} + 2x = 0.$$

The coefficient of $\frac{d^2y}{dx^2}$ vanishes, since we suppose $x = 0$ and $y = 0$, and the remaining equation of the second degree with respect to $\frac{dy}{dx}$, gives, in the same hypothesis, $\frac{dy}{dx} = 0$, and $\frac{dy}{dx}$ equal to infinity. If we differentiate again, in order to obtain the value of $\frac{d^2y}{dx^2}$, we find

$$(y^2 - ax) \frac{d^3y}{dx^3} + (6y \frac{dy}{dx} - 3a) \frac{d^2y}{dx^2} + 2 \frac{dy^3}{dx^3} + 2 = 0,$$

Integral
Calculus.

which equation, by making at the same time $x = 0$, $y = 0$, and $\frac{dy}{dx} = 0$, gives $\frac{d^2y}{dx^2} = \frac{2}{3a}$, which is a positive quantity, and shows, consequently, that the value $y = 0$ is a minimum value of the function. But if we suppress only, in the equation, the term multiplied by $\frac{d^2y}{dx^2}$, and if we make $\frac{dy}{dx} = p$, we find

$$\frac{d^2y}{dx^2} = -\frac{2 + 2p^3}{6yp - 3a} = -\frac{\frac{2}{p^3} + 2}{\frac{6y}{p^3} - \frac{3a}{p^3}},$$

which becomes infinite when we suppose $y = 0$, and p infinite: as these last values render the differential coefficients infinite, they ought, therefore, to be examined, by supposing x equal to a very small quantity, and determining the corresponding value of y , which we shall represent by k . We have then between h and k the

relation $h^3 - 3ahk + k^3 = 0$. From which we get for the three values of k $\frac{h^2}{3a}$, $+\sqrt{3ah}$ and $-\sqrt{3ah}$.

We see then, that the first of these remains a positive quantity whether $x = +h$ or $x = -h$, and, consequently, it has all the characters of a minimum when $h = 0$; it is not the same thing with respect to the other two, $+\sqrt{3ah}$, $-\sqrt{3ah}$, which become imaginary when a negative value is taken for h .

We have besides the equation $x^3 - 2a^3 = 0$, which gives $x = a\sqrt[3]{2}$ and $y = a\sqrt[3]{4}$ in consequence of the equation $ay - x^2 = 0$. If we substitute these values in the general expression of $\frac{d^2y}{dx^2}$, we shall find $\frac{d^2y}{dx^2} = -\frac{2}{a}$, a result showing that the function y has a maximum corresponding to $x = a\sqrt[3]{2}$.

On Maxima and Minima of Functions of several Variables.

(262.) Let us now consider a function of several variables, and let us suppose first, that it contains only two variables x and y . The definitions given (254.) may easily be extended to functions of more than one variable. With respect to functions of two variables, it is evident that we may consider one of them as a constant, and give to the other an infinite number of values, to each of which will correspond one or several values of the proposed function; among these some may be maxima and minima, and nothing is easier than to find them. Since we consider only one of the variables, it will be sufficient to equal to nothing the first differential coefficient with respect to that variable; thus, u being a function of x and y , if we suppose y constant, and if we make $\frac{du}{dx} = 0$, we shall obtain the values of x , which give the greatest and least values of u , among all those which answer to the same value of y . By eliminating x from the function u , by means of the equation $\frac{du}{dx} = 0$, we shall obtain a result which I shall represent by v , and which, containing still the variable y , may have maxima and minima which will be determined by means of the equation $\frac{dv}{dy} = 0$. We may obtain an equation answering the same purpose as $\frac{dv}{dy} = 0$, without eliminating x ; for that, it is necessary to observe that the equation $\frac{du}{dx} = 0$, furnished by the condition of maximum or minimum relative to x , establishes a relation between the variables x and y , so that the first may be considered as a function of the second. Differentiating u , in this hypothesis, we shall have $\frac{1}{dy} du = \frac{du}{dx} \cdot \frac{dx}{dy} + \frac{du}{dy}$, a result which is reduced to $\frac{du}{dy} = 0$, since we have already $\frac{du}{dx} = 0$; the greatest or least values of all the values of u , will answer therefore to some of the values of x and y given by the equations $\frac{du}{dx} = 0$, $\frac{du}{dy} = 0$. These considerations may easily be extended to any number of variables, and it will be proved, in a similar manner, that to obtain the absolute maxima and minima of these functions, it is necessary to equal separately to nothing the differential coefficients of the first order, taken with respect to each of the variables upon which they depend.

(263.) The distinction between maxima and minima presents more difficulties with respect to functions of several variables, than with those of one variable, although the principles upon which this distinction is founded are the same in both cases.

Let u be a function containing any number of variables x, y, z , &c.; if we call a, b, c , the values which answer to one of its maxima or minima, and if we represent by A, B, C, D , &c., F, G, H, I, K, L , &c., what the quantities $u, \frac{du}{dx}, \frac{du}{dy}, \frac{du}{dz}$, &c., $\frac{d^2u}{dx^2}, \frac{d^2u}{dxdy}, \frac{d^2u}{dy^2}, \frac{d^2u}{dxdz}, \frac{d^2u}{dydz}, \frac{d^2u}{dz^2}$, become, when we substitute in it a for x , b for y , c for z , &c., the result of the substitution of $a + h, b + k, c + l$, &c. for x, y, z , &c. in u , will be

$$u' = A + Bh + Ck + Dl + \&c.$$

$$+ \frac{1}{1.2} (Fh^2 + 2Ghk + Hk^2 + 2Ihl + 2Kkl + Ll^2 + \&c.)$$

$$+ \&c.$$

An expression of which the value ought to be less than A , when that quantity is a maximum of u , and less when it is a minimum, whatever be the signs of $h, k, l, \&c.$, provided however they are taken sufficiently small.

This understood, if we take $k = ah, l = \beta h, \&c.$ we shall find

$$u' - u = h(B + Ca + D\beta + \&c.) + \frac{h^2}{1.2} (F + 2Ga + Ha^2 + 2I\beta + 2Ka\beta + L\beta^2 + \&c.) + \&c.$$

We see that by taking h , and consequently kl , sufficiently small, it is possible to make $h(B + Ca + D\beta + \&c.)$ greater than all the rest of the series; but this quantity changing its sign at the same time as h , a reasoning similar to that used before, will show that $B + Ca + D\beta + \&c.$ ought to be equal to nothing in the case of a maximum or a minimum. Hence the values of $x, y, z, \&c.$ corresponding to a maximum or a minimum ought to

satisfy the equations $\frac{du}{dx} = 0, \frac{du}{dy} = 0, \frac{du}{dz} = 0, \&c.$, a condition which has already been established in the preceding number. It is necessary, moreover, that these same values should not render nothing, at the same time, all the terms of the second order, that is to say, that we should not have at the same time $F = 0, G = 0, \&c. \dots L = 0$. But this is not sufficient, the sign of this quantity of the second order should also be independent of the values and relations which may be established between the quantities $h, k, l, \&c.$, and of the signs they may have.

Now it is known by the general theory of equations, that when all the terms of an equation are on one side, the results of the substitutions of a series of particular values in that side cannot be of different signs, without there existing intermediate particular values, which render that side equal to nothing; and, consequently, if the equation have only imaginary or equal roots, whatever be the values substituted, the result of the substitution will always have the same sign. Let us first find the conditions which ought to be satisfied in order that the quantity

$$Fh^2 + 2Ghk + Hk^2 + 2Ihl + 2Kkl + Ll^2 + \&c.$$

being made equal to nothing and resolved as an equation with respect to one of the quantities $h, k, l, \&c.$ should have only imaginary roots. Let us take, for instance, the value of h , we shall have

$$h = \frac{-(Gk + Il + \&c.) \pm \sqrt{-(Hk^2 + 2Hkl + Ll^2 + \&c.)F + (Gk + Il + \&c.)^2}}{F},$$

this result will be imaginary, if the quantity under the radical be negative; but we may give to this quantity the form $-(Pk^2 + 2Qkl + Rl^2 + \&c.)$, by making $FH - G^2 = P, KF - GI = Q, IF - I^2 = R, \&c.$, and in order that it should not change sign, it will be necessary that being equalled to nothing, and resolved with respect to one of the letters $k, l, \&c.$, it should have only imaginary roots. By these operations, we shall get

$$K = \frac{-(Ql + \&c.) \pm \sqrt{(Rl^2 + \&c.)P + (Ql + \&c.)^2}}{P};$$

and again k can only be imaginary when the quantity under the radical is always negative; it may be put under the form $-(Tl^2 + \&c.)$ by making $PR - Q^2 = T, \&c.$, and then treated in the same manner as the two preceding. The same process may be continued till we come to the last but one of the quantities h, k, l . Let us suppose that there are only three variables in the function u , the operation will be terminated at the value of k ; and since T must be positive, it will be necessary that we should have $PR - Q^2$, or $T > 0$. This condition being fulfilled, the quantity $PK^2 + 2Qkl + Rl^2$ cannot change sign, and as it is reduced to PR^2 when $l = 0$, it is necessary in order that it should remain positive, as it is required by the nature of the question, that we should have $P > 0$, or $FH - G^2 > 0$. Hence we see that the coefficients F and H should be positive at the same time, or negative at the same time: in the first case, the quantity $Fh^2 + \&c.$ preserving always the positive sign it has when k and l are equal to nothing, indicates a minimum; it would be a maximum if that quantity were negative.

It may be easily verified that when the conditions we have just found are fulfilled, the terms of the second order of the series $A + Bh + Ck + \&c.$ will have always the same sign, whatever be the values of $h, k, l, \&c.$ It is sufficient to remark, for that purpose, that the equation of the second degree of which the roots are $t = -a \pm \sqrt{-\beta^2}$ is $(t + a)^2 + \beta^2 = 0$, and if we represent by $-Y^2, -Z^2$, the quantities which are under the radicals of the values of $h, k, \&c.$, we shall transform the expressions

$$\left. \begin{array}{l} Fh^2 + 2Ghk + \dots + Ll^2 + \&c. \\ Pk^2 + 2Qkl + Rl^2 + \&c. \dots \text{or } Y^2 \\ \&c. \end{array} \right\} \text{ into } \left\{ \begin{array}{l} F \left\{ \left(h + \frac{Gk + Il + \&c.}{F} \right)^2 + \frac{Y^2}{F^2} \right\} \\ P \left\{ \left(k + \frac{Ql + \&c.}{P} \right)^2 + \frac{Z^2}{P^2} \right\} \\ \&c. \end{array} \right.$$

Putting in Y^2 , for Z^2 its value $Tl^2 + \&c.$, and substituting the result in $F \left\{ \left(h + \frac{Gk + Il + \&c.}{F} \right)^2 + \frac{Y^2}{F^2} \right\}$, we

$$F\left(h + \frac{Gk + Il + \&c.}{F}\right)^2 + \frac{FP}{F^2}\left(k + \frac{Ql + \&c.}{P}\right)^2 + \frac{FPT}{F^2P^2}\left(l + \frac{\&c.}{T}\right)^2 + \&c.,$$

an expression which, it is obvious, will preserve the same sign whatever be the values of $h, k, l, \&c.$, and the sign of which will only depend on that of F , since P and T are positive.

If u contained only two variables, the coefficients $D, \dots, I, K, L, \&c.$ would be equal to nothing, and the conditions of maximum and minimum would be reduced to $FH - G^2 > 0$, the maximum taking place when F is negative, and the minimum in the contrary case. If the coefficients of the second order were equal to nothing at the same time as those of the first, there would be neither maximum nor minimum, unless the coefficients of the third order disappeared at the same time, and unless the terms of the fourth order formed a quantity whose sign would not depend in any way upon $h, k, l, \&c.$

(264.) We have hitherto omitted the case in which the quantity of the second order does not change sign, not because it has only imaginary roots, but because it has only equal roots. To simplify, we shall suppose that the function u contains only two variables, x and y . In that case, the function which ought not to change sign, whatever be the values of h and k , is $Fh^2 + 2Ghk + Hk^2$. It may be put under the following form,

$$h^2\left\{F + 2G\frac{k}{h} + H\frac{k^2}{h^2}\right\} = h^2\{F + 2Ga + Ha^2\} = Hh^2\left\{\left(\frac{G}{H} + a\right)^2 + \frac{FH - G^2}{H^2}\right\},$$

by making $\frac{k}{h} = a$. It will remain of the same sign as H , not only when we have $FH > G^2$, but also when

$FH = G^2$, because it becomes then $Hh^2\left(\frac{G}{H} + a\right)^2$. The condition $FH = G^2$ takes place when the equations

$\frac{du}{dx} = 0, \frac{du}{dy} = 0$, obtain in consequence of a common factor between the two quantities $\frac{du}{dx}$ and $\frac{du}{dy}$, in which

case the determination of the maxima and minima is an indeterminate problem, since the two equations $\frac{du}{dx} = 0$,

and $\frac{du}{dy} = 0$, by means of which the values of x and y are to be determined, are reduced to one. If we suppose

for instance $\frac{du}{dx} = PV, \frac{du}{dy} = QV$, it will be sufficient to make $V = 0$ to satisfy the two conditions of maximum or minimum. We shall have

$$\frac{d^2u}{dx^2} = V\frac{dP}{dx} + P\frac{dV}{dx}, \quad \frac{d^2u}{dy^2} = V\frac{dQ}{dy} + Q\frac{dV}{dy}, \quad \frac{d^2u}{dxdy} = V\frac{dP}{dy} + P\frac{dV}{dy}, \quad \frac{d^2u}{dxdy} = V\frac{dQ}{dx} + Q\frac{dV}{dx},$$

and by making $V = 0$, they are reduced to

$$F = P\frac{dV}{dx}, \quad H = Q\frac{dV}{dy}, \quad G = P\frac{dV}{dy}, \quad G = Q\frac{dV}{dx},$$

from which results the relation $FH = G^2$.

It is necessary to remark that when the equation $FH = G^2$ subsists at the same time as $V = 0$, the total differential $d^2u, d^3u, \&c.$ *ad infinitum*, vanish as soon as we introduce into it the relation given by the equation $dV = 0$. This is easily proved, for if we consider y as a function of x , we have

$$d^2u = \frac{d^2u}{dx^2}dx^2 + 2\frac{d^2u}{dxdy}dxdy + \frac{d^2u}{dy^2}dy^2 + \frac{du}{dy}d^2y,$$

and since in the present case $\frac{du}{dy} = 0$, this expression of d^2u will be reduced, in making use of the same letters as above, to

$$d^2u = Fdx^2 + 2Gdxdy + Hdy^2 = Hdx^2\left\{\left(\frac{G}{H} + \frac{dy}{dx}\right)^2 + \frac{FH - G^2}{H^2}\right\};$$

but $FH = G^2$, therefore $d^2u = Hdx^2\left(\frac{G}{H} + \frac{dy}{dx}\right)^2 = \frac{1}{H}(Gdx + Hdy)^2$. Substituting between the brackets the values of G and H in the supposition of $V = 0$, we find

$$d^2u = \frac{Q^2}{H}\left(\frac{dV}{dx}dx + \frac{dV}{dy}dy\right)^2 = \frac{Q^2}{H}dV^2,$$

an expression which becomes nothing when $dV = 0$.

It follows from what precedes, that the equation $V = 0$ renders the values of the function u constant; but without this condition d^2u is not equal to nothing, and its sign depends only upon that of H : thus for every value of the variables x and y , which differs from those which satisfy the equation $V = 0$, there will be a decrease of the value of u if H be negative, and increase if it be positive, therefore u will be a maximum in the first case, and a minimum in the second. Consequently there will exist an infinite number of systems of values of x and y which will render at the same time the function u either a maximum or a minimum.

(265.) There exist also with respect to functions of several variables, maxima and minima corresponding to

Integral Calculus. Part III. values of the variables which render the differential coefficients infinite. This is the case for the function

$u = b - (x^2 + y^2)^{\frac{1}{3}}$. It is obvious that whatever be the values substituted for the variables x and y , the result of the substitution will be less than that obtained by supposing $x = 0$ and $y = 0$; this last value $u = b$ is therefore a maximum, and the differential coefficients

$$\frac{du}{dx} = \frac{-2x}{3(x^2 + y^2)^{\frac{2}{3}}}, \quad \frac{du}{dy} = \frac{-2y}{3(x^2 + y^2)^{\frac{2}{3}}},$$

become infinite for $x = 0$ and $y = 0$.

Hence to complete the rules given for the research of maxima and minima with respect to functions of several variables, it would be necessary to add remarks analogous to those which have been made relatively to the determination of the maxima and minima of functions of one variable. But we shall simply observe that, in this case, the maxima and minima are known, because the decrease or increase of the proposed function produced by the substitution of $a + h$, and $b + k$ for x and y may be expressed in such a manner that the whole of it, or at least its most considerable part, does not change sign at the same time as the quantities h and k . In the example

given above, we have by that substitution $u' - u = -(h^2 + k^2)^{\frac{1}{3}}$, a quantity which does not alter its sign. We shall now give a few examples of the maxima and minima of functions of several variables.

Example 1. Let it be proposed to divide a quantity a into three parts x , y and $a - x - y$ such that the product $u = x^m y^n (a - x - y)^p$ shall be a maximum or a minimum.

The differential coefficients of the first order being made equal to nothing, give

$$\frac{du}{dx} = x^{m-1} y^n (a - x - y)^{p-1} \{ma - mx - my - px\} = 0, \quad \frac{du}{dy} = x^m y^{n-1} (a - x - y)^{p-1} \{na - nx - ny - py\} = 0;$$

the factors $ma - mx - my - px$, and $na - nx - ny - py$, being put equal to nothing, give two equations from which the values of x and y may be derived; and thus we find

$$x = \frac{ma}{m+n+p}, \quad y = \frac{na}{m+n+p}, \quad a - x - y = \frac{pa}{m+n+p}.$$

In order to discover whether these correspond to a maximum or a minimum, we must substitute them in the values of $\frac{d^2u}{dx^2}$, $\frac{d^2u}{dy^2}$, $\frac{d^2u}{dxdy}$, and if $m+n+p$ be represented by q , we shall get

$$F = -(m+p) \left(\frac{ma}{q}\right)^{m-1} \left(\frac{na}{q}\right)^n \left(\frac{pa}{q}\right)^{p-1}, \quad G = -\frac{mna}{q} \left(\frac{ma}{q}\right)^{m-1} \left(\frac{na}{q}\right)^{n-1} \left(\frac{pa}{q}\right)^{p-1}, \\ H = -(n+p) \left(\frac{ma}{q}\right)^m \left(\frac{na}{q}\right)^{n-1} \left(\frac{pa}{q}\right)^{p-1}.$$

The quantities F and H are both negative, and it will be easy to verify that they satisfy also the condition $FH - G^2 > 0$, and, therefore, the corresponding value of the function is a maximum.

Example 2. To find the greatest triangle which can be included within a given perimeter.

Let the perimeter be $2a$, the sides x , y and $2a - x - y$, we shall have in representing the area by u ,

$$u = \sqrt{a(a-x)(a-y)(x+y-a)},$$

and by taking the logarithms of both sides of this equation,

$$2 \log u = \log a + \log(a-x) + \log(a-y) + \log(x+y-a);$$

differentiating for x and y , we find

$$2 \frac{du}{u} = -\frac{dx}{a-x} + \frac{dx}{x+y-a}, \quad \text{from which we derive } \frac{du}{dx} = \frac{1}{2} u \frac{2a-2x-y}{(a-x)(x+y-a)}; \quad \text{in the same manner}$$

$$\text{we shall find } \frac{du}{dy} = \frac{1}{2} u \frac{2a-2y-x}{(a-y)(x+y-a)}. \quad \text{Putting equal to nothing these two partial differential coefficients,}$$

we get the two equations $2a - 2x - y = 0$, $2a - 2y - x = 0$, which being resolved, give $x = \frac{2}{3}a$,

$y = \frac{2}{3}a$, $a - x - y = \frac{2}{3}a$. These values being substituted in the differential coefficients of the second order,

will be found to satisfy the conditions of a maximum. Therefore they correspond to a maximum, and the required triangle is equilateral.

Example 3. Let the proposed function $u = x^4 + y^4 - ax^2y - axy^2 + c^2x^2 + c^2y^2$, then

$$\frac{du}{dx} = 4x^3 - 2axy - ay^2 + 2c^2x = 0, \quad \frac{du}{dy} = 4y^3 - 2axy - ax^2 + 2c^2y = 0.$$

If we subtract these equations from each other, we find $4(x^3 - y^3) + a(x^2 - y^2) + 2c^2(x - y) = 0$, of which equation $x - y$ is a factor: consequently, $y = x$, and $4x^3 - 3ax^2 + 2c^2x = 0$; which gives

Integral
Calculus.

$$x = 0, \text{ and } x = \frac{3a \pm \sqrt{(9a^2 - 32c^2)}}{8}.$$

If $x = 0$, and $y = 0$, we have $F = 2c^2$, $G = 0$, $H = 2c^2$, the condition $FH - G^2 > 0$ is satisfied, and F is a positive quantity, therefore the values $x = 0$ and $y = 0$ correspond to a minimum value of the function, which is equal to nothing.

$$\text{If } x = \frac{3a + \sqrt{(9a^2 - 32c^2)}}{8} = y, \text{ we find } F = \frac{21a^2 - 32c^2 + 7a\sqrt{(9a^2 - 32c^2)}}{8} = H, \text{ and}$$

$G = \frac{12a^2 + 4a\sqrt{(9a^2 - 32c^2)}}{8}$: these values give $FH - G^2 > 0$, since we suppose $9a^2 > 32c^2$. For the same reason F is positive, therefore the values of x and y correspond also to a minimum value of u , and we have

$$u = -\frac{27}{256}a^4 + \frac{9}{16}a^2c^2 - \frac{1}{2}c^4 - \frac{a}{256}(9a^2 - 32c^2)^{\frac{3}{2}}.$$

$$\text{If } x = \frac{3a - \sqrt{(9a^2 - 32c^2)}}{8} = y, \text{ we have } F = \frac{21a^2 - 32c^2 - 7a\sqrt{(9a^2 - 32c^2)}}{8} = H, \text{ and}$$

$$G = -\frac{12a^2 - 4a\sqrt{(9a^2 - 32c^2)}}{8}.$$

These values give $FH < G^2$; in this case, therefore, the value of u corresponding to the values of x and y is neither a maximum nor a minimum.

If we consider the other factor of $\frac{du}{dx} - \frac{du}{dy} = 0$, or $4x^3 + 4xy + 4y^3 - ax - ay + 2c^2 = 0$, and eliminate y from this equation, and the equation $\frac{du}{dx} = 0$, we shall get a final equation of six dimensions, the solution of which would be required in order to determine the other values of x and y .

Example 4. Let the proposed function be $u = \frac{2^4 acxyz}{(a+x)(x+y)(y+z)(z+c)}$. Considering $\log u = u'$, as the function, and making $\frac{du'}{dx} = 0$, $\frac{du'}{dy} = 0$, $\frac{du'}{dz} = 0$, we get $ay = x^2$, $xz = y^2$, $ey = z^2$, or $a : x :: x : y :: y : z :: z : e$ and $x = a \sqrt[4]{\frac{e}{a}} = am$, $y = am^2$, and $z = am^3$, if $m = \sqrt[4]{\frac{e}{a}}$. Again, if we put $a^2m(1+m^2) = A$, we find

$$F = \frac{d^2u'}{dx^2} = -\frac{2}{A}, \quad G = \frac{d^2u'}{dx dy} = \frac{1}{mA}, \quad H = \frac{d^2u'}{dy^2} = -\frac{2}{m^2A}, \quad K = \frac{d^2u'}{dy dz} = \frac{1}{m^2A},$$

$$L = \frac{d^2u'}{dz^2} = -\frac{2}{m^4A}, \quad I = \frac{d^2u'}{dx dz} = 0,$$

consequently $(FH - G^2)(LF - I^2) = \frac{12}{m^6A^4}$, and $KF - GI = -\frac{2a}{m^3A^3}$; therefore $(DF - E^2)(DH - K)$

$> (DG - EK)^2$, and the value of u' and therefore of u determined by this process is a maximum.

Example 5. Let the proposed function be $u = (x+1)(y+1)(z+1)$; the variables being connected by the equation $a^x b^y c^z = A$. Eliminating z we find $u = (x+1)(y+1) \left\{ 1 + \frac{\log A}{\log c} - \frac{y \log b}{\log c} - \frac{x \log a}{\log c} \right\}$; and

making $\frac{du}{dx} = 0$, and $\frac{du}{dy} = 0$, we get

$$\left\{ 1 + \frac{\log A}{\log c} - \frac{y \log b}{\log c} - \frac{x \log a}{\log c} \right\} - (x+1) \frac{\log a}{\log c} = 0, \text{ and } 1 + \frac{\log A}{\log c} - \frac{y \log b}{\log c} - \frac{x \log a}{\log c} - (y+1) \frac{\log b}{\log c} = 0.$$

These two equations give $a^{x+1} = b^{y+1}$, and in an analogous manner we should find $a^{x+1} = c^{z+1}$. These two equations combined with the equation $a^x b^y c^z = A$, after having multiplied both sides by abc , give

$$x = \frac{\log bcA - 2 \log a}{3 \log a}, \quad y = \frac{\log acA - 2 \log b}{3 \log b}, \quad z = \frac{\log abA - 2 \log c}{3 \log c}.$$

We have then

$$\frac{d^2u}{dx^2} = -2(y+1) \frac{\log a}{\log c}, \quad \frac{d^2u}{dx dy} = -(x+1) \frac{\log a}{\log c} + 1 + \frac{\log A}{\log c} - \frac{y \log b}{\log c} - \frac{x \log a}{\log c} - (y+1) \frac{\log b}{\log c},$$

$$\frac{d^2u}{dy^2} = -2(x+1) \frac{\log b}{\log c}.$$

Substituting in these the values of x and y , we shall find that the condition $FH - G^2 > 0$ is satisfied, and as F is negative, these values correspond to a maximum of $u = \frac{(\log \sqrt[3]{abcA})^3}{\log a \log b \log c}$.

(266.) The Differential and Integral Calculus furnishes methods to discover the properties of curve lines and curve surfaces, and to resolve geometrical problems, which are far more general and simple than those derived from geometrical considerations alone, or founded on common algebra. These methods, and the most interesting results to which they have led, will form the subject of the following pages.

We shall begin by the application of the Differential Calculus to the geometry of plane curves, and the first problem we shall propose to resolve will be to find the equation of a straight tangent, from a given point, to a curve given by its equation referred to rectangular coordinates.

By a tangent to a plane curve, we understand a straight line passing through one of the points of the curve which is called the point of contact, and such that no other straight line can be drawn through the same point, passing between the curve and the tangent, immediately after or immediately before the point of contact.

This understood, let AX, AY , (fig. 1,) be the axes of coordinates, MN the curve, M the point of contact, and MT the tangent. There are generally two different cases which may occur: the curve may turn its convexity towards the axis of x , as in fig. 1, and be, immediately about the point of contact, above its tangent with respect to that axis; or it may, on the contrary, turn its concavity towards the axis of x , and be under its tangent, immediately about its point of contact. Our reasonings will only apply to the first case, but it will be extremely simple to see how it ought to be modified to be applied to the second. The cases which are not included under these two will be considered afterwards separately. Let $y = f(x)$ be the equation of the curve, and $x' = AP$, and $y' = MP$, be the coordinates of the point of contact. Then $y' = f(x')$; and if we substitute $x' + h$ for x in the equation $y = f(x)$ and represent the corresponding value of y by $y' + k$, we shall have, in the supposition that $f(x' + h)$ may be developed according to the integral powers of h ,

$$y' + k = y' + \frac{dy'}{dx'} \cdot h + \frac{d^2y'}{dx'^2} \cdot \frac{h^2}{1.2} + \frac{d^3y'}{dx'^3} \cdot \frac{h^3}{1.2.3} + \&c.$$

$\frac{dy'}{dx'}$, $\frac{d^2y'}{dx'^2}$, $\frac{d^3y'}{dx'^3}$, designating the values of $\frac{dy}{dx}$, $\frac{d^2y}{dx^2}$, $\frac{d^3y}{dx^3}$, &c. corresponding to $x = x'$. By taking h sufficiently small, $x' + h$ and $y' + k$ will represent the coordinates of a point of the curve taken as near the point of contact as we choose. Let N be that point, then $x' + h = AS$, $y' + k = NS$.

The equation of any straight line, such as $MN''n''$, drawn through the point M , will be of the form $y - y' = a(x - x')$, a being the tangent of the angle which it makes with the axis of the X . If in that equation we substitute $x' + h$ for x , the corresponding value of y will be the ordinate of the point where $MN''n''$ meets NS . Let N'' be that point, we shall have $N''S - y' = a(x' + h - x')$ or $N''S = y' + ah$. This value being compared with that of NS , gives

$$NS - N''S = \left(\frac{dy'}{dx'} - a \right) h + \frac{d^2y'}{dx'^2} \cdot \frac{h^2}{1.2} + \&c.$$

Now if MT be, as we have supposed, the tangent to the curve, the value of a which corresponds to it should be such as to render either the difference $NS - N''S = NN''$, which then becomes $NS - N'S = NN'$ less for any small value of h , positive or negative, than the value of this difference corresponding to any other value of a , or of a contrary sign to it. But it is obvious that the only way of satisfying this condition is to make the value

of a corresponding to $MT = \frac{dy'}{dx'}$, for then the difference $NS - N'S$ will be equal to $\frac{d^2y'}{dx'^2} \frac{h^2}{1.2} + \frac{d^3y'}{dx'^3} \frac{h^3}{1.2.3} + \&c.$

whilst for any other straight line, such as $MN''n''$, the difference will be $\left(\frac{dy'}{dx'} - a \right) h + \frac{d^2y'}{dx'^2} \cdot \frac{h^2}{1.2} + \frac{d^3y'}{dx'^3} \frac{h^3}{1.2.3} + \&c.$ This last series, by taking h sufficiently small, will always be greater than the first, or of a contrary sign to it. Hence the value of the tangent of the angle which MT makes with the axis of the X is equal to

$\frac{dy'}{dx'}$, and the equation of the tangent to the curve is $y - y' = \frac{dy'}{dx'} (x - x')$.

(267.) The consideration of infinitely small quantities, which in general considerably simplifies the applications of the Differential and Integral Calculus to Geometry, leads to the important result we have just obtained in a much easier manner. A curve, according to that doctrine, is considered as a polygon of an infinite number of infinitely small sides. Each of these sides is called an element of the curve, and one of these elements produced becomes a tangent to the curve. Hence if x', y' represent the coordinates of one of the extremities of an element $x' + dx', y' + dy'$ will be the coordinates of the other extremity, and the equation of the line passing

through these two points or the tangent, will therefore be $y - y' = \frac{dy'}{dx'} (x - x')$. If $\frac{dy'}{dx'} = 0$ the tangent is parallel

to the axis of x , if it be infinite, the tangent is perpendicular to the same axis.

(268.) We have found for the difference between the ordinate of a point of the curve very near the point of contact, and the corresponding ordinate of the tangent, the expression

$$\frac{d^2y'}{dx'^2} \frac{h^2}{1.2} + \frac{d^3y'}{dx'^3} \cdot \frac{h^3}{1.2.3} + \&c.$$

Integral
Calculus.

$x' + h$ being the abscissa of the point we consider. By taking h sufficiently small the sign of the whole series will only depend upon the sign of the first term, that is upon the sign of $\frac{d^2 y'}{d x'^2}$. Hence it is obvious that when this differential coefficient is positive, the curve is above its tangent with respect to the axis of x , and below when it is negative; it would be precisely the reverse if the ordinate of the point we consider were negative. Therefore by the sign of $\frac{d^2 y'}{d x'^2}$ we shall be able to determine whether, at the point whose coordinates are x' and y' , it is the concavity or convexity of the curve which is turned towards the axis of the x ; when y' and $\frac{d^2 y'}{d x'^2}$ have both

the same sign, it is the convexity, and when of contrary signs, it is the concavity which is turned towards that axis. (269.) The equation of the tangent being once determined, there is no difficulty in finding the equation of the normal MR , and the values of the subtangent PT , subnormal PR , as well as those of the lengths MT and MR of the tangent and normal comprised between the point of contact and the axis of x . We shall have

respectively, for the normal, $y - y' = -\frac{d x'}{d y'}(x - x')$; and $PT = y' \frac{d x'}{d y'}$, $PR = y' \frac{d y'}{d x'}$,

$$MT = y' \sqrt{1 + \frac{d x'^2}{d y'^2}}, \text{ and } MR = y' \sqrt{1 + \frac{d y'^2}{d x'^2}}.$$

(270.) The application of these general formulæ to particular examples does not present the least difficulty, for it will be sufficient, in each case, to substitute for $\frac{d y}{d x}$ and $\frac{d x}{d y}$, their values derived from the differential equation of the proposed equation. The general equation of the curves of the second degree is $y^2 = m x + n x^2$, the differential of this is $2 y d y = m d x + 2 n x d x$, and, therefore, $\frac{d y}{d x} = \frac{m + 2 n x}{2 y}$. Consequently the equations of the tangent and the normal in any point of which the coordinates are x' and y' , will be respectively

$$y - y' = \frac{m + 2 n x'}{2 y'}(x - x'), \quad y - y' = \frac{-2 y'}{m + 2 n x'}(x - x').$$

In the same manner we shall have for the values of the subtangent, subnormal, tangent, and normal, respectively, the following values

$$\frac{2(m x' + n x'^2)}{m + 2 n x'}, \quad \frac{m + 2 n x'}{2}, \quad \sqrt{\left\{m x' + n x'^2 + 4 \left(\frac{m x' + n x'^2}{m + 2 n x'}\right)^2\right\}}, \quad \sqrt{\left\{m x' + n x'^2 + \frac{1}{4}(m + 2 n x')^2\right\}}.$$

We have supposed in what precedes, that the axes of coordinates were at right angles, but it is easy to see that if they were not so, the equation of the tangent would still preserve the same form, and the only difference would be that $\frac{d y'}{d x'}$ instead of being equal to the trigonometrical tangent of the angle, which the tangent to the curve makes with the axis of the x , would be equal to the ratio of the sines of the angles which this same line makes with both the axis of x and the axis of y .

On Asymptote to plane Curve Lines.

(271.) When a straight line approaches indefinitely to a curve without ever meeting it, this straight line is called an *asymptote* to the curve. It is easy to find the asymptotes of a curve represented by an equation between two rectangular coordinates x and y . Let us first consider the asymptotes which are not parallel to the axis of the y , and let $y = k x + l$ be the equation of one of them. The ordinate corresponding to the abscissa x in the proposed curve, ought to reduce itself sensibly, for very large numerical values of x , to the ordinate of the asymptote, and to present itself under the form $y = k x + l \pm \epsilon$, $\pm \epsilon$ being a term which becomes nothing when

$\frac{1}{x} = 0$. This understood, since from the equation $y = k x + l \pm \epsilon$, we get $\frac{y}{x} = k + \frac{l \pm \epsilon}{x}$, and also $y - k x = l \pm \epsilon$,

it is obvious that for increasing values of x the limit of $\frac{y}{x}$ is equal to k , and the limit of $y - k x = l$. Hence, to deter-

mine the constant k , it will be sufficient to write $\frac{y}{x} = s$ or $y = s x$, in the equation of the curve, and to find the limit or limits of the variable s , for indefinitely increasing values of x . Then, the constant k having been thus determined, we shall obtain the value of l by making in the equation of the curve $y - k x = t$, or $y = k x + t$, and finding the limit of t for indefinitely increasing values of x . To each system of finite values of the quantities k and l will correspond an asymptote of the proposed curve.

By a similar reasoning, and changing x into y and y into x , we shall obviously find the asymptotes which are not parallel to the axis of x .

Let us take for first example the curve called *logarithmic*, the equation of which is $y = a^x$. We shall have

Part III.
Integral
Calculus.

Part III.

then $s = \frac{y}{x} = \frac{A^x}{x}$. For increasing positive values of x the expression $\frac{A^x}{x}$ has no limit, but on the contrary for increasing negative values of x the limit is clearly $= 0$. Therefore in this case $k = 0$; and we shall have simply $t = y = A^x$, the limit of which for increasing negative values of x is equal to nothing. Consequently the equation of the asymptote is $y = 0$, which equation belongs to the axis of the x , and it is even only the negative part of that axis which is asymptote to the curve. In the same manner it might be proved that the logarithmic $x = A^y$, has for asymptote the axis of the y .

Let us suppose now that the equation of the curve presents itself under the form $f(x, y) = c$, c being a constant quantity. The determination of the asymptotes will be very easy, if we can decompose $f(x, y)$ into several parts, each of which is an homogeneous function of x and y . Let m, n , &c. be the degrees of these homogeneous functions, and let

$$f(x, y) = x^m \phi\left(\frac{y}{x}\right) + x^n \psi\left(\frac{y}{x}\right) + \&c.$$

The numbers m, n , &c. being ranged in a decreasing order. If we make $\frac{y}{x} = s$, the value of s will be determined by the equation

$$x^m \phi(s) + x^n \psi(s) + \&c. = c, \quad \text{or } \phi(s) + \frac{1}{x^{m-n}} \psi(s) + \&c. = \frac{c}{x^m},$$

from which we shall get, by making $\frac{1}{x} = 0$, and $s = k$, $\phi(k) = 0$. Moreover, if we take for k one of the roots of the equation $\phi(k) = 0$, the corresponding value of $t = y - kx$ will be given by the formula

$$x^m \phi\left(k + \frac{t}{x}\right) + x^n \psi\left(k + \frac{t}{x}\right) + \&c. = c.$$

But since $\phi(k) = 0$, we may assume $\phi\left(k + \frac{t}{x}\right) = \frac{t}{x} \phi'(k + \theta \frac{t}{x})$, ϕ' being the characteristic of the function of k , which is the differential coefficient of $\phi(k)$, and θ being a number less than one. We shall have therefore

$$x^{m-1} t \phi'\left(k + \theta \frac{t}{x}\right) + x^n \psi\left(k + \frac{t}{x}\right) + \&c. = c, \quad \text{or } t \phi'\left(k + \theta \frac{t}{x}\right) + \frac{1}{x^{m-n-1}} \psi\left(k + \frac{t}{x}\right) + \&c. = \frac{c}{x^{m-1}}.$$

If $\phi'(k)$ and $\psi(k)$ have finite values, not equal to nothing, then by making $\frac{1}{x} = 0$, and $t = l$, we shall find by means of the preceding equation

$$1. \quad \text{when } n < m - 1, l = 0; \text{ for } n = m - 1, l = -\frac{\psi(k)}{\phi'(k)}; \text{ and for } n > m - 1, l = \pm \infty.$$

Consequently the root of the equation $\phi(k) = 0$, which has been taken for k , will correspond, in the first case, to an asymptote passing through the origin of the coordinates, which will have for its equation $y = kx$; in the second case to an asymptote having for its equation $y = kx - \frac{\psi(k)}{\phi'(k)}$; and in the third the asymptote being removed to an infinite distance will disappear entirely.

The elimination of the constant k between the equations $\phi(k) = 0$, and $y = kx$, gives $\phi\left(\frac{y}{x}\right) = 0$. This equation, in the first case, will give all the asymptotes not parallel to the axis of y ; instead of it we may use the equation $x^m \phi\left(\frac{y}{x}\right) = 0$; and this is precisely the one we should obtain, by trying to find, in the same case, the asymptotes which are not parallel to the axis of x . Therefore when the left side of the proposed equation of the curve, the right side being a constant quantity, may be decomposed into several homogeneous functions, and when the degree m of one of them is greater by more than one unity than the degrees of all the others, not only all the asymptotes pass through the origin, but they are all represented by the formula obtained in making equal to nothing the homogeneous function of the m^{th} degree.

Let us illustrate these rules by a few examples. The equation of an hyperbola referred to its axis is $\frac{x^2}{a^2} - \frac{y^2}{b^2} = \pm 1$; it has, therefore, for asymptotes the two straight lines represented by the equation $\frac{x^2}{a^2} - \frac{y^2}{b^2} = 0$, or which is the same thing, by the two equations $\frac{x}{a} - \frac{y}{b} = 0$, $\frac{x}{a} + \frac{y}{b} = 0$.

In the same manner it is easy to see that, if we have $B^2 - Ac > 0$, the hyperbola having for its equation $Ax^2 + 2Bxy + Cy^2 = K$, will have for asymptotes the two straight lines represented by the equation $Ax^2 + 2Bxy + Cy^2 = 0$, that is to say, by the two equations $y = -\frac{Bx}{c} + \frac{x}{c} \sqrt{(B^2 - Ac)}$, $y = -\frac{Bx}{c} - \frac{x}{c} \sqrt{(B^2 - Ac)}$.

In the same manner, again, the curve represented by the equation $x^3 + y^3 + \sin \frac{y}{x} = 0$, will have for its asymptote the straight line having for equation $x + y = 0$, the ordinate of which is the only real value of y , which satisfies the equation $x^3 + y^3 = 0$.

In the case where $n = m - 1$, the equation $x^m \phi\left(\frac{y}{x}\right) = 0$ represents all the straight lines drawn through the origin, parallel to the asymptotes of the curve. Thus for instance, the curve called *folium of Descartes*, and represented by the equation $x^3 + y^3 = 3axy$, has an asymptote parallel to the straight line, of which the equation is $x + y = 0$, equation derived as above from $x^3 + y^3 = 0$; the equation of the asymptote is $y = -x + 1$.

When the quantities $\phi'(k)$ and $\psi(k)$ become infinite or equal to nothing, the quantity l may have values different from those given above; but to determine then the value of this quantity, it will always be sufficient to find the limit or the limits towards which the quantity t converges, whilst $\frac{1}{x}$ approaches to become equal to nothing for increasing values of x . Sometimes we may find for a single value of k several values of l . This will happen, for instance, if we consider the curve represented by the equation $y^2 = \cos\left(\frac{y}{x}\right)$. We have then $k = 0$; and, as the equation in t becomes $t^2 = \cos\left(\frac{t}{x}\right)$, we shall have by making $\frac{1}{x} = 0$, $t^2 = 1$, $t = \pm 1$. Consequently the proposed curve has two asymptotes parallel to the axis of the x , and represented by the equations $y = 1$ and $y = -1$.

It must, however, be observed, that it may happen that a value of k which verifies the equation $\phi'(k) = 0$ gives a single asymptote. Thus the curve represented by the equation $y^2(x^2 + y^2) = r^4$ has only one asymptote, which coincides with the axis of x .

(272.) The asymptotes of a plane curve may also be found, according to the remark of Ampère, by finding the positions which the tangent takes when the point of contact is situated at an infinite distance from the origin of the coordinates. Let us suppose, for instance, that the curve is an hyperbola represented by the equation $\frac{x^2}{a^2} - \frac{y^2}{b^2} = 1$. The equation of the tangent to this hyperbola will be $\frac{xx'}{a^2} - \frac{yy'}{b^2} = 1$, or if we substitute for $\frac{y'}{b}$ its value $\pm \frac{x'}{a} \sqrt{1 - \frac{a^2}{x'^2}}$, and multiply afterwards by $\frac{a}{x'}$, $\frac{x}{a} \pm \left(1 - \frac{a^2}{x'^2}\right) \frac{y}{b} = \frac{a}{x'}$. To express that the point of contact is situated at an infinite distance from the origin, it will be sufficient to make x equal to plus or minus infinity. Then the preceding formula will become $\frac{x}{a} \pm \frac{y}{b} = 0$, and will be the equations of the two asymptotes of the proposed hyperbola.

(273.) There is another method of determining whether a curve admits a rectilinear asymptote, still founded upon the principle that the tangent becomes an asymptote when the point of contact is infinitely removed. The equation of the tangent through the point whose coordinates are x' and y' , is $y - y' = \frac{dy'}{dx'}(x - x')$.

Let X be the part of the axis of x , intercepted between the origin and the point where the tangent meets the axis of x ; and let Y be the corresponding quantity with respect to the axis of y . It is evident that these quantities will be obtained by making y and x successively $= 0$ in the equation of the tangent. Hence we find $X = \frac{x'dy' - y'dx'}{dy'}$, $Y = \frac{y'dx' - x'dy'}{dx'}$. In these quantities let x' increase indefinitely. If the limits of X and Y with respect to the increase of x be finite, they will determine a rectilinear asymptote. If X have a limit, but Y none, then the asymptote is parallel to the axis of y at the distance X . If Y have a limit, but X none, then the asymptote is parallel to the axis of x at the distance Y . If neither have a limit, or if their values are rendered impossible by increasing x , then the curve has no rectilinear asymptote. If in the limit $X = 0$, $Y = 0$, then there may be an asymptote passing through the origin, and its direction may be found by determining the value of $\frac{dy}{dx}$ when x is infinite.

Let us take as an example of this method the equation $y^2 = mx + nx^2$. We shall easily find

$$X = \frac{xdy - ydx}{dy} = x - \frac{2y^2}{m + 2nx} = \frac{-mx}{m + 2nx}, Y = \frac{ydx - xdy}{dx} = y - \frac{mx + 2nx^2}{2y} = \frac{mx}{2\sqrt{mx + nx^2}}$$

These values may be put under the forms $\frac{-m}{\frac{m}{x} + 2n}$ and $\frac{m}{2\sqrt{\frac{m}{x} + n}}$: consequently their limits for increasing

values of x , or their values when x is infinite, are $-\frac{m}{2n}$, and $\frac{m}{2\sqrt{n}}$. If we had $n = 0$ these quantities, that is both the limits of X and Y would be infinite, and, consequently, in that case, the curve has no rectilinear asymptote, which might be foreseen, since then the curve is a parabola. If n be a negative quantity, one of the limits becomes imaginary, and therefore the curve has no rectilinear asymptote, and in fact in that case the curve is an ellipse.

Part III.
Integral
Calculus.

Part III.

(274.) The consideration of the various developements which may be derived from the equation of a curve, representing the value of the ordinate in a series of terms arranged according to decreasing powers of the abscissa, offers perhaps the most general and satisfactory means to determine the asymptotes of a curve. Let $F(x, y) = 0$, and $f(x, y) = 0$, be the equations of two plane curves having infinite branches, and let y and y_1 be the values of the ordinates in the two curves corresponding to the same abscissa. The distance between the curves measured in a direction parallel to the axis of y is $y - y_1$. If as x increases without limit, either positively or negatively, the distance $y - y_1$ diminishes constantly, but vanishes only when x becomes infinite, then the infinite branch of one of the curves is said to be an asymptote to the other.

In order that this should occur, it is clearly necessary that the quantity $y - y_1$, developed according to the powers of x , should contain only negative powers of x . For if it contained a positive power, $y - y_1$ would be rendered infinite by x becoming infinite, and if it contained a term independent of x it would be finite when x is

infinite. Hence the developement of $y - y_1$ must have the form $Ax^{-\alpha} + Bx^{-\beta} + \&c.$

It follows, therefore, that if the developement of y , according to the descending powers of x , contain any positive powers, or a term independent of x , all these must also occur in the developement of y_1 , in order that they may disappear by subtraction. Hence if the developement of y be $y = A'x^{\alpha'} + B'x^{\beta'} + \dots + M + Ax^{-\alpha} + Bx^{-\beta} + \&c.$

the developement of y_1 must be $y_1 = A'x^{\alpha'} + B'x^{\beta'} + \dots + M + A_1x^{-\alpha_1} + B_1x^{-\beta_1} + \&c.$

Since nothing determines the terms which follow M in the second series, it follows that there may be an infinite number of asymptotes to the same curve, and that each of these will be asymptotes to each other. The most simple asymptote which the curve admits, at least that the developement of which is the simplest, is the curve

represented by the equation $y_1 = A'x^{\alpha'} + B'x^{\beta'} + \dots + M$. The curve represented by $y_2 = A'x^{\alpha'} + B'x^{\beta'} + \dots + M + Ax^{-\alpha}$ is also an asymptote, and approaches closer to the curve than the former, since, by increasing x , it is manifest that y_2 approaches nearer to equality with y than y_1 does. In like manner, the curve represented by $y_3 = A'x^{\alpha'} + B'x^{\beta'} + \dots + M + Ax^{-\alpha} + Bx^{-\beta}$ has asymptotism of a still higher order with the curve.

(275.) Curves which admit asymptotes are sometimes divided into *hyperbolic* and *parabolic*. Hyperbolic are those which admit of rectilinear asymptotes; parabolic, those which do not.

All hyperbolic curves must, therefore, be involved in the class represented by the equation $y = A'x + B' + Ax^{-\alpha} + Bx^{-\beta} + \dots$. The equation of the rectilinear asymptote being $y = A'x + B'$.

To show the application of this method, let the proposed equation be $ax^4 - by^4 + c^2xy = 0$. If we investigate series for y in terms of x , by means of Lagrange's Theorem, we shall find one of them involving descending powers of x , which is

$$y = \frac{a^{\frac{1}{4}}}{b^{\frac{1}{4}}}x + \frac{c^2}{4a^{\frac{1}{2}}b^{\frac{1}{2}}x} - \frac{c^2}{4^2 \cdot 1 \cdot 2b^{\frac{3}{4}} \cdot a^{\frac{5}{4}} \cdot x^3} + \&c.$$

If we confine ourselves to the first term, we shall have a linear equation $y = \frac{a^{\frac{1}{4}}}{b^{\frac{1}{4}}}x$, which belong to the recti-

near asymptote of the curve. If we take two terms of the series, we shall have the equation of a curve, which in this case is an hyperbola, and is a curve asymptote to the proposed curves.

Let us take for a second example the equation $xy^2 - ey = ax^3 + bx^2 + cx + d$. The series which may be obtained for y are

$$y = x\sqrt{a} + \frac{b}{2\sqrt{a}} + \frac{4ac - b^2 + 4ac\sqrt{a}}{8ax\sqrt{a}} + \&c. \quad y = -x\sqrt{a} - \frac{b}{2\sqrt{a}} + \frac{4ac - b^2 - 4ac\sqrt{a}}{8ax\sqrt{a}} - \&c.$$

$$y = \frac{e}{x} + \frac{d}{e} + \frac{cx}{e} + \frac{bx^2}{e} + \&c. \quad \text{and} \quad y = -\frac{d}{e} - \frac{cx}{e} - \frac{bx^2}{e} - \&c.$$

the equations $y = x\sqrt{a} + \frac{b}{2\sqrt{a}}$, and $y = -x\sqrt{a} - \frac{b}{2\sqrt{a}}$ represent two asymptotes which cut the axis of x

at a distance from the origin of the coordinates equal to $\frac{b}{2a}$, and make angles with the same axis whose trigono-

metrical tangents are $\sqrt{a}$ and $-\sqrt{a}$. From the third series, it appears that y is infinite, when $x = 0$, and it is easy to see that the axis of y is likewise an asymptote to the curve. If $b = 0$, these three asymptotes pass through the origin of coordinates. If a be negative, the curve has only one asymptote, the equations for the two first involving imaginary quantities. If $a = 0$, $b = 0$, the two first series for y become

$$y = \sqrt{c} + \frac{e\sqrt{c+d}}{2x\sqrt{e+c}} + \&c. \quad y = -\sqrt{c} + \frac{e\sqrt{c-d}}{2x\sqrt{e+c}} - \&c.$$

and the equations for the two asymptotes are $y = \sqrt{c}$ and $y = -\sqrt{c}$, which correspond to two lines drawn parallel to the axis, at a distance $= \sqrt{c}$ above and below it. If $c = e$, these two asymptotes coincide with the axis, which is therefore an asymptote to the curve.

(276.) If the rules of the Differential Calculus are of little use to find the asymptotes of curves, they are on the contrary employed with some advantage to discover those peculiarities in a curve which are designated under the name of singular and remarkable points.

The points to be considered are: First. Those at which the tangent is parallel to the axis of x or to the axis of y . Secondly. The points at which the curve passes from one side of its tangent to the other, as in fig. 2; such a point is called a *point of inflexion*, and sometimes a *point of contrary flexure*. Thirdly. The points where two branches of a curve meet, being both tangent to the tangent passing through that point, and extending only on one side of the point of contact; such points are called *cusps*: they are *cusps of the first kind*, when the two branches lie at opposite sides of the common tangent, (fig. 3,) and they are *cusps of the second kind*, when the two branches lie at the same side of the tangent. (Fig. 4.) Fourthly. The points through which two or more branches of a curve pass, having all a common tangent at that point, but extending on each side of the point of contact, they may then have their convexities turned towards the same side, or contrary ways; (fig. 5;) such points are called *points of osculation*. Fifthly. The points through which pass two or more branches of a curve, which have not the same tangent at that point; (fig. 6;) such points are called *multiple points*. Sixthly. The points whose coordinates satisfy the equation of the curve, but which, however, are isolated, so that no point of the curve is found immediately near them, on either side; such points are called *conjugate points*. Seventhly. The points where a branch of a curve suddenly stops, extending only on one side of it; (fig. 7;) such points may be called *stop points*. And finally, the points where two or more branches of a curve meet and stop, extending only on one side of that point, and having each a particular tangent; (fig. 8;) such a point may be called a *booting point*.

(277.) The general method to discover whether a point whose coordinates are x' and y' is one of the singular points just mentioned, is to examine attentively the curve immediately before and immediately after the point. This may be done generally by substituting $x' + h$ for x in the equation of the curve, and developing the corresponding value of the ordinate in a series of terms arranged according to the powers of h . Two cases may occur; the developement may contain only integral powers of h , or it may contain fractional powers. In both cases, if we remember what has been said with respect to the developement of functions, it may be foreseen that the consideration of the values of the differential coefficients of the ordinate, corresponding to the coordinates x' and y' of the point under consideration, may be of great use.

(278.) When the value of the ordinate corresponding to $x' + h$, which we shall designate by y_1 , may be developed according to the integral powers of h , the developement is

$$y_1 = y' + \frac{dy'}{dx'} \cdot h + \frac{d^2y'}{dx'^2} \frac{h^2}{1 \cdot 2} + \dots \dots$$

We have proved that $\frac{dy'}{dx'}$ is the trigonometrical tangent of the angle which the tangent to the curve, at the point whose coordinates are x' and y' , makes with the axis of x ; and that, consequently, the value of the ordinate of the tangent corresponding to the abscissa $x' + h$ is $y' + \frac{dy'}{dx'} \cdot h$. Hence, for the points at which the tangent is parallel to the axis of the curve, we must have $\frac{dy'}{dx'} = 0$.

It does not follow, however, that when this condition is fulfilled the ordinate of the point of contact is always either a maximum or a minimum. If we had, at the same time, $\frac{d^2y'}{dx'^2} = 0$, and not $\frac{d^3y'}{dx'^3} = 0$, or, more generally, if several differential coefficients did vanish, and if the first that did not vanish were of an odd order, it is manifest that there would be neither maximum nor minimum. With respect to the maxima and minima of ordinates of curves, we have to make precisely the same observations as those which have already been made concerning maxima and minima of functions of one variable.

(279.) If we have $\frac{dy'}{dx'} = 0$, and $\frac{d^2y'}{dx'^2} = 0$, then the tangent is still parallel to the axis of x ; but the difference between the ordinate of the curve, and that of the tangent corresponding to the abscissa $x' + h$, being then $\frac{d^3y'}{dx'^3} \frac{h^3}{1 \cdot 2 \cdot 3} + \frac{d^4y'}{dx'^4} \frac{h^4}{1 \cdot 2 \cdot 3 \cdot 4} + \&c.$ it follows that the curve at the point of contact passes from one side of the tangent to the other, since the difference changes sign with h . In that case, therefore, the point $x' y'$ will be a point of *inflexion* or a point of *contrary flexure*. The same reasoning would still apply if we had not $\frac{dy'}{dx'} = 0$,

but simply $\frac{d^2y'}{dx'^2} = 0$, for the difference between the two ordinates of the tangent and curve would still be the same; only the tangent, in that case, would not be parallel to the axis of x . All that has been said would still subsist if the first differential coefficient which does not vanish, instead of being of the third order, was of any odd order.

(280.) Let $F(x, y) = 0$ be the equation of the curve, and let the first differential equation be represented by $N \frac{dy}{dx} + M = 0$. To obtain the value of the first differential coefficient $\frac{dy}{dx}$ corresponding to the point whose

Integral Calculus. coordinates are x', y' , we must substitute in the preceding equation x' for x and y' for y . Let the results of these substitutions in M and N be designated by M' and N' . If $M' = 0$, and N' be equal to a finite quantity, then

$\frac{dy'}{dx'} = 0$, and the tangent to the curve is parallel to the axis of x . Therefore to find points of the curve where this circumstance takes place, it is sufficient to find the systems of values of x and y which satisfy the two equations $F(x, y) = 0$ and $M = 0$, and to choose among them those which do not satisfy the equation $N = 0$: each of these systems will be the coordinates of one of the points required.

Let us next suppose $M' = 0$ and $N' = 0$, then the value of $\frac{dy'}{dx'}$ assumes the form $\frac{0}{0}$. To obtain the true value of this quantity, it will therefore be necessary to proceed to the differential equation of the second order.

Let $N \frac{d^2y}{dx^2} + R \frac{dy}{dx} + Q \frac{dy}{dx} + P = 0$ be this equation, by substituting x' for x and y' for y , and designating by R', Q', P' , the values assumed by R, Q, P , it will become $R' \frac{d^2y'}{dx'^2} + Q' \frac{dy'}{dx'} + P' = 0$, since $N' = 0$ by hypo-

thesis. If the coefficients of this equation be not equal to nothing, it will give generally two values for $\frac{dy'}{dx'}$. These values may be either real and unequal, real and equal, imaginary or infinite. If they be real and unequal, there being two unequal values of the first differential coefficient, corresponding to the same value of x and y , there may be two tangents to the curve at the corresponding point, and therefore two branches may intersect at that point, which, in that case, is a multiple point, and may be called a double point, since there are only two branches intersecting. If the roots be real and equal, there is but one value of the differential coefficient, and, consequently only one tangent. If the roots be imaginary, the developement of y_1 is imaginary, whether h be taken positively or negatively, and therefore the point whose coordinates produce this effect will generally stand alone, insulated, and be, according to the definition, a conjugate point. We shall examine afterwards the case in which the value of the differential coefficient is infinite.

If the values of $R', Q',$ and P' were all equal to nothing, it would be necessary to proceed one step further in the differentiation of the proposed equation, and we should obtain, to find the value of $\frac{dy'}{dx'}$, an equation of the form.

$W' \frac{d^3y'}{dx'^3} + V' \frac{d^2y'}{dx'^2} + T' \frac{dy'}{dx'} + S' = 0$. Then, if the roots of this equation be real and unequal, there may be three tangents at the corresponding point, and three branches of the curve may intersect at it. Therefore the point may be a multiple point or a triple point. If two of the roots be equal, there will be only two distinct values of $\frac{dy'}{dx'}$, and there may be at the point two distinct tangents. If two be imaginary, or if the three roots be equal, there will be only one real value of $\frac{dy'}{dx'}$, and, consequently, one tangent.

If we had also $W' = 0, V' = 0, T' = 0, S' = 0$, then to find the value of $\frac{dy'}{dx'}$ we should use the differential equation of the fourth order, which would give an equation of the fourth degree with respect to $\frac{dy'}{dx'}$. The discussion of the different cases which the roots of this equation might present, would lead to conclusions analogous to the preceding. Generally, it will be necessary to continue the differentiation until some equation is found of which the differential coefficients are not all equal to nothing. Then according to the number and nature of the values of $\frac{dy'}{dx'}$, inferences may be drawn with respect to the existence of a multiple or conjugate point of the curve corresponding to the coordinates x' and y' .

(281.) Let us suppose now that the coordinates x' and y' substituted for x and y in the general value of $\frac{d^2y}{dx^2}$ makes it assume the form $\frac{0}{0}$. Then the value or values, or $\frac{d^2y'}{dx'^2}$ will be obtained like those of $\frac{dy'}{dx'}$ by successive differentiations. If it have several real unequal values, there may be as many for the third term of the developement of y_1 , and therefore as many different branches of the curve may pass through the corresponding point. Since, however, the several values of y_1 would, in that case, agree as to the second term of the developements, they would have all a common tangent. Such a point, therefore, would be a point of osculation. If all the values of $\frac{d^2y'}{dx'^2}$ were found to be imaginary, then the corresponding point would be a conjugate point. Similar conclusions may be applied to the succeeding differential coefficients.

(282.) It is of great importance to add to the conclusions which may be drawn from what precedes that, in some cases, the equation of a curve may be put under such a form that the value of $\frac{dy}{dx}$ derived from it will not assume the form $\frac{0}{0}$ for the values of x and y corresponding to a multiple point, whilst in other circumstances,

Integral
Calculus.

Part III.

although it assumes that form, and the above method gives several values for the differential coefficient, yet the corresponding point is not a multiple point.

To give examples of these cases, let us first consider the curve corresponding to the equation $y = b + (x - a)\sqrt{x - c}$. It is obvious that the point corresponding to the abscissa $x = a$, is a multiple point, if by taking values for $x < \text{or} > a$, the quantity under the radical remains positive, for then there will be on both sides of the point where $x = a$, two distinct branches of the curve passing through that point. However, the value of $\frac{dy}{dx}$ derived from the above equation is $\sqrt{x - c} + \frac{x - a}{2\sqrt{x - c}}$, and does not assume the form $\frac{0}{0}$, but becomes equal to $\sqrt{a - c}$ when x is made equal to a .

On the contrary if we take the equation $ay + bx = xy$, which is that of an hyperbola passing through the origin of the coordinates, and put it under the form $\frac{a}{x} + \frac{b}{y} = 1$, we shall have by differentiation $\frac{dy}{dx} = -\frac{ay^2}{bx^2}$.

This value takes the form $\frac{0}{0}$ for the origin of the coordinates where $x = 0$ and $y = 0$. By differentiating again we find $2bx\frac{dy}{dx} + b x^2 \frac{d^2y}{dx^2} = -2ay\frac{dy}{dx}$. This equation cannot yet give the value of $\frac{dy}{dx}$ corresponding to $x = 0$ and $y = 0$, for by substituting these values for x and y every term of the equation vanishes. A new differentiation leads to the equation $2b\frac{dy}{dx} + 2bx\frac{d^2y}{dx^2} + 2bx\frac{d^2y}{dx^2} + b x^2 \frac{d^3y}{dx^3} = -2ay\frac{d^2y}{dx^2} - 2a\frac{dy^2}{dx^2}$,

which the supposition $x = 0$ and $y = 0$ reduces to $2b\frac{dy}{dx} = -2a\frac{dy^2}{dx^2}$. Hence we might infer that, at the origin, $\frac{dy}{dx}$ has two distinct values, $\frac{dy}{dx} = 0$ and $\frac{dy}{dx} = -\frac{b}{a}$, and, consequently, that the origin is a double point of the curve. However, this conclusion is obviously erroneous, for it is well known that an hyperbola has no multiple points. The right value of $\frac{dy}{dx}$, in this case, is $-\frac{b}{a}$, and is obtained immediately by differentiating the equation of the curve under its first form $ax + by = xy$.

It is also easy to see that the curve represented by the equation $y = b + (x - a)^m \sqrt{x - c}$ has a double point corresponding to $x = a$, when m is an even number, but that that point is simple when m is odd. In neither of these cases the value of $\frac{dy}{dx}$ derived from the above equation becomes $\frac{0}{0}$ for $x = a$. On the contrary, if the equation is first put under the form $(y - b)^m = (x - a)^m (x - c)$, it leads to a value of $\frac{dy}{dx}$ which assumes the form $\frac{0}{0}$ for $x = a$, when m is an even and when it is an odd number. It should be remarked, however, that if by

successive differentiations we try to determine the true value of $\frac{dy}{dx}$, we shall find that the differential equation which gives it has only two real values when m is an even number, and only one if it be odd.

From the preceding observations and examples, we may conclude that to establish with certainty the existence of a singular point indicated by the values assumed at that point, by the differential coefficients of the ordinate, it will always be necessary to examine with attention the values of the ordinates for a portion of the curve very near that point.

(283.) We shall now investigate the figure of a curve at a point whose coordinates render the first or any subsequent differential coefficient infinite.

In that case, x' and y' being still the coordinates of the point, and y_1 the value of the ordinate corresponding to $x' + h$, the developement of y_1 according to the powers of h will contain fractional exponents. Let

$$y_1 = y' + Ah^a + Bh^\beta + Ch^\gamma + \dots \&c.$$

If none of the exponents a, β, γ , &c. be a fraction with an even denominator, the value of y_1 is real whether h be taken positively or negatively. Hence the curve extends on both sides of the ordinate y' . The exponents a, β, γ , being supposed to be arranged in an ascending order, the value of $y_1 - y'$ will depend upon the first term only, for sufficiently small values of h . There are then two cases to examine, first, when the numerator of a is an odd number, and, secondly, when it is even.

If the numerator a be odd, the sign of Ah^a will change with that of h , and consequently at different sides of the point whose coordinates are x' and y' , the curve lies at different sides of a parallel to the axis of x passing through that point. If, in this case, we have $a > 1$, then $\frac{dy'}{dx'} = 0$, and the tangent at that point is parallel to the axis of x . Hence there is an inflexion, (such as in fig. 9,) the first when A is positive, and the second when it is negative. If a be < 1 , then $\frac{dy}{dx}$ is infinite, and the tangent is parallel to the axis of y . Since

the curve extends on both sides of y' , rising above the point of contact on one side, and descending below it on the other, there will be an inflexion such as in fig. 10. the first when A is positive, and the second when it is negative.

Let us next examine the case when the numerator of a is an even number. Then the sign of $A h^a$ does not change with that of h , and $A h^a$ has only one real value, since the denominator of a is necessarily odd. Therefore if a parallel to the axis of x be drawn through the point whose coordinates are x' and y' , the curve lies either above or below this parallel at both sides of the point, according as A is positive or negative. In this case, if a

be > 1 , we have $\frac{d y'}{d x'} = 0$, and, therefore, the parallel to the axis of x is a tangent, and the curve has one or the other of the two positions represented (fig. 11.) If a be < 1 , then $\frac{d y'}{d x'}$ is infinite, and the tangent is parallel to the axis of y . Hence the figure of the curve at the point in question, is one or the other of the two represented (fig. 12.)

If $a = 1$, and if β be a fraction having odd numbers for its numerator and denominator, then $A = \frac{d y'}{d x'}$, and the position of the tangent at the point whose coordinates are x' and y' is determined by the value of A . Moreover, since the sign of the second term $B h^\beta$ changes with the sign of h , and is equal to the first term of the difference between the ordinate of the curve and the ordinate of the tangent corresponding to the abscissa $x + h$, it follows that at different sides of the point of contact, the curve lies at different sides of the tangent, as represented in fig. 2. Hence, in this case, the point is a point of inflexion. In the same case the second differential coefficient $\frac{d^2 y'}{d x'^2} = 0$, if the exponent β be > 2 , and is infinite if β be < 1 . Thus, at a point of inflexion, the

second differential coefficient may be either nothing or infinite. If $a = 1$, and the numerator of β be even, the succeeding exponents not having any even denominator, the point is marked by no peculiarity.

(284.) If amongst the exponents a, β, γ , &c. is found a fraction with an even denominator, then a change in the sign of h changes y_1 from real to imaginary, or *vice versa*. If $+h$ render all the terms of the developement which are affected by such exponents real, and $-h$ imaginary, the curve extends only on the positive side of the ordinate y' , and is excluded from the negative side; and if $-h$ render them real, and $+h$ imaginary, it is just the reverse.

If some of the coefficients A, B, C , &c. are imaginary, and if some of the terms of the series remain imaginary whether h is taken positively or negatively, then the curve is excluded from both sides of the ordinate y' , and the point is a conjugate point.

If $+h$ or $-h$ render all the terms whose exponents have even denominators real, each of such terms will have two real values for every value of h , and, therefore, the number of branches of the curve emerging from the point in question may be double the number of combinations of such powers. The tangent to these branches will be determined by the value of the lowest exponent of h . If it be > 1 , the tangent is parallel to the axis of x , if < 1 , it is parallel to the axis of y , and if $= 1$, its position is determined by the value of the coefficient.

(285.) To illustrate these general principles. Let first $y_1 - y' = A h^{\frac{m}{2n}} + B h^\beta + C h^\gamma$, the first term of the series being the only one in which the exponent is supposed to have an even denominator. In this case $h^{\frac{m}{2n}}$ will be real if h be positive, and imaginary if it be negative. Hence if A be real, for every positive value of h , there are two real values of y_1 , and for any negative value of h , y is imaginary. Then, if $\frac{m}{2n} > 1$, $\frac{d y'}{d x'} = 0$, the tangent is parallel to the axis of x , and there is a cusp of the first kind at the point of contact. If $\frac{m}{2n} < 1$, then $\frac{d y'}{d x'}$ is infinite, the tangent is perpendicular to the axis of x , and is a limit of the curve. These two cases are represented by (fig. 13.) Next, let us suppose A to be an imaginary quantity, such that when $h^{\frac{m}{2n}}$ becomes imaginary by taking h negative, the product $A h^{\frac{m}{2n}}$ remains real; then, on the contrary, the first term of the series will be imaginary for a positive value of h . Consequently the curve will present the same figure as in the preceding case, according as $\frac{m}{2n}$ is greater or less than one, but it will be on the left instead of the right side of the ordinate. If A be an imaginary quantity such that $A h^{\frac{m}{2n}}$ remains imaginary for both $+h$ and $-h$, the point is conjugate.

(286.) Let us suppose, secondly, $y_1 - y' = A h^a + B h^{\frac{m}{2n}} + C h + \&c.$ the second term of the series being the only one in which the denominator is even. The direction of the tangent will be determined as before by the first term $A h^a$. If B is supposed to be a real quantity, as well as all the other coefficients, y_1 will have two real values if h be positive, and will be imaginary if h be negative. Hence there will be two branches of the curve passing through the point whose coordinates are x' and y' and extending only on the positive side of the ordinate

y' . If, on the contrary, B should be an imaginary quantity, such as to make $B h^{\frac{m}{2n}}$ real when h is taken negatively,

and if besides no other coefficient be imaginary, the curve will still have two branches, but both situated on the negative side of the ordinate y' . And, finally, the point will be conjugate, if B being imaginary, $B h^{\frac{m}{2n}}$ remains imaginary for both $+h$ and $-h$.

The two branches of the curve which pass through the point whose coordinates are x' and y' may form, in the case we have just examined, a cusp of the first or of the second kind, according to the value of a . First, if $a = 1$ the tangent common to both branches has an inclined position with respect to both axes, and the difference between the ordinates of the curve and tangent corresponding to the abscissa $x' + h$, beginning with the term $B h^{\frac{m}{2n}}$, shows that one of the branches is above the tangent and the other below, consequently there is a cusp of the first kind, on the right or on the left of y' , according as B is real or imaginary. (Fig. 3.) If a be > 1 , then $\frac{dy'}{dx} = 0$ the tangent is parallel to the axis of x , and the difference between the ordinates of the curve and tangent, corresponding to the abscissa $x' + h$, begins with the term $A h^a$. Therefore both branches will be above or below the tangent according as a is positive or negative, and there is a cusp of the second kind. (Fig. 14.) If B , in the same supposition, were imaginary, the two branches would be on the left of y' , both above the tangent if A were negative, and both below if A were positive, and if a were a fraction with an odd number for numerator; it would be the reverse if the numerator were even. Finally, if a be < 1 , then $\frac{dy'}{dx}$ is infinite, the tangent is parallel to the axis of y , and the two ordinates of the curve corresponding to $x' + h$ are both greater than y' if A is positive, and both less if A be negative, therefore there will be in both cases a cusp of the second kind. (Fig. 15.) If, in the same hypothesis, b be an imaginary quantity, both branches will be situated on the left side of y' , above the point or below the point according as A is positive or negative, and a a fraction whose numerator is an even or an odd number.

(287.) Let us for a last supposition, assume $y_1 - y' = A h^a + B h^b + C h^{\frac{m}{2n}}$, the third term of the series being the only one in which the denominator is even. The position of the tangent will depend on the values of a and A , and from the preceding investigation it obviously results, that the two branches of the curve will be on both sides of the curve represented by the equation $y_1 - y' = A h^a + B h^b$, and of the same side of the tangent, therefore there will be a cusp of the second kind at the point whose coordinates are x' and y' , on the right of the ordinate y' , if C be a real quantity, and on the left if C be an imaginary quantity, which renders $C h^{\frac{m}{2n}}$ real for $-h$, (fig. 16.) If C be an imaginary quantity not satisfying this condition, the point is clearly conjugate.

Generally, if the first and only term of the series, expressing the value of $y_1 - y'$, which has an even number for denominator, be the r^{th} , it is clear that if the coefficient R of that term be not imaginary, the curve will have a cusp of the second kind at the point whose coordinates are x' and y' , the two branches of which will be on the right side of the ordinate y' . There will still be a cusp, but on the other side of y' , if R being imaginary the product $R (-h)^{\frac{m}{2n}}$ be real; and the point will be conjugate if R being imaginary renders $R (\pm h)^{\frac{m}{2n}}$ imaginary.

(288.) The curves represented by the equations $y = x l x$, and $y = \frac{1}{l x}$ have each only one branch passing through the origin, but these branches stop suddenly at that point, where $x = 0$ and $y = 0$, since for a negative value of x , y becomes imaginary. The origin is, therefore, in each of these curves a *stop point*.

It may also be easily seen that the origin is a *shooting point*, in the curves represented by the equations $y = x \tan^{-1} x$, $y = \frac{x}{1 + e^x}$.

(289.) From the preceding investigations we may conclude, that we shall obtain generally an indication of the abscissa, corresponding to a single point of a curve, in determining in what cases the differential coefficients of the ordinate, considered as a function of the abscissa, become infinite, equal to nothing, or assume the form $\frac{0}{0}$. We shall find the species of the point, 1. by examining how many branches of the curve pass through that point, and whether they extend or not on both sides of the point; 2. by determining the position of their tangents; 3. by finding on what side they turn their concavity or convexity.

(290.) We shall now apply these general considerations to a few examples.

Example 1. Let $a y^2 - x^3 - b x^2 = 0$ be the equation of the curve. We easily find $\frac{dy}{dx} = \frac{3x^2 + 2bx}{2ay}$. This value assumes the form $\frac{0}{0}$ at the origin of coordinates where $x = 0$ and $y = 0$. Therefore the origin may be a multiple point. By using the differential equation of the second order, we find $\frac{d^2y}{dx^2} = \pm \sqrt{\frac{b}{a}}$, which indicates a double point at the origin; and by taking the value of y in the equation, we have $y = \pm \sqrt{\frac{x^3 + bx^2}{a}}$, which shows that the curve has in fact two branches passing through that point. If $b = 0$ the two values of $\frac{dy}{dx}$

become equal to each other and equal to nothing. Hence, in that case, the two tangents coincide with each other, and with the axis of x . If then we substitute for x , $0 + h$, or h , we find $y_1 = 0 + h^{\frac{3}{2}}$, from which we conclude that the origin is a cusp of the first kind. If b be negative, the values of $\frac{dy}{dx}$ become imaginary, and the origin is a conjugate point.

Example 2. Let $x^3 - axy - b^2y = 0$, be the equation of the curve. The differential equation is $3x^2dx - aydx - axdy - b^2dy = 0$, and gives $\frac{dy}{dx} = 0$ when $x = 0$ and $y = 0$, therefore the tangent at the origin is parallel to the axis of x . By a new differentiation we get $bxdx^2 - 2adydx - (ax + b^2)d^2y = 0$, and, consequently, at the origin we have also $\frac{d^2y}{dx^2} = 0$. Hence that point may be a point of inflexion or contrary flexure. To ascertain if it be so, we must examine if the value of $\frac{d^3y}{dx^3}$ is also equal to nothing, a new differentiation

gives $bdx^3 - 3ad^2ydx - (ax + b^2)d^3y = 0$, and for $x = 0$ and $y = 0$, $\frac{d^3y}{dx^3} = \frac{b}{b^2}$. Therefore the origin is a point of inflexion.

Example 3. Let $ax^3 + by^3 + c^4 = 0$. We have first $ax^2dx + by^2dy = 0$; and for $x = 0$, and the corresponding ordinate of the curve, $\frac{dy}{dx} = 0$. Hence the tangent at the point whose coordinates are $x = 0$ and $y = -c\sqrt[3]{\frac{c}{b}}$ is parallel to the axis of x . We see, in the same manner, that $\frac{dy}{dx}$ becoming infinite for $y = 0$, and the corresponding abscissa of the curve, the tangent is perpendicular at the axis of x , at the point whose coordinates are $y = 0$ and $x = -c\sqrt[3]{\frac{c}{a}}$. If we determine the values of $\frac{d^2y}{dx^2}$ and $\frac{d^3y}{dx^3}$ corresponding to the first point, we find $\frac{d^2y}{dx^2} = 0$, and $\frac{d^3y}{dx^3} = -\frac{2a}{b}$, therefore it is a point of inflexion. In the same manner, by examining the values of $\frac{d^2x}{dy^2}$ and $\frac{d^3x}{dy^3}$ corresponding to the second point, we shall verify that it is also a point of inflexion.

Example 4. Let $a^3y = x^4$ be the equation of the curve. By differentiation we find $a^3dy = 4x^3dx$, $a^3d^2y = 12x^2dx^2$, $a^3d^3y = 24xdx^3$, $a^3d^4y = 24dx^4$. Hence the values of $\frac{dy}{dx}$, $\frac{d^2y}{dx^2}$, $\frac{d^3y}{dx^3}$ are equal to nothing at the origin, and $\frac{d^4y}{dx^4} = 24$. Hence, the tangent at that point is parallel to the axis of x , but there is no point showing a geometrical inflexion, since the first differential coefficient, which does not become equal to nothing, is of an even order. Such points are sometimes designated under the name of points of double inflexion. It is likewise termed a point of *serpement* or of *undulation*; such points as these are points of inflexion, in an analytical rather than a geometrical sense, since the curve itself presents no visible character of a change in the nature of its curvature.

Example 5. Let there be a series of curves whose equations are

$$y = b + (x - a)^{\frac{2}{3}}, \quad y = b + (x - a)^{\frac{5}{3}}, \quad y = x + (x - a)^{\frac{4}{3}}, \quad y = x + (x - a)^{\frac{7}{3}},$$

and let it be required to find the species of the point corresponding in each to the abscissa $x = a$. In these cases some of the differential coefficients of y become infinite for $x = a$. Therefore the values of the ordinate in each curve, corresponding to $x = a + h$, developed in a series arranged according to the powers of h , will contain fractional powers. If we designate these ordinates by y_1 , we shall have, respectively,

$$y_1 = b + h^{\frac{2}{3}}, \quad y_1 = b + h^{\frac{5}{3}}, \quad y_1 = a + h + h^{\frac{4}{3}}, \quad y_1 = a + h + h^{\frac{7}{3}},$$

and, therefore, according to (284.), we may conclude that there is a point of inflexion in all these curves, corresponding to $x = a$; and also that, in the first, the tangent at the point of inflexion is perpendicular to the axis of x ; in the second, the tangent at the point of inflexion is parallel to the same axis; and in the third and fourth, that the tangent at the point of inflexion is inclined at an angle of 45° to the axis of x .

Example 6. Let $a^3y^2 = x^5$, the differential coefficient $\frac{dy}{dx}$ is equal to nothing at the origin, and, therefore, the tangent at that point is parallel to the axis of x . The third differential coefficient becomes infinite for the coordinates of the same point. The value of y corresponding to $0 + h$ is simply $\frac{h^{\frac{5}{2}}}{a^{\frac{3}{2}}}$, and, consequently, accord-

ing to (284.) the origin presents a cusp of the first kind. In a similar manner it is easy to see that for the point whose coordinates are $x = a$, and $y = b$, there is a cusp of the first kind.

Example 7. Let the equation of the curve be $y - a = (x - b)^{\frac{1}{3}} + (x - b)^{\frac{2}{3}}$. The value $x = b$ renders all the differential coefficients infinite. Hence the tangent at the point corresponding at that abscissa is perpendicular to the axis of x . Let $b + h$ be substituted for x , and we shall have for the corresponding value of y , $y_1 = a + h^{\frac{1}{3}} + h^{\frac{2}{3}}$. Hence (285.) there is a cusp of the second kind, at the point whose coordinates are a and b .

Example 8. Let the equation be $y = a + x + bx^2 + cx^{\frac{5}{2}}$. At the point whose coordinates are $x = 0$ and $y = a$ the value of the first differential coefficient is equal to 1. Therefore the tangent at that point is inclined at an angle of 45° to the axis. For the same values, the third differential coefficient becomes infinite. Substituting then $0 + h$ for x , we find $y_1 = a + h + bh^2 + ch^{\frac{5}{2}}$, and, consequently, (285.) there is at the point under consideration a cusp of the second kind.

Of the Contact of Curves and of Osculating Curves.

(291.) Let $y = f(x)$ and $y = f_1(x)$ be the equations of two curves passing through the same point. Let x' and y' be the coordinates of that point, and y_1, y_2 , the ordinates of the two curves corresponding to the same abscissa $x' + h$. Let us suppose also that none of the differential coefficients of the functions $f(x), f_1(x)$, up to the n^{th} order, become infinite for $x = x'$; and let us represent the values they assume by that substitution, for the first function by A_1, A_2, A_3 , &c. and for the second by B_1, B_2, B_3 , &c. Then we have

$$y_1 = y' + A_1 h + A_2 \frac{h^2}{1.2} + A_3 \frac{h^3}{1.2.3} + \&c., \quad y_2 = y' + B_1 h + B_2 \frac{h^2}{1.2} + B_3 \frac{h^3}{1.2.3} + \&c.$$

These series, expressing the values of y_1 and y_2 , have the same first term, which is the ordinate of the point common to the two curves; but generally the other terms differ from each other. Therefore by subtracting the second equation from the first, we have

$$y_1 - y_2 = (A_1 - B_1) h + (A_2 - B_2) \frac{h^2}{1.2} + (A_3 - B_3) \frac{h^3}{1.2.3} + \&c.$$

If $A_1 = B_1$, the first term of this difference vanishes; if, at the same time, $A_2 = B_2$, the two first terms vanish; if besides $A_3 = B_3$ the three first, and so on. In the first case, that is when the values of the differential coefficients of the ordinates of the two curves, corresponding to the abscissa of the point common to both, are equal to each other, the two curves are said to have a *contact of the first degree, or of the first order*; in the second case, when $A_1 = B_1$, and $A_2 = B_2$, they are said to have a *contact of the second degree, or of the second order*; in the third case, when $A_1 = B_1, A_2 = B_2$, and $A_3 = B_3$, they are said to have a *contact of the third degree or order*; and generally if the values of the coefficients of the n first powers of h in the developement of y_1 , are equal those of the coefficients of the n first powers of h in the developement of y_2 , the two curves are said to have a contact of the n^{th} order.

(292.) An immediate consequence of this definition is, that there is an infinite number of curves, which have, in a given point, and with a given curve, a contact of the n^{th} order. This becomes very obvious if we imagine the origin of coordinates placed at the given point; for, then, h represents the abscissa with respect to the new coordinates, $y_1 - y'$, which we shall call k , the ordinate. Consequently, the equation of the given curve referred to this new line is

$$k_1 = A_1 h + A_2 \frac{h^2}{1.2} + A_3 \frac{h^3}{1.2.3} + \&c. \dots \dots A_n \frac{h^n}{1.2.3 \dots n} + A_{n+1} \frac{h^{n+1}}{1.2.3 \dots n+1} + \&c.$$

and the equation of a curve having with it a contact of the n^{th} order with it, will be, if we designate by k_2 the ordinate

$$k_2 = A_1 h + A_2 \frac{h^2}{1.2} + A_3 \frac{h^3}{1.2.3} + \dots \dots A_n \frac{h^n}{1.2.3 \dots n} + B_{n+1} \frac{h^{n+1}}{1.2 \dots n+1} + \&c.,$$

where all the terms which follow $\frac{A_n h^n}{1.2.3 \dots n}$ remain entirely indeterminate.

(293.) When two curves have a contact of the n^{th} order, no curve, having with them a contact of a less degree, can be drawn through the point of contact, so as to pass between them immediately before or immediately after the point of contact. This theorem is demonstrated in a manner similar to that we have already used for the analogous proposition relative to the tangent.

Let the same notations be employed for the two curves having a contact of the n^{th} order as in number (290.) We have then for the ordinates of these two curves corresponding to the abscissa $x' + h$

$$y_1 = y' + A_1 \frac{h}{1} + A_2 \frac{h^2}{1.2} + A_3 \frac{h^3}{1.2.3} + \dots \dots + \frac{A_n h^n}{1.2.3 \dots n} + \frac{A_{n+1} h^{n+1}}{1.2.3 \dots n+1} + \&c.$$

$$y_2 = y' + A_1 \frac{h}{1} + A_2 \frac{h^2}{1.2} + A_3 \frac{h^3}{1.2.3} + \dots \dots + \frac{A_n h^n}{1.2.3 \dots n} + \frac{B_{n+1} h^{n+1}}{1.2.3 \dots n+1} + \&c.$$

Integral
Calculus.

Part III.

Hence $y_1 - y_2 = (A_{n+1} - B_{n+1}) \frac{h^{n+1}}{1.2.3 \dots n+1} + \&c.$ Let y_3 represent the ordinate of the third curve corresponding to the same abscissa $x' + h$. We shall have

$$y_3 = y' + A_1 \frac{h}{1} + A_2 \frac{h^2}{1.2} + \dots + \frac{A_m h^m}{1.2 \dots m} + \frac{C_{m+1} h^{m+1}}{1.2 \dots m+1} + \&c.$$

m being $< n$, since this third curve is supposed to have with the two others a contact of an order less than n .

We have therefore $y_1 - y_3 = (A_{m+1} - C_{m+1}) \frac{h^{m+1}}{1.2 \dots m+1} + \&c.$ Now, by taking h sufficiently small, we may compare, instead of the differences $y_1 - y_2$ and $y_1 - y_3$, the first terms of the series which express their values; and it is manifest that since m is $< n$, h may always be taken such as to make

$$(A_{n+1} - B_{n+1}) \frac{h^{n+1}}{1.2 \dots n+1} < (A_{m+1} - C_{m+1}) \frac{h^{m+1}}{m+1},$$

if the coefficients $A_{n+1} - B_{n+1}$, and $A_{m+1} - C_{m+1}$ are of the same sign. Hence it follows, that $y_1 - y_2$ is either less than, or of a contrary sign to $y_1 - y_3$, which was to be proved.

(294.) It may also be easily shown, that when two curves have a contact of an even degree, they intersect each other, one of the curves being, on one side of the point of contact above, and on the other side below the other curve. The contrary takes place when the contact is of an odd degree. In the first case, the difference of the series which represent the values of the ordinates of the curves corresponding to an abscissa $x + h$, x being the abscissa of the point of contact, begins with a term containing an odd power of h , consequently it changes sign at the same time as h , and therefore for sufficiently small values of h , if this difference be positive on one side of the point of contact, it will be negative on the other; in the second case, the first term of the difference contains an even power of h , consequently it does not change sign with h , and therefore the difference is positive or negative on both sides of the point of contact.

(295.) We have remarked (292.) that there is an infinite number of curves, which have, in a given point, and with a given curve a contact of the n^{th} order. Hence if the form and position of one of the curves be given, and if the form and position of the second curve may vary with the values of several constants, a, b, c , &c., contained in its equation, it may be proposed to determine these constants by the condition that the second curve shall have with the first a contact of a certain order.

Let $f(x, y) = 0$ be the equation of the first curve, and $\phi(x, y, a, b, c, \&c.) = 0$ that of the second curve. Let x be chosen for the independent variable, and let x, y represent the coordinates of a point taken on the first curve. We shall, generally, be able to determine the values of the constants a, b, c , &c. or of some of them, so that the values of the terms of the series $y, \frac{dy}{dx}, \frac{d^2y}{dx^2}, \frac{d^3y}{dx^3}, \&c.$, corresponding to the abscissa of the point chosen on the first curve, will remain the same in passing from one curve to the other. Then the second curve will pass through the point (x, y) of the first, and will have with it at that point, a contact the order of which will be less by one than the number of the quantities $y, \frac{dy}{dx}, \frac{d^2y}{dx^2}, \frac{d^3y}{dx^3}, \&c.$, which will not have changed their values. Let n be the number of the constants a, b, c , it is clear that they will all be determined if the n first quantities $y, \frac{dy}{dx}, \frac{d^2y}{dx^2}, \&c.$ are made to have the same values in both curves, and that some of them will remain undeter-

minate if fewer than n of the quantities $y, \frac{dy}{dx}, \frac{d^2y}{dx^2}, \&c.$ are made to have the same values in both curves. We

may therefore conclude, that among the systems of values which may be assigned to the constants a, b, c , &c. contained in the equation $\phi(x, y, a, b, c, \&c.) = 0$, there exists one generally for which the curve represented by this equation has with a given curve, at the point the abscissa of which is x , a contact of an order at least equal to the number $n - 1$, and an infinite number of systems of values of these constants, for which the contact between the two curves is of an order inferior to the same number.

To find, among the systems of values of a, b, c , &c., that which determines a contact of an order at least equal to $n - 1$, it is sufficient to combine between them, the formulæ which are obtained by substituting the values of

$$y, \frac{dy}{dx}, \frac{d^2y}{dx^2}, \dots, \frac{d^{n-1}y}{dx^{n-1}}$$

derived from the equation of the given curve in the equation $\phi(x, y, a, b, c, \&c.) = 0$, and its differential equations of an order less than n .

If instead of the abscissa x , any function whatever of x and y were taken for the independent variable, it would be necessary to substitute the values of the quantities $x, y, dx, dy, d^2x, d^2y, \dots, d^{n-1}x, d^{n-1}y$ relative to the given curve, in the equation $\phi(x, y, a, b, c, \&c.) = 0$, and its differential equations of an order inferior to n , considering x and y as independent variables.

(296.) When there are only three constants, a, b, c , in the equation of a curve, it follows clearly from what precedes that an infinite number of systems of values may be assigned for the constants a, b, c , in order that that curve should be tangent to another given curve at a given point. To obtain these systems, it is sufficient to combine the two equations

$$\phi(x, y, a, b, c) = 0, \quad \frac{d\phi(x, y, a, b, c)}{dx} dx + \frac{d\phi(x, y, a, b, c)}{dy} dy = 0,$$

after having substituted the values of x, y, dx, dy , relative to the other given curve. By means of these equations two constants will be found in function of the third, which will remain an arbitrary quantity. The case will be different if it be required that the curve represented by the equation $\phi(x, y, a, b, c) = 0$ should have with the other curve, at the point (x, y) , a contact of an order at least equal to two, or in other words, if it be required that the point (x, y) should become for both curves a point of osculation. Then the three constants a, b, c will be determined by the system of the three equations

$$\begin{aligned} \phi(x, y, a, b, c) = 0, \quad \frac{d\phi(x, y, a, b, c)}{dx} dx + \frac{d\phi(x, y, a, b, c)}{dy} dy = 0, \\ \frac{d^2\phi(x, y, a, b, c)}{dx^2} dx^2 + \frac{2d^2\phi(x, y, a, b, c)}{dx dy} dx dy + \frac{d^2\phi(x, y, a, b, c)}{dy^2} dy^2 \\ + \frac{d\phi(x, y, a, b, c)}{dx} d^2x + \frac{d\phi(x, y, a, b, c)}{dy} d^2y = 0. \end{aligned}$$

If the equation $\phi(x, y, a, b, c)$ belongs to a circle, the three constants a, b, c are the coordinates of the centre and the radius; if we represent them respectively by $x', y',$ and ρ , the equation of the circle is $(x - x')^2 + (y - y')^2 = \rho^2$, and we have to determine the three quantities x', y' and ρ , the three equations

$$(x - x')^2 + (y - y')^2 = \rho^2, \quad (x - x') dx + (y - y') dy = 0, \quad (x - x') d^2x + (y - y') d^2y + dx^2 + dy^2 = 0.$$

The two first equations would determine the relation which exists between the abscissæ and ordinates of the centres of all the circles which touch the given curve at a given point. It is obvious, from the second equation, that all those centres are placed on the normal to the given curve, at the given point. We shall soon resume this question, or the determination of the coordinates of the centre and radius of the circle which has with a given curve a contact of the second order at a given point. But before leaving these general notions, we shall propose as an example to determine the n constants in the equation $y = a + bx + cx^2 + \dots + px^{n-2} + qx^{n-1}$, by the condition that the parabolic curve which it represents shall have with a given curve, at a given point, a contact of an order equal or superior to $n - 1$.

If we take x for the independent variable, we shall have by differentiating $n - 1$ times,

$$\begin{aligned} y &= a + bx + cx^2 + \dots + px^{n-2} + qx^{n-1}, \\ \frac{dy}{dx} &= b + 2cx + \dots + (n-2)px^{n-3} + (n-1)qx^{n-2}, \\ &\text{&c.} \qquad \qquad \qquad \text{&c.} \\ \frac{d^{n-2}y}{dx^{n-2}} &= 1.2.3 \dots (n-2)p + 2.3.4 \dots (n-1)qx, \\ \frac{d^{n-1}y}{dx^{n-1}} &= 1.2.3 \dots (n-1)q. \end{aligned}$$

These n equations, after having substituted for $x, y, \frac{dy}{dx}, \dots, \frac{d^{n-2}y}{dx^{n-2}}, \frac{d^{n-1}y}{dx^{n-1}}$, their values relative to the given curve and to the given point, will be sufficient to determine the values of the n constants $a, b, c, \dots, p, q$.

Let x_1, y_1 , be the coordinates of a point of the parabolic curve, which does not coincide with the given point (x, y) , this curve will then be represented by the equation resulting from the elimination of the n constants between the n above equations, and the equation

$$y_1 = a + bx_1 + cx_1^2 + \dots + px_1^{n-2} + qx_1^{n-1}.$$

But the right side of this equation may be developed according to the powers of $x_1 - x$, in observing that for any value whatever of the integer m we have

$$x_1^m = \{x + (x_1 - x)\}^m = x^m + \frac{m}{1} x^{m-1} (x_1 - x) + \frac{m(m-1)}{1.2} x^{m-2} (x_1 - x)^2 + \dots + (x_1 - x)^m.$$

Hence we shall find

$$\begin{aligned} y_1 &= a + bx + cx^2 + \dots + px^{n-2} + qx^{n-1}, \\ &+ \frac{b + 2cx + \dots + (n-2)px^{n-3} + (n-1)qx^{n-2}}{1} (x_1 - x), \\ &+ \text{&c.} \\ &+ \frac{1.2.3 \dots (n-2)p + 2.3.4 \dots (n-1)qx}{1.2.3 \dots (n-2)} (x_1 - x)^2, \\ &+ \frac{1.2.3 \dots (n-1)q}{1.2.3 \dots (n-1)} (x_1 - x)^{n-1}. \end{aligned}$$

In this development we see that the coefficients of the successive powers of $(x_1 - x)$ are precisely the values

Part III.
Integral
Calculus.

Part III.

we have found above for $y, \frac{dy}{dx}, \frac{d^2y}{dx^2}, \dots, \frac{d^{n-2}y}{dx^{n-2}}, \frac{d^{n-1}y}{dx^{n-1}}$, therefore by substituting, we shall find for the required equation of the parabolic curve

$$y_1 = y + \frac{dy}{dx} \frac{(x_1 - x)}{1} + \frac{d^2y}{dx^2} \frac{(x_1 - x)^2}{1.2} + \dots + \frac{d^{n-2}y}{dx^{n-2}} \frac{(x_1 - x)^{n-2}}{1.2.3 \dots (n-2)} + \frac{d^{n-1}y}{dx^{n-1}} \frac{(x_1 - x)^{n-1}}{1.2.3 \dots (n-1)},$$

when $x, y, \frac{dy}{dx}, \frac{d^2y}{dx^2}, \dots, \frac{d^{n-2}y}{dx^{n-2}}, \frac{d^{n-1}y}{dx^{n-1}}$ are the abscissa and ordinate of the given point on the given curve, and the differential coefficients of the ordinate corresponding to the given point derived from the equation of the given curve.

This simple and elegant formula might also be obtained very easily by first putting the equation of the parabolic curve under the form

$$y_1 - y = B(x_1 - x) + C(x_1 - x)^2 + \dots + P(x_1 - x)^{n-2} + Q(x_1 - x)^{n-1},$$

in which it is expressed that the curve passes through the point (x, y) , and then determining the constants $B, C, \dots, P, Q$ by the condition that the $(n-1)$ first differential coefficients of the ordinate derived from this

equation, and corresponding to $x_1 = x$ are equal to $\frac{dy}{dx}, \frac{d^2y}{dx^2}, \dots, \frac{d^{n-2}y}{dx^{n-2}}, \frac{d^{n-1}y}{dx^{n-1}}$. It is in this manner that the

equation of the tangent, or the parabolic line of the first degree having with a given curve in a given point a contact of the first order, has been found.

(297.) It will be necessary before we proceed to another important application of the theory of contact of curves, to determine the differential of an arc of a curve, the arc being considered as a function of the abscissa.

We have already had occasion to remark, that there are functions of one or more variables, which are such that although we cannot express the relation which exists between the function and the variables, either explicitly, or by means of equations, yet we can find the differential of the function. The arc considered as a function of the abscissa is an example of the case just mentioned.

Let us consider a plain curve represented by an equation between two rectangular coordinates x, y , and let s be the arc of this curve contained between a fixed point and the point (x, y) . If through this last point we draw a

tangent to the curve, the tangent of the acute angle which this tangent makes with the axis of x , is equal to $\frac{dy}{dx}$,

and therefore the secant of the same angle is equal to $\sqrt{1 + \frac{dy^2}{dx^2}}$. If, moreover, we draw an ordinate corresponding to the abscissa $x + h$, the portions of the curve and tangent, contained between the point (x, y) and

this ordinate may be represented the first by l , and the other is clearly equal to $h \sqrt{1 + \frac{dy^2}{dx^2}}$.

Let $y = f(x)$ be the equation of the curve under consideration, then we shall have $y + \kappa = f(x) + (f'(x + \theta h) - f'(x))h$, θ being a quantity less than one, and $f'(x)$ being the differential coefficient of $f(x)$. Hence we have $\kappa = \{f'(x + \theta h) - f'(x)\}h$.

Let us suppose now that the point whose coordinates are $x + h$ and $y + \kappa$, and the point (x, y) are so near each other that the two functions y and $\frac{dy}{dx}$, or $f(x)$ and $f'(x)$ are continuous functions in passing from one point

to the other, and that the second $\frac{dy}{dx} = f'(x)$ is constantly increasing or decreasing in all the values between x

and $x + h$. Then in the curvilinear triangle formed by the curve, the tangent, and the ordinate corresponding to the abscissa $x + h$, the second and third sides will be portions of straight lines, and the first a convex line. Therefore each side of this triangle will be inferior to the sum of the other two, and the difference between the two first sides will have a numerical value inferior to the third. Therefore the numerical values of the quantities

l and $h \sqrt{1 + \frac{dy^2}{dx^2}}$ will have a numerical value inferior to $(f'(x + \theta h) - f'(x))h$, and, in dividing these

three by h , we must conclude that the difference $\pm \frac{l}{h} - \sqrt{1 + \frac{dy^2}{dx^2}}$ will have a numerical value less than

$f'(x + \theta h) - f'(x)$. If we suppose that h converges towards zero, the expression $f'(x + \theta h) - f'(x)$ will

converge towards the same limit; but then $\frac{l}{h} = \frac{ds}{dx}$, therefore $\pm \frac{ds}{dx} - \sqrt{1 + \frac{dy^2}{dx^2}} = 0$, or

$ds = \pm \sqrt{1 + \frac{dy^2}{dx^2}} \cdot dx = \pm \sqrt{dx^2 + dy^2}$. The sign $+$ in this formula must be taken when the arc

increases at the same time as the abscissa, and the sign $-$ in the contrary case.

Hence if we designate by a the acute angle which the tangent to the curve at the point (x, y) makes with the axis of x , we shall have

$$\cos a = \pm \frac{dx}{ds}, \sin a = \pm \frac{dy}{ds}, \sec a = \pm \frac{ds}{dx}, \operatorname{cosec} a = \pm \frac{ds}{dy}.$$

Integral
Calculus.and the lengths of the normal and tangent between the point of contact and the axis of x will be respectively Part III.

$$\pm y \frac{ds}{dx}, \pm y \frac{ds}{dy}.$$

The chord of the arc we have above designated by l is the distance of the points (x, y) and $(x + h, y + \kappa)$, hence it is equal to $\sqrt{(h^2 + \kappa^2)}$. Consequently the ratio of the arc to its chord is $\frac{\pm l}{\sqrt{(l^2 + h^2)}}$, but, at the limit,

$$l = ds, \text{ and } \sqrt{(l^2 + h^2)} = \sqrt{(dx^2 + dy^2)}, \text{ therefore at the limit } \frac{\pm l}{\sqrt{(l^2 + h^2)}} = \frac{\pm ds}{\sqrt{(dx^2 + dy^2)}} = 1. \text{ Therefore}$$

when the arc of a plane curve becomes infinitely small the ratio of the arc to the curve becomes equal to one, or in other words, the limit of the ratio between the arc and the chord of a plane curve is equal to one.

Let a and b represent the angles which the chord joining the points (x, y) , $(x + h, y + \kappa)$ makes with the axis of x and y , each of these angles being comprised between 0° and 180° . Let also α and β be the limits towards which the angles a and b converged when the point $(x + h, y + \kappa)$ approaches indefinitely to the point (x, y) , that is to say, in other words, the angles formed by the tangent produced in the same direction as the chord with the

semi-axis of positive coordinates. We have $\cos a = \frac{h}{\sqrt{(h^2 + \kappa^2)}}$, $\cos b = \frac{\kappa}{\sqrt{(h^2 + \kappa^2)}}$, and at the limits we shall find

$$\cos \alpha = \frac{dx}{\sqrt{(dx^2 + dy^2)}}, \cos \beta = \frac{dy}{\sqrt{(dx^2 + dy^2)}}. \text{ But } \sqrt{(dx^2 + dy^2)} = \pm ds, \text{ therefore we shall have either}$$

$$\cos \alpha = \frac{dx}{ds}, \text{ and } \cos \beta = \frac{dy}{ds}, \text{ or } \cos \alpha = -\frac{dx}{ds}, \cos \beta = -\frac{dy}{ds}. \text{ The two first values are to be used when the}$$

tangent has been produced in the same direction as the arc s , and the two last when it has been produced in a contrary direction. This is obvious if we observe that the ratio $\frac{dx}{ds}$ being the limit of $\frac{h}{\kappa}$ will be positive when the

arc s increases at the same time as x , or, in other words, when the tangent, produced in the same direction as the arc, forms with the semi-axis of the positive abscissæ an acute angle, and consequently an angle the cosine of which is positive. If this angle become obtuse, its cosine and the ratio $\frac{dx}{ds}$ will become at the same time nega-

tive. Therefore the formulæ $\cos \alpha = \frac{dx}{ds}$, $\cos \beta = \frac{dy}{ds}$ must be preferred to the formulæ $\cos \alpha = -\frac{dx}{ds}$,

$\cos \beta = -\frac{dy}{ds}$, when the tangent is produced in the same direction as the arc.

(298.) Let us consider now two plane curves. Let x, y be the coordinates of the first, and s the arc of this curve comprised between a fixed point and the point (x, y) . Let x_1, y_1 and s_1 be the analogous quantities for the second curve. We shall have $ds^2 = dx^2 + dy^2$, $ds_1^2 = dx_1^2 + dy_1^2$. Let the tangents drawn to the first curve through the point (x, y) , and to the second curve through the point (x_1, y_1) be produced in the same direction as the arcs s , and s_1 , then they will form angles with the semi-axis of positive coordinates the cosines of which will be for the first tangent equal to $\frac{dx}{ds}$, $\frac{dy}{ds}$, and, for the second tangent, $\frac{dx_1}{ds_1}$, $\frac{dy_1}{ds_1}$. Hence

$$\text{if we call } \delta \text{ the angle of the two tangents, we shall have } \cos \delta = \frac{dx}{ds} \cdot \frac{dx_1}{ds_1} + \frac{dy}{ds} \cdot \frac{dy_1}{ds_1} = \frac{dx dx_1 + dy dy_1}{ds ds_1}.$$

$$\text{The two tangents will be parallel, when we shall have } \frac{dx_1}{ds_1} = \frac{dx}{ds}, \frac{dy_1}{ds_1} = \frac{dy}{ds}, \text{ or } \frac{dx_1}{ds_1} = -\frac{dx}{ds}, \frac{dy_1}{ds_1} = -\frac{dy}{ds}.$$

It is obvious that these two cases are included in the formula $\frac{dx_1}{dx} = \frac{dy_1}{dy}$, from which we derive

$$\frac{dx_1}{dx} = \frac{dy_1}{dy} = \pm \frac{\sqrt{(dx_1^2 + dy_1^2)}}{\sqrt{(dx^2 + dy^2)}} = \pm \frac{ds_1}{ds}.$$

If in the value we have just found for $\cos \delta$ we substitute for ds and ds_1 their values, we shall find

$$\cos \delta = \pm \frac{dx dx_1 + dy dy_1}{\sqrt{(dx^2 + dy^2)} \sqrt{(dx_1^2 + dy_1^2)}}. \text{ When in this last equation the sign of the right side is not deter-}$$

mined, it gives two values of δ which represent the acute and the obtuse angles formed by the two tangents produced on both sides of the points (x, y) , (x_1, y_1) .

When two curves meet, they are supposed to form the same angle as the tangents drawn through their common point. Then $x_1 = x$ and $y_1 = y$, and the angles formed by the two curves have for measures the values of δ we have found above.

Two curves are said to be normal to each other when they meet at right angles, that is to say, when their tangents drawn through their common point are perpendicular to each other, that is when the equation

$$1 + \frac{dy_1}{dx_1} \frac{dy}{dx} = 0 \text{ is verified for their point of intersection.}$$

Integral
Calculus.

Part III.

(299.) The following theorem may now be easily demonstrated. Two plane curves having a common point, and a common tangent at that point, if, on these curves, produced in the same direction, equal and very small lengths be taken from the point of contact, the straight line joining the extremities of these lengths will be very nearly parallel to the normal common to both curves.

Let us suppose that the equal lengths, which are taken on the first and second curve from the point of contact, have respectively for their extremities the points (x, y) and (x_1, y_1) . Let, moreover, s and s_1 be the lengths of the arcs of these two curves contained between two fixed points arbitrarily chosen on them, and the points (x, y) , (x_1, y_1) when the coordinates x, y, x_1, y_1 , will vary simultaneously, the difference $s_1 - s$ will remain constant, and, consequently, we shall have $ds_1 = ds$. Let α, β be the angles which the tangent common to both curves, and produced in the same direction as the arcs s and s_1 , forms with the semiaxis of the positive coordinates; let l be the distance of the two points (x, y) , (x_1, y_1) , and λ and μ the angles which the line joining these two points forms with the semiaxis of positive coordinates. We shall have

$$\cos \alpha = \frac{dx}{ds} = \frac{dx_1}{ds_1}, \quad \cos \beta = \frac{dy}{ds} = \frac{dy_1}{ds_1}, \quad l = \sqrt{(x - x_1)^2 + (y - y_1)^2}, \quad \cos \lambda = \frac{x - x_1}{l},$$

$$\cos \mu = \frac{y - y_1}{l}, \text{ and since } ds = ds_1, \quad dx^2 + dy^2 = dx_1^2 + dy_1^2, \text{ or } (dx + dx_1)(dx - dx_1)$$

$$+ (dy + dy_1)(dy - dy_1) = 0.$$

But the values of $\cos \alpha$ and $\cos \beta$ give $\frac{dx + dx_1}{\cos \alpha} = \frac{dy + dy_1}{\cos \beta} = 2 ds$; moreover, since for a value of x ,

differing but very little from a particular value of that variable which renders two given functions of x equal to nothing, the ratio between these functions differs very little from the ratios between their differential coefficients, and, consequently, from the ratio between their differentials, even though these differentials would become nothing for the same particular value of x , we see that the quantities $\cos \lambda, \cos \mu$, may be determined approximatively by the

following formulæ, $\cos \lambda = \frac{dx - dx_1}{dl}, \quad \cos \mu = \frac{dy - dy_1}{dl}$. Hence we shall have very nearly $\frac{dx - dx_1}{\cos \lambda} =$

$\frac{dy - dy_1}{\cos \mu} = dl$. The nearer the points (x, y) , (x_1, y_1) , are to the point of contact of the two curves, the more

exact is the last formula. If now we substitute in the formula $(dx + dx_1)(dx - dx_1) + (dy + dy_1)(dy - dy_1) = 0$, for the quantities $dx + dx_1$, and $dy + dy_1$, the quantities $\cos \alpha, \cos \beta$, which are proportional to them, and for the quantities $dx - dx_1, dy - dy_1$, the quantities $\cos \lambda$ and $\cos \mu$ which are proportional to them, we shall find $\cos \alpha \cos \lambda + \cos \beta \cos \mu = 0$. Therefore the straight line drawn through the points (x, y) , (x_1, y_1) will be very nearly perpendicular to the tangent, that is to say parallel to the normal.

(300.) Let r be the radius of a circle which touches a straight line in a given point. If we increase the length of r , the portion of the circumference about the point of contact, will differ less and less from a straight line, and will sensibly, within a small space about the point of contact, coincide with the straight tangent, when $\frac{1}{r}$ will nearly be equal to nothing. On the contrary the curvature of the circumference will increase more and more, when the radius decreases, or when the quantity $\frac{1}{r}$ increases. Hence it is natural to take the quantity $\frac{1}{r}$ for the

measure of what may be called the curvature of the circle. Let x, y , represent the coordinates of any point of the circumference, θ the angle which the tangent at that point makes with the axis of x , s the length of the arc between that point and a fixed point on the circumference, and let h, κ, t, l , be the respective increments of these variables when we pass from the point (x, y) to a point sufficiently near it that we may suppose the angle θ to have constantly increased or decreased in the interval. The length of the arc between the two last points is precisely $\pm l$, and the angle of the two radii, which are drawn to the extremities of the arc, is equal to the angle $\pm t$ formed by the two tangents. This understood, we shall have obviously $\pm l = \pm r t$, and, consequently, we shall have

for the curvature of the circle $\frac{1}{r} = \pm \frac{t}{l}$.

Let us conceive now that $x, y, x + h, y + \kappa$, are the two coordinates of two points not situated on the circumference of a circle, but on any curve whatever, and moreover, let them be near enough to each other that the angle θ may still be supposed to increase or decrease in a continuous manner in going from one point to the other. The ratio $\pm \frac{t}{l}$ will vary in general with the arc $\pm l$, and will be what may be called the *mean curvature* of that arc. If the

quantities h and κ are supposed to decrease indefinitely, or the point $(x + h, y + \kappa)$ to approach indefinitely to the point (x, y) , the quantities $\pm l, \pm t$, will converge towards the limit zero. But the limit towards which will,

at the same time, converge their ratio, is $\frac{d\theta}{ds}$, and in general will be a finite quantity, which we shall call the

curvature of the curve at the point (x, y) .

The angle $\pm t$ formed by the two tangents drawn at the extremities of the arc $\pm l$ is called generally the angle of contingence.

When the arc $\pm l$ is very small, the chord joining its extremities is very nearly perpendicular to the two normals drawn to the curve through the points (x, y) , $(x + h, y + \kappa)$; and the distance of the point (x, y) to the point

Integral
Calculus.

where the two normals meet is nearly equal to the radius of a circle, which would have the same curvature as the curve. For, let r be this distance, and s the limit towards which it converges. In the triangle formed by the two normals and the chord of the arc $\pm l$, the angle opposed to this chord will obviously be equal to the angle of contingence $\pm t$, whilst the angle opposed to the side r will differ very little from a right angle. Hence, if ϵ

Part III.

represent an infinitely small number, we shall have $\frac{\sin\left(\frac{\pi}{2} \pm \epsilon\right)}{r} = \frac{\sin(\pm t)}{\sqrt{(h^2 + k^2)}}$. And, consequently, at the limit

$\frac{1}{\rho} = \pm \frac{d\theta}{\sqrt{(dx^2 + dy^2)}}$, or $\frac{1}{\rho} = \pm \frac{d\theta}{ds}$. From this last formula it clearly results that ρ expresses the radius of a

circle the curvature of which is equal to $\pm \frac{d\theta}{ds}$. This radius is called the *radius of curvature* of the curve at the

point (x, y) , and if its length be taken from the point (x, y) , on the normal at that point, it determines on that normal the point which is called the *centre of curvature*, which may also be considered as the point where the two normals, drawn at the extremities of the infinitely small arc ds , meet. The circumference which has for its centre the centre of curvature, and for radius the radius of curvature, is called the *circle of curvature*, or the *osculating circle* at the point (x, y) .

(301.) The curvature, and the radius of curvature of a curve, may be expressed under various forms which are important to know, and which we shall now proceed to explain.

If we take x for the independent variable we shall have

$$\tan \theta = \pm \frac{dy}{dx}, \quad \theta = \pm \tan^{-1} \frac{dy}{dx}, \quad d\theta = \pm \frac{\frac{d^2y}{dx^2}}{1 + \frac{dy^2}{dx^2}} \cdot dx, \quad ds = \pm \sqrt{1 + \frac{dy^2}{dx^2}} \cdot dx,$$

and, consequently,

$$\frac{1}{\rho} = \pm \frac{\frac{d^2y}{dx^2}}{\left(1 + \frac{dy^2}{dx^2}\right)^{\frac{3}{2}}} = \pm \frac{d^2y}{dx^2} \cdot \frac{1}{\sec^3 \theta}.$$

The last formula shows immediately that the curvature becomes nothing, and the radius of curvature infinite, whenever $\frac{d^2y}{dx^2} = 0$. Then the osculating circle is a straight line and coincides with the tangent. This takes place, for instance, at the point of contrary flexure of the curve represented by the equation $y = x^3$, and generally for all the points of contrary flexure in the immediate vicinity of which the functions $\frac{dy}{dx}$, $\frac{d^2y}{dx^2}$ remain continuous. If for a certain point the value $\frac{d^2y}{dx^2}$ be infinite, without the tangent being perpendicular to the axis of x , the curvature would be infinite, and the radius of curvature would vanish. Lastly, if the quantities $\frac{dy}{dx}$, $\frac{d^2y}{dx^2}$ were both to be-

come infinite, the fraction $\pm \frac{\frac{d^2y}{dx^2}}{\left(1 + \frac{dy^2}{dx^2}\right)^{\frac{3}{2}}}$ would assume an undeterminate form, but its true value might be

found by means of the rules previously given. Sometimes, whilst the abscissa x varies in a continuous manner, the value of the radius of curvature changes suddenly. This circumstance may occur not only for the points of curves which have been called *shooting or salient points*, when the function $\frac{dy}{dx}$ becomes discontinuous by changing suddenly of value, but also when this function remaining continuous, the value of $\frac{d^2y}{dx^2}$ is discontinuous. This takes place, for instance, in each of the curves represented by the equations $y = x\left(1 + \tan^{-1} \frac{1}{x}\right)$, $y = x^2\left(1 + \tan^{-1} \frac{1}{x}\right)$, at the point which coincides with the origin of the coordinates, which point is at the same time a shooting or salient point of the first curve, and a point of contact of the second curve with the axis of x . The radius of

curvature of the first curve is equal to $\pm \frac{\left\{\left(1 + \tan^{-1} \frac{1}{x} - \frac{x}{1+x^2}\right)^2 + 1\right\}^{\frac{3}{2}}}{2} (1+x^2)$; when the sign of x is

changed it becomes $\pm \frac{\left\{ \left(1 - \tan^{-1} \frac{1}{x} + \frac{x}{1+x^2} \right)^2 + 1 \right\}^{\frac{3}{2}} (1+x^2)}{2}$, and, consequently, when x vanishes previous

to changing its sign, the radius of curvature passes from the value $\frac{1}{2} \left\{ \left(\frac{\pi}{2} - 1 \right)^2 + 1 \right\}^{\frac{3}{2}}$ to the value $\frac{1}{2} \left\{ \left(\frac{\pi}{2} + 1 \right)^2 + 1 \right\}^{\frac{3}{2}}$. In the same circumstances the radius of curvature of the second curve passes from the value $\frac{1}{\pi - 2}$ to $\frac{1}{\pi + 2}$.

If in the formula $\frac{1}{\rho} = \pm \frac{d^2 y}{d x^2} \cdot \frac{1}{\sec^3 \theta}$, we substitute for $\sec \theta$ its value $\frac{y}{N}$, N being the length of the normal, we find $\rho = \pm \frac{N^3}{y^3} + \frac{1}{\frac{d^2 y}{d x^2}}$. By means of this expression the radii of curvature of several curves are very easily found.

We shall take for first example the curve represented by the equation $y^2 = 2 p x + q x^2$, where p is a positive quantity. This curve is an ellipse, a parabola, or an hyperbola, according as the quantity q is negative, nothing, or positive. Moreover, it is easy to see, 1. that the axis of x coincides with one of the axes of the curve, and the origin with one extremity of this axis; 2. that in the case where the constant q is greater than the quantity -1 , p represents the parameter, that is to say the ordinate drawn through one of the foci of the curve. Now if we differentiate the equation of the curve, we find $y \frac{d y}{d x} = p + q x$, and, consequently, $y^2 \frac{d^2 y}{d x^2} = p^2 + 2 p q x + q^2 x^2 = p^2 + q y^2$, $\frac{d^2 y}{d x^2} = \frac{p^2}{y^3} + q$, and then if we differentiate again, $\frac{d^3 y}{d x^3} = -\frac{p^2}{y^4}$. Thus we shall have $\rho = \frac{N^3}{p^2}$, and, consequently, in the curve represented by the equation $y^2 = 2 p x + q x^2$, the radius of curvature is equal to the cube of the normal, divided by the square of the length p . If we substitute for N its value $N = \sqrt{y^2 + y \frac{d y}{d x}} = \{ p^2 + (1 + q) y^2 \}^{\frac{1}{2}}$, we shall find $\rho = \frac{\{ p^2 + (1 + q) y^2 \}^{\frac{3}{2}}}{p^2} = \frac{\{ p^2 + (1 + q) (2 p x + q x^2) \}^{\frac{3}{2}}}{p^2}$. And lastly, when $q = 0$, or when the curve is a parabola, represented by the equation $y^2 = 2 p x$, we shall have simply $\rho = \frac{(p^2 + y^2)^{\frac{3}{2}}}{p^2} = p \left(1 + \frac{2 x}{p} \right)^{\frac{3}{2}}$. Both this last value, and the general value, become equal to p when $x = 0$,

in which case the value of y , or the ordinate of the curve, is also equal to nothing. Hence we may conclude that in the parabola, the ellipse, and the hyperbola, the radius of curvature corresponding to the summit, at one of the extremities of the greater axis, or of the real axis, is equal to the parameter.

Let us consider for a second example the ellipse or hyperbola, the axis of which is a and b , and the equation of which is $\frac{x^2}{a^2} \pm \frac{y^2}{b^2} = \pm 1$. By two successive differentiations we shall find $\frac{x}{a^2} \pm \frac{y}{b^2} \frac{d y}{d x} = 0$, $\frac{d y}{d x} = \pm \frac{b^2}{a^2} \left(\frac{b^2}{y^2} \mp 1 \right)$, $\frac{d^2 y}{d x^2} = \mp \frac{b^4}{a^2 y^3}$, and $y^2 \cdot \frac{d^2 y}{d x^2} = \mp \frac{b^4}{a^2}$. Hence $\rho = \frac{N^3}{\left(\frac{b^2}{a^2} \right)^2}$, or by substituting for N its value

$$\rho = \frac{\left(\frac{b^2}{a^2} x^2 \pm a^2 \mp x^2 \right)^{\frac{3}{2}}}{a b} = \frac{\left(\frac{b^2}{a^2} x^2 + \frac{a^2}{b^2} y^2 \right)^{\frac{3}{2}}}{a b}.$$

If we consider in particular the ellipse $\frac{x^2}{a^2} + \frac{y^2}{b^2} = 1$, we shall find for the radius of curvature at the extremity of the axis $2 a$ $\rho = \frac{b^2}{a}$, and for the radius of curvature at the extremity of the axis $2 b$, $\rho = \frac{a^2}{b}$. Thus if $2 a$ represent the greater axis, $\frac{b^2}{a}$ will be the parameter designated in the preceding example by the constant p .

(302.) We shall take for the third example the cycloid. Let us suppose that from the origin of the coordinates we take on the axis of y , and in the direction of the positive ordinates, a length equal to r . Let us describe from the extremity of this length as a centre with a radius equal to r a circumference of a circle, and let this circumference be supposed to roll along the axis of x without ceasing to be tangent to it. The point of the circumference which at the first instant coincided with the origin of coordinates will describe the curve which is called *cycloid*. The curves described by a point within or without the generating circle, and moving with it, are called *trochoidal curves*.

Integral
Calculus.

Part III.

The equation of the cycloid may easily be found by the following considerations. Whilst the circle rolls on the axis of x , the centre moves parallel to the same axis, and the radius which in the first instant passed through the origin of coordinates, will turn round the centre in describing an angle which will continually increase. Let us designate by ω this angle; by x_1, y_1 , the coordinates of the centre; and by x, y the coordinates of the extremity of the moving radius, which will also be the coordinates of a point of the cycloid. The arc of circle between the extremity just mentioned, and the point where the circle touches the axis of x , will have obviously for measure the product $r\omega$; and since all the parts of this arc will have been applied successively one after the other, on parts of the axis of x , contained between the origin and the point of contact, equal to them in length, at any instant the distance of the point of contact to the origin of coordinates, or, which is the same thing, the abscissa of the centre of the circle, will have a length equal to $r\omega$. Hence, if we suppose that the circle moves in the direction of the positive x , we shall have $x_1 = r\omega, y_1 = r$. Moreover, it is obvious that the projections of the moving radius on the axis of x and y may be represented either by $x - x_1, y - y_1$, or by $-r \sin \omega, -r \cos \omega$. Therefore we shall have $x - x_1 = -r \sin \omega, y - y_1 = -r \cos \omega$, or $x = x_1 - r \sin \omega, y = y_1 - r \cos \omega$, and by substituting for x_1 and y_1 their values, we shall find $x = r(\omega - \sin \omega), y = r(1 - \cos \omega)$. It will be sufficient to extend these two last formulæ to the case where ω becomes negative, to obtain the coordinates x, y of the points of the cycloid situated on the side of the negative x , that is to say, the coordinates of the points with which coincides successively the extremity of the moving radius when the circle moves on that side. If now we take the value of ω in the equation $y = r(1 - \cos \omega)$ to substitute it in the value of x , we shall find, in supposing first the angle ω between

the limits 0 and π , $x = r \cos^{-1} \left(\frac{r-y}{r} \right) - \sqrt{(2ry - y^2)}$, and secondly, supposing the angle ω contained between the limits $\pm n\pi, \pm n\pi + \pi$, n being an integer, $x = r \cos^{-1} \left(\frac{r-y}{r} \right) \pm n\pi - \cos n\pi \sqrt{(2ry - y^2)}$,

which two formulæ may be replaced by $x = r \cos^{-1} \left(\frac{r-y}{r} \right) \pm \sqrt{(2ry - y^2)}$, where the radical must be taken with the sign $+$ or the sign $-$ according as the difference between the value taken for $\cos^{-1} \left(\frac{r-y}{r} \right)$, and the smallest value of that quantity, divided by π , gives an even or an odd number for quotient.

The basis of the cycloid is the straight line on which the generating circle is made to roll, and which has been taken for the axis of x .

It is easy to see by means of these equations, that the cycloid is composed of an infinite number of branches all equal to each other, and such that the extreme points situated on the axis of x answer to the abscissæ $x=0, x=\pm 2\pi r, x=\pm 4\pi r, x=\pm 6\pi r$ &c., and each of which is divided into two symmetrical parts by the ordinates corresponding to one of the abscissæ $x=\pm \pi r, x=\pm 3\pi r, x=\pm 5\pi r$, &c. If now we differentiate the values

of x and y found above, we get $dx = r(1 - \cos \omega) d\omega = y d\omega, dy = r \sin \omega d\omega$; and hence $\frac{dy}{dx} = \frac{r \sin \omega}{y} =$

$\pm \frac{\sqrt{(2ry - y^2)}}{y} = \pm \sqrt{\left(\frac{2r}{y} - 1 \right)}$. Therefore we shall have respectively for the lengths of the sub-normal, sub-tangent, normal and tangent, the following values:

$$\pm r \sin \omega = \sqrt{(2ry - y^2)}, \quad y \sqrt{\frac{y}{2r - y}}, \quad \sqrt{(2ry)}, \quad y \sqrt{\left(\frac{2r}{2r - y} \right)}$$

By comparing the value of $x_1 - x = r \sin \omega$ with the value of $\frac{dy}{dx} = \frac{r \sin \omega}{y}$, we find $x_1 - x = y \frac{dy}{dx}$, when x_1 is

the abscissa of the centre of the generating circle, or which is the same thing, the abscissa of the point of contact of this circle with the axis of x . Now, the value we have just found for this abscissa is precisely the same as that of the abscissa of the point where the tangent meets the axis of x . Hence it is easy to conclude that if we draw a diameter parallel to the axis of y in the generating circle of the cycloid, the directions of the normal and tangent to this curve will be those of the straight lines drawn through the point (x, y) , taken on the curve, to the extremities of the diameter of the generating circle in the corresponding position. The length of the normal will be the length of the chord corresponding in the circle to the angle ω , and to obtain the sub-normal of the cycloid, it will be sufficient to project the radius drawn from the point (x_1, y_1) to the point (x, y) on the axis of x .

Let us find now the radius of curvature. Since $\frac{dy^2}{dx^2} = \frac{2r}{y} - 1$, we shall have $\frac{d^2y}{dx^2} = -\frac{r}{y^2}$, and

$y^3 \frac{d^2y}{dx^2} = -ry = -\frac{1}{2} N^2$, N being the length of the normal, and, consequently, $\rho = \frac{N^3}{\frac{1}{2} N^2} = 2N$. Therefore, in the

cycloid, the radius of curvature is double the normal, when the basis of the curve is taken for the axis of x . Hence, the radius of curvature becomes nothing at the same time as the normal, and the curvature is infinite in all the points where the cycloid meets the basis, that is to say, at all the points where the curve offers a cusp of the first kind, whilst, in all the points furthest from the basis, the radius of curvature becomes equal to double the diameter of the generating circle.

(303.) Let us suppose now that the abscissa is not taken for the independent variable. We shall have

$$\tan \theta = \pm \frac{dy}{dx}, \quad \theta = \tan^{-1} \frac{dy}{dx}, \quad d\theta = \frac{dx \frac{d^2y}{dx^2} - dy \frac{d^2x}{dx^2}}{dx^2 + dy^2}, \quad ds = \pm \sqrt{dx^2 + dy^2},$$

and $\frac{\theta}{\rho} = \pm \frac{dx \frac{d^2y}{dx^2} - dy \frac{d^2x}{dx^2}}{(dx^2 + dy^2)^{\frac{3}{2}}} = \pm \frac{dx \frac{d^2y}{dx^2} - dy \frac{d^2x}{dx^2}}{ds^3}$. In the particular case where the arc s is considered as

the independent variable, the last formula may be transformed in such a manner as to contain only the differential coefficients of the second order of the variables x and y with respect to s . For that purpose let us differentiate the equation $dx^2 + dy^2 = ds^2$ in considering ds as a constant quantity, we shall have $dx \frac{d^2x}{ds^2} + dy \frac{d^2y}{ds^2} = 0$, and consequently

$$\frac{d^2y}{ds^2} = -\frac{d^2x}{ds^2} = \frac{dx \frac{d^2y}{dx^2} - dy \frac{d^2x}{dx^2}}{dx^2 + dy^2} = \pm \frac{\{(d^2x)^2 + (d^2y)^2\}^{\frac{1}{2}}}{(dx^2 + dy^2)^{\frac{3}{2}}}, \quad \text{and} \quad \frac{dx \frac{d^2y}{dx^2} - dy \frac{d^2x}{dx^2}}{ds^2} = \pm \frac{\{(d^2x)^2 + (d^2y)^2\}^{\frac{1}{2}}}{ds^3}.$$

Hence we shall find for the length of the radius of curvature

$$\frac{1}{\rho} = \frac{\{(d^2x)^2 + (d^2y)^2\}^{\frac{1}{2}}}{ds^3} = \left\{ \left(\frac{d^2x}{ds^2} \right)^2 + \left(\frac{d^2y}{ds^2} \right)^2 \right\}^{\frac{1}{2}}$$

If we take from the point (x, y) on the curve and on its tangent, produced in the same direction as the arc s , equal and infinitely small lengths represented by i , we shall find, for the coordinates of the extremity of one of

these lengths, $x + i \frac{dx}{ds}$, $y + i \frac{dy}{ds}$, and for the coordinates of the other

$$x + i \frac{dx}{ds} + \frac{i^2}{2} \left(\frac{d^2x}{ds^2} + I \right), \quad y + i \frac{dy}{ds} + \frac{i^2}{2} \left(\frac{d^2y}{ds^2} + J \right).$$

I and J designating infinitely small quantities. Therefore, if we call l the distance between the extremities of these two lengths, we shall have

$$l = \frac{i^2}{2} \left\{ \left(\frac{d^2x}{ds^2} + I \right)^2 + \left(\frac{d^2y}{ds^2} + J \right)^2 \right\}^{\frac{1}{2}}, \quad \text{and consequently} \quad \left\{ \left(\frac{d^2x}{ds^2} \right)^2 + \left(\frac{d^2y}{ds^2} \right)^2 \right\}^{\frac{1}{2}} = \lim \frac{2l}{i^2}.$$

This formula, compared to the value of $\frac{1}{\rho}$ found above, gives $\rho = \lim \frac{i^2}{2l}$. Therefore to obtain the radius of cur-

vature of a curve in a given point, it is sufficient to take on this curve and on its tangent, produced in the same direction, equal and infinitely small lengths, and to divide the square of one of them by the double of the distance between their extremities. The limit of the quotient is the exact value of the radius of curvature.

(304.) To apply the formulæ we have given to the determination of the curvature of a curve, it is necessary to begin to express the differential coefficients of the first and second order of the coordinates x, y , in function of these coordinates and the differential of the independent variable. This calculation may be dispensed with by means of the formulæ we are going to develop.

Let $u = 0$ be the equation of the given curve, u designating a function of the rectangular coordinates x, y . By differentiating this equation twice, we shall find

$$\frac{du}{dx} dx + \frac{du}{dy} dy = 0, \quad \frac{d^2u}{dx^2} dx^2 + \frac{d^2u}{dy^2} dy^2 = - \left(\frac{d^2u}{dx^2} dx^2 + 2 \frac{d^2u}{dx dy} dx dy + \frac{d^2u}{dy^2} dy^2 \right),$$

and, consequently,

$$\left(\frac{du}{dx} \right) = - \left(\frac{du}{dy} \right) = \frac{dy \frac{d^2x}{dx^2} - dx \frac{d^2y}{dx^2}}{\frac{d^2u}{dx^2} dx^2 + \frac{d^2u}{dy^2} dy^2} = \pm \frac{(dx^2 + dy^2)^{\frac{1}{2}}}{\left\{ \left(\frac{du}{dx} \right)^2 + \left(\frac{du}{dy} \right)^2 \right\}^{\frac{1}{2}}}.$$

Therefore we shall have

$$\begin{aligned} dx \frac{d^2y}{dx^2} - dy \frac{d^2x}{dx^2} &= \mp \frac{(dx^2 + dy^2)^{\frac{1}{2}}}{\left\{ \left(\frac{du}{dx} \right)^2 + \left(\frac{du}{dy} \right)^2 \right\}^{\frac{1}{2}}} \left\{ \frac{d^2u}{dx^2} dx^2 + \frac{d^2u}{dy^2} dy^2 \right\} \\ &= \pm \frac{(dx^2 + dy^2)^{\frac{1}{2}}}{\left\{ \left(\frac{du}{dx} \right)^2 + \left(\frac{du}{dy} \right)^2 \right\}^{\frac{1}{2}}} \left\{ \frac{d^2u}{dx^2} dx^2 + 2 \frac{d^2u}{dx dy} dx dy + \frac{d^2u}{dy^2} dy^2 \right\} \end{aligned}$$

This last formula, combined with the value $\frac{1}{\rho} = \frac{dx \frac{d^2y}{dx^2} - dy \frac{d^2x}{dx^2}}{ds^3}$, leads to

$$\frac{1}{\rho} = \pm \frac{\frac{d^2 u}{dx^2} dx^2 + 2 \frac{d^2 u}{dx dy} dx dy + \frac{d^2 u}{dy^2} dy^2}{(dx^2 + dy^2) \left\{ \left(\frac{du}{dx} \right)^2 + \left(\frac{du}{dy} \right)^2 \right\}^{\frac{1}{2}}},$$

and then replacing the differentials dx, dy by the quantities $\frac{du}{dy}, \frac{du}{dx}$, which are proportional to them, we shall have finally

$$\frac{1}{\rho} = \pm \frac{\left(\frac{du}{dy} \right)^2 \frac{d^2 u}{dx^2} - 2 \frac{du}{dx} \frac{du}{dy} \frac{d^2 u}{dx dy} + \left(\frac{du}{dx} \right)^2 \frac{d^2 u}{dy^2}}{\left\{ \left(\frac{du}{dx} \right)^2 + \left(\frac{du}{dy} \right)^2 \right\}^{\frac{3}{2}}}.$$

If the variables x, y were separated, that is to say, if the function u were composed of two parts, one containing the variable x alone, and the other the variable y , $\frac{d^2 u}{dx dy}$ would be equal to nothing, and the preceding value would be reduced to

$$\frac{1}{\rho} = \pm \frac{\left(\frac{du}{dx} \right)^2 \frac{d^2 u}{dy^2} + \left(\frac{du}{dy} \right)^2 \frac{d^2 u}{dx^2}}{\left\{ \left(\frac{du}{dx} \right)^2 + \left(\frac{du}{dy} \right)^2 \right\}^{\frac{3}{2}}}.$$

These two formulæ applied to the examples which have been chosen will give the same values as we have already found for the radii of curvature.

(305.) Before leaving this subject it is necessary that in the formula $\frac{1}{\rho} = \pm \frac{d\theta}{ds}$, we may substitute to θ any one of the values which verify the equation $\tan \theta = \frac{dy}{dx}$, that is to say, a value of the form $\pm n\pi + \tan^{-1} \frac{dy}{dx} = \pm n\pi \pm \theta$, n being an integer, and if we designate this general value by ψ , we shall have $\frac{1}{\rho} = \pm \frac{d\psi}{ds}$.

The centre of curvature corresponding to the point (x, y) will be placed with respect to this last point on the side of the positive y , or negative y , according as the value of the ratio $\frac{d\psi}{dx}$ will be positive or negative. For the centre of curvature being the point of intersection of two normals infinitely near each other, it is clear that the curve will always turn its concavity towards this same centre. Hence, if x be taken for the independent variable, it is obvious that the centre of curvature will be situated with respect to the point (x, y) on the side of the positive y if the value of $\frac{d^2 y}{dx^2}$ be positive, and on the side of the negative y in the contrary case. But we

have, x being still the independent variable, $\frac{d\psi}{dx} = \frac{\frac{d^2 y}{dx^2}}{1 + \frac{dy^2}{dx^2}}$, therefore the two quantities $\frac{d\psi}{dx}$ and $\frac{d^2 y}{dx^2}$ will be, at

the same time, positive or negative, and the sign of the first may be consulted instead of the sign of the other. If, moreover, we observe that the value and the sign of $\frac{d\psi}{dx}$ will remain the same whatever be the independent variable, we shall have demonstrated the theorem stated above.

(306.) Let ρ be as above the radius of curvature of a plane curve corresponding to the point (x, y) , and x_1, y_1 the coordinates of the centre of curvature. This centre being the extremity of the radius ρ taken on the normal from the point (x, y) , on the side towards which the curve is concave, the coordinates x_1, y_1 will obviously verify the two equations $(x_1 - x)^2 + (y_1 - y)^2 = \rho^2$, $(x_1 - x) dx + (y_1 - y) dy = 0$, which give

$$\frac{y_1 - y}{dx} = \frac{x_1 - x}{-dy} = \pm \frac{\left\{ (y_1 - y)^2 + (x_1 - x)^2 \right\}^{\frac{1}{2}}}{(dx^2 + dy^2)^{\frac{1}{2}}} = \pm \frac{\rho}{ds}.$$

From the remark made in the last number, it results, that if ψ be one of the angles determined by the equation $\tan \psi = \frac{dy}{dx}$, $y_1 - y$ and the ratio $\frac{d\psi}{dx}$ will be quantities of the same sign. Hence we shall have

$\frac{y_1 - y}{dx} = \frac{x_1 - x}{-dy} = \frac{1}{d\psi}$, and consequently $y_1 - y = \frac{dx}{d\psi}$, $x_1 - x = -\frac{dy}{d\psi}$. These equations, which are both

Integral Calculus. included in the preceding, are sufficient to determine the coordinates of the centre of curvature of any plane curve. Part III

If we take x for the independent variable, we shall find in multiplying by dx , and substituting for $\frac{d\psi}{dx}$ its value

$$\frac{\left(\frac{d^2 y}{dx^2}\right)}{1 + \left(\frac{dy}{dx}\right)^2}, \text{ we find } y_1 - y = \frac{x_1 - x}{-\left(\frac{dy}{dx}\right)} = \frac{1 + \left(\frac{d^2 y}{dx^2}\right)}{\left(\frac{d^2 y}{dx^2}\right)}, \text{ or which is the same thing, } y_1 - y = \frac{1 + \left(\frac{d^2 y}{dx^2}\right)}{\left(\frac{d^2 y}{dx^2}\right)};$$

$$x_1 - x = -\frac{dy}{dx} \frac{1 + \left(\frac{d^2 y}{dx^2}\right)}{\left(\frac{d^2 y}{dx^2}\right)}.$$

If x be not taken for the independent variable, the equation $\tan \psi = \frac{dy}{dx}$ will give $\frac{d\psi}{\cos^2 \psi} = d \frac{dy}{dx}$
 $= \frac{dx d^2 y - dy d^2 x}{dx^2}$, and $d\psi = \frac{1}{1 + \tan^2 \psi} \frac{dx d^2 y - dy d^2 x}{dx^2} = \frac{dx d^2 y - dy d^2 x}{dx^2 + dy^2}$, and therefore the formula
 $\frac{y_1 - y}{dx} = \frac{x_1 - x}{-dy} = \frac{1}{d\psi}$ will become $\frac{y_1 - y}{dx} = \frac{x_1 - x}{-dy} = \frac{dx^2 + dy^2}{dx d^2 y - dy d^2 x}$, or $y_1 - y = dx \frac{dx^2 + dy^2}{dx d^2 y - dy d^2 x}$,
 $x_1 - x = -dy \frac{dx^2 + dy^2}{dx d^2 y - dy d^2 x}$, from which it is easy to deduce $(x_1 - x) d^2 x + (y_1 - y) d^2 y = dx^2 + dy^2 = ds^2$,
 or which is the same thing, $(x_1 - x) \frac{d^2 x}{ds^2} + (y_1 - y) \frac{d^2 y}{ds^2} = 1$.

It is easy to find this last formula in a more direct manner. Let λ and μ be the angles which the normal, produced on the side towards which the curve turns its concavity, makes with the positive axis of x and y . We shall have clearly $\frac{x_1 - x}{\rho} = \cos \lambda$, $\frac{y_1 - y}{\rho} = \cos \mu$. Let us conceive also, that s is taken for the independent variable, and that from the point (x, y) we take on the normal and on the curve, produced in the same direction, equal and infinitely small lengths represented by i . Then if we call l the distance between the extremities of these two lengths, the distance l , reckoned from the tangent, will have for its algebraical projections on the axis quantities of the form $\frac{i^2}{2} \left(\frac{d^2 x}{ds^2} + I \right)$, $\frac{i^2}{2} \left(\frac{d^2 y}{ds^2} + J \right)$, I and J representing infinitely small quantities, and will form consequently with the same axis produced in the direction of the positive coordinates angles which will have for cosines $\frac{i^2}{2l} \left(\frac{d^2 x}{ds^2} + I \right)$, $\frac{i^2}{2l} \left(\frac{d^2 y}{ds^2} + J \right)$. But according to number (299.) the line l will be very nearly parallel to the normal; and as this length ought to be taken from the tangent, on the side where is the centre of curvature, we are allowed to conclude that the limits of the last expressions will be equivalent to the cosines of the angles λ and μ . This understood, if we reduce I and J to nothing, and substitute for $\frac{i^2}{2l}$ its limit ρ , we shall have $\rho \frac{d^2 x}{ds^2} = \cos \lambda$, $\rho \frac{d^2 y}{ds^2} = \cos \mu$. If the arc s were not taken for the independent variable, we ought to replace $\frac{d^2 x}{ds^2}$, $\frac{d^2 y}{ds^2}$ by $\frac{d \left(\frac{dx}{ds} \right)}{ds}$, $\frac{d \left(\frac{dy}{ds} \right)}{ds}$, and then the values of $\cos \lambda$ and $\cos \mu$ would be $\cos \lambda = \rho \left(\frac{d^2 x}{ds^2} - dx \frac{d^2 s}{ds^3} \right)$, $\cos \mu = \rho \left(\frac{d^2 y}{ds^2} - dy \frac{d^2 s}{ds^3} \right)$. If now we multiply the last equations by the two, $\cos \lambda = \frac{x_1 - x}{\rho}$, $\cos \mu = \frac{y_1 - y}{\rho}$, and if we add them, we shall find the equation which we proposed to demonstrate

$$(x_1 - x) \frac{d^2 x}{ds^2} + (y_1 - y) \frac{d^2 y}{ds^2} = 1.$$

In the particular case where s is taken for the independent variable, we have

$$x_1 - x = \rho^2 \frac{d^2 x}{ds^2} = \frac{dx^2 + dy^2}{(d^2 x)^2 + (d^2 y)^2} d^2 x, \quad y_1 - y = \rho^2 \frac{d^2 y}{ds^2} = \frac{dx^2 + dy^2}{(d^2 x)^2 + (d^2 y)^2} d^2 y.$$

The same formulæ are obtained by substituting in the formulæ

$$y_1 - y = dx \frac{dx^2 + dy^2}{dx d^2 y - dy d^2 x}, \quad x_1 - x = dy \frac{dx^2 + dy^2}{dx d^2 y - dy d^2 x},$$

Integral Calculus. the quantities $d^2 y$, $d^2 x$ to the quantities dx and $-dy$ to which they are respectively proportional, since $d^2 s$ or $d^2 x + d^2 y = 0$. Part III.

We have thus found between the quantities x, y, x_1, y_1 and ρ the three following equations:

$$(x_1 - x)^2 + (y_1 - y)^2 = \rho^2, (x_1 - x) dx + (y_1 - y) dy = 0, (x_1 - x) d^2 x + (y_1 - y) d^2 y - dx^2 - dy^2 = 0,$$

which are sufficient to determine in function of x the three unknown x_1, y_1 , and ρ . It is essential to remark that the second and third equations may be found by differentiating the first two consecutive times, and in considering x_1, y_1 , and ρ , as constant quantities.

(307.) When the point (x, y) changes its place on the curve, the centre of curvature changes at the same time. If the first point be supposed to move in a continuous manner, the second will describe a new curve. To obtain the equation of this last curve, it will obviously be sufficient to express in function of one variable only, x, y or s the values of x_1 and y_1 , and to eliminate this variable between the two values. The equation resulting from the elimination will contain only the two variables x_1 and y_1 , and will represent the line which is the locus of all the centres of curvature of the given curve. To discover the principal properties of this curve, we shall differentiate the two first of the three above equations. We shall have $(x - x_1) dx_1 + (y - y_1) dy_1 = \rho d\rho$, and $dx dx_1 + dy dy_1 = 0$. From the last of these two equations it results that the tangents drawn to the given curve through the point (x, y) and to the new curve through the point (x_1, y_1) are perpendicular to each other. Therefore the radius of curvature, which is reckoned on the normal drawn to the first curve through the point (x, y) , and which ends at the point (x_1, y_1) , will be, in this last point, tangent to the second curve. Moreover, if we call s_1 the arc of the new curve, contained between a fixed point and the point (x_1, y_1) , we shall have $dx_1^2 + dy_1^2 = ds_1^2$, and this combined with the above equations will give

$$\frac{dx_1}{x_1 - x} = \frac{dy_1}{y_1 - y} = \frac{(x_1 - x) dx_1 + (y_1 - y) dy_1}{\rho^2} = \pm \frac{\sqrt{dx_1^2 + dy_1^2}}{\rho} = \frac{d\rho}{\rho} = \pm \frac{ds_1}{\rho}.$$

Hence $d\rho = \pm ds_1$, or $d(\rho \pm s_1) = 0$. If, for more facility, we make $\rho \mp s_1 = \phi(x)$, we shall have $\frac{d\phi(x)}{dx} = 0$;

then if we designate by Δx a finite increment of x , and by $\Delta \phi(x)$ the corresponding increment of $\rho \mp s_1$, and by θ a number inferior to one, we shall have $\Delta \phi(x) = \phi(x + \Delta x) - \phi(x) = \frac{d \cdot (x + \theta \Delta x)}{dx} \cdot \Delta x = 0$. Hence

we shall have $\Delta(\rho \mp s_1) = 0$, or $\Delta\rho = \pm \Delta s_1$. This last equation shows that the arc $\pm \Delta s_1$ between two points of the new curve is equal to the difference of the radii of curvature which end at these points. The sign placed before the difference Δs_1 in the equation $\Delta\rho = \pm \Delta s_1$ will always be the same as that which will precede the

ratio $\frac{ds_1}{\rho}$ in the formula $\frac{dx_1}{x_1 - x} = \frac{dy_1}{y_1 - y} = \pm \frac{ds_1}{\rho}$, or the ratios $\frac{x_1 - x}{\rho}$, $\frac{y_1 - y}{\rho}$ in the two equations $\frac{dx_1}{ds_1} = \pm \frac{x_1 - x}{\rho}$, $\frac{dy_1}{ds_1} = \pm \frac{y_1 - y}{\rho}$. It results from this, that the arc s_1 and the radius of curvature ρ will increase

simultaneously if the tangent to the new curve, being produced in the same direction as the arc s_1 , coincide, not with the radius of curvature ρ , but with the producement of this radius beyond the point (x_1, y_1) , whilst in the contrary hypothesis, the radius ρ increasing, the arc s_1 will decrease. This understood, let us conceive that a thread is fixed by one of its extremities to the point (x_1, y_1) , let its length be equal to ρ , and let us first suppose that it is applied on the radius ρ . If then this thread, remaining constantly stretched, moves in such a manner that one part is wrapt up, the arc Δs_1 , contained between the point (x_1, y_1) and the point $(x_1 + \Delta x_1, y_1 + \Delta y_1)$, the other part which will remain straight, and will touch the new curve at the point $(x_1 + \Delta x_1, y_1 + \Delta y_1)$, will obviously have a length equal to the radius of curvature which ends at that point. Consequently, that of the extremities of the thread which first coincided with the point (x, y) will coincide now with the point $(x + \Delta x, y + \Delta y)$. As this last point is situated on the proposed curve, and that our reasoning holds whatever be the length of the arc $\pm \Delta s_1$, we may conclude that the extremity of the thread which is not fixed, will describe the proposed curve. The same curve will also be described, but in a contrary direction, if after having been applied on the arc $\pm \Delta s_1$, the thread moves so as to come back to its primitive position; and, in this retrograde motion, the portion of the thread unwrapped will be stretched in a straight line. From this remark are derived a few expressions, generally used, and which it is necessary to know. The new curve is called the *evolute* of the proposed curve, and the proposed curve, described by the free extremity of the thread, is called the *involute* of the new curve.

(308.) To show an application of the above formulæ, let us propose to find the locus of the centres of curvature of the cycloid, or, in other words, the evolute of that curve. The cycloid is represented by the two equations

$$x = r(\omega - \sin \omega), y = r(1 - \cos \omega) \quad (302.) \text{ from which we get } \tan \psi = \frac{dy}{dx} = \frac{r \sin \omega}{y} = \frac{\sin \omega}{1 - \cos \omega} = \cot \frac{\omega}{2},$$

and $\psi = \pm n\pi + \frac{\pi - \omega}{2}$, n designating any integer whatever. Hence we have $d\psi = -\frac{1}{2} d\omega$, and the formulæ

$$y_1 - y = \frac{dx}{d\psi}, x_1 - x = -\frac{dy}{d\psi} \text{ will give } x_1 = x + 2\frac{dy}{d\omega}, y_1 = y - 2\frac{dx}{d\omega}. \text{ If now we substitute for } x, y, \text{ and}$$

dx, dy their values, we shall find $x_1 = x + 2r \sin \omega = r(\omega + \sin \omega)$, $y_1 = -y = -r(1 - \cos \omega)$, and if we assume $\omega = \Omega + \pi$ we shall obtain $x_1 - \pi r = r(\Omega - \sin \Omega)$, $y_1 + 2r = r(1 - \cos \Omega)$, which represent the

Integral
Calculus.

Part III.

evolute of the cycloid. This curve will obviously pass through the point which has for its coordinates $x = \pi r$, $y = -2r$, and is the centre of curvature corresponding to the ordinate that is a maximum in the first branch. In order to place the origin of coordinates at this centre, it is sufficient to substitute $x_1 + \pi r$ for x , and $y_1 - 2r$ for y , so that the two equations become $x_1 = r(\Omega - \sin \Omega)$, $y_1 = r(1 - \cos \Omega)$. These two equations do not differ from the two equations which represent the given cycloid, therefore we may conclude that the evolute of a cycloid is another cycloid of the same form and of the same dimensions, the cusps of which coincide with the centres of curvature of the middle points of the several branches of the first. It is also obvious, that the cusps of the first are, at the same time, the middle points of the several branches of the second cycloid, and that the second cycloid being represented by the two equations $x_1 - \pi r = r(\Omega - \sin \Omega)$, $y_1 + 2r = r(1 - \cos \Omega)$, its basis coincides with the straight line which is represented by the equation $y_1 = -2r$.

The two equations $x_1 = x + 2r \sin \omega = r(\omega + \sin \omega)$, $y_1 = -y = -r(1 - \cos \omega)$ may be easily derived from the property we have demonstrated, namely, that in the cycloid, the radius of curvature is double the normal when the basis is taken for axis of x . In consequence of this proposition, the middle point of the radius of curvature,

that is to say, the point the coordinates of which are $\frac{x + x_1}{2}$, $\frac{y + y_1}{2}$, coincides with the point in which the basis is

touched by the generating circle, the abscissa of which is $r\omega = x + r \sin \omega$. We have, therefore, the equations

$$\frac{x + x_1}{2} = x + r \sin \omega, \quad \frac{y + y_1}{2} = 0, \text{ from which we may immediately derive the values given above for } x_1 \text{ and } y_1.$$

It is also possible, without using these formulæ, to determine the nature of the evolute of the cycloid. For that purpose, let us describe with the radius r two equal circles, having their centres placed upon the axis of y , the one above, the other below the axis of x , both touching this last axis, at the origin of coordinates. Let us conceive, moreover, that both these circles are made to roll, the first on the axis of x , and the second on the straight line $y = -2r$, parallel to it, so that the axis of x remains tangent to both. The radii which, in the first instant, passed through the origin of coordinates will turn round the centres, and describe, in the same time, equal angles; hence it results, 1. That these radii will be parallel in every position of the circles; 2. That the straight line joining their extremities will pass through the point of contact, and will be bisected at that point. But the part line inscribed, in the first circle, is equal to the normal of the proposed cycloid described by the extremity of the first radius, therefore the radius of curvature of this curve, which is equal to double the normal, will necessarily coincide with the whole line, and the centre of curvature with the extremity of the second radius. Hence, the locus of the centres of curvature, or the evolute of the first cycloid, will be precisely the second cycloid described by the extremity of the second radius.

(309.) Let again $u = 0$ be the equation of a plane curve, u being a function of the two coordinates x and y . By combining the following equations, which have been obtained,

$$(x_1 - x) dx + (y_1 - y) dy = 0, \quad (x_1 - x) d^2 x + (y_1 - y) d^2 y = ds^2, \quad \frac{du}{dx} dx + \frac{du}{dy} dy = 0,$$

$$\frac{du}{dx} d^2 x + \frac{du}{dy} d^2 y = - \left(\frac{d^2 u}{dx^2} dx^2 + 2 \frac{d^2 u}{dx dy} dx dy + \frac{d^2 u}{dy^2} dy^2 \right) = 0,$$

we shall find

$$\frac{x_1 - x}{\left(\frac{du}{dx}\right)} = \frac{y_1 - y}{\left(\frac{du}{dy}\right)} = \frac{(x_1 - x) d^2 x + (y_1 - y) d^2 y}{\frac{du}{dx} d^2 x + \frac{du}{dy} d^2 y} = - \frac{dx^2 + dy^2}{\frac{d^2 u}{dy^2} dy^2 + 2 \frac{d^2 u}{dx dy} dx dy + \frac{d^2 u}{dx^2} dx^2},$$

and then substituting for the differentials dx , dy , the quantities $\frac{du}{dy}$, $-\frac{du}{dx}$, which are respectively proportional to them, we shall find

$$\frac{x_1 - x}{\left(\frac{du}{dx}\right)} = \frac{y_1 - y}{\left(\frac{du}{dy}\right)} = \frac{\left(\frac{du}{dx}\right)^2 + \left(\frac{du}{dy}\right)^2}{\left(\frac{du}{dx}\right)^2 \frac{d^2 u}{dy^2} - 2 \frac{du}{dx} \cdot \frac{du}{dy} \cdot \frac{d^2 u}{dx dy} + \left(\frac{du}{dy}\right)^2 \frac{d^2 u}{dx^2}}.$$

If in the equation $u = 0$, the variables x and y are separated, we have $\frac{d^2 u}{dx dy} = 0$, and the preceding formula becomes

$$\frac{x_1 - x}{\left(\frac{du}{dx}\right)} = \frac{y_1 - y}{\left(\frac{du}{dy}\right)} = - \frac{\left(\frac{du}{dx}\right)^2 + \left(\frac{du}{dy}\right)^2}{\left(\frac{du}{dx}\right)^2 \frac{d^2 u}{dy^2} + \left(\frac{du}{dy}\right)^2 \frac{d^2 u}{dx^2}}.$$

To obtain the equation of the evolute of the curve represented by the equation $u = 0$, it will be sufficient to eliminate x and y between this equation and the two furnished by the preceding formula, or the one before, according as the variables x and y will or will not be separated in u . In several cases it is easy to resolve the two last equations, just mentioned, with respect to the variables x and y , and to deduce from them the values of x and y in function of the coordinates x_1 and y_1 . Then in substituting these values in the equation $u = 0$, the equation of the evolute is immediately obtained.

Integral
Calculus.(310.) Let us take for first example the ellipse represented by the equation $\frac{x^2}{a^2} + \frac{y^2}{b^2} = 1$. In this particular Part III.

case the variables are separated, and we may take $u = \frac{1}{2} \left(\frac{x^2}{a^2} + \frac{y^2}{b^2} - 1 \right)$. Hence we shall have

$$\frac{du}{dx} = \frac{x}{a^2}, \quad \frac{du}{dy} = \frac{y}{b^2}, \quad \frac{d^2u}{dx^2} = \frac{1}{a^2}, \quad \frac{d^2u}{dy^2} = \frac{1}{b^2},$$

consequently,

$$\left(\frac{du}{dx} \right)^2 \frac{d^2u}{dy^2} + \left(\frac{du}{dy} \right)^2 \frac{d^2u}{dx^2} = \frac{1}{a^2 b^2} \left(\frac{x^2}{a^2} + \frac{y^2}{b^2} \right) = \frac{1}{a^2 b^2}.$$

And therefore, by means of the above formula, for the case in which the variables are separated,

$$a^2 \left(\frac{x_1}{x} - 1 \right) = b^2 \left(\frac{y_1}{y} - 1 \right) = - \left(b^2 \frac{x^2}{a^2} + a^2 \frac{y^2}{b^2} \right) = -a^2 + \frac{a^2 - b^2}{a^2} x^2 = -b^2 + \frac{b^2 - a^2}{b^2} y^2.$$

From this formula we derive $a^2 \frac{x_1}{x} = \frac{a^2 - b^2}{a^2} x^2$, $\frac{b^2 y_1}{y} = \frac{b^2 - a^2}{b^2} y^2$, and if we represent by A and B two positive quantities chosen in such a manner as to verify the formula $\pm (a^2 - b^2) = A a = B b$, we shall find $\frac{x_1}{A} = \pm \frac{x^2}{a^2}$,

$\frac{y_1}{B} = \mp \frac{y^2}{b^2}$, or, which is the same thing, $\frac{x}{a} = \pm \left(\frac{x_1}{A} \right)^{\frac{1}{2}}$, $\frac{y}{b} = \mp \left(\frac{y_1}{B} \right)^{\frac{1}{2}}$. If we substitute now these values in

the equation of the ellipse, we shall obtain for the equation of the evolute of that curve $\left(\frac{x_1}{A} \right)^{\frac{2}{3}} + \left(\frac{y_1}{B} \right)^{\frac{2}{3}} = 1$.

This equation may easily be transformed so as to contain only integral powers of the variables x and y . For that, it suffices to raise each side of the equation to the third power, we shall find

$$1 - \frac{x_1^2}{A^2} - \frac{y_1^2}{B^2} = 3 \left(\frac{x_1 y_1}{A B} \right)^{\frac{2}{3}} \left\{ \left(\frac{x_1}{A} \right)^{\frac{2}{3}} + \left(\frac{y_1}{B} \right)^{\frac{2}{3}} \right\} = 3 \left(\frac{x_1 y_1}{A B} \right)^{\frac{2}{3}}, \text{ and, finally, } \left(1 - \frac{x_1^2}{A^2} - \frac{y_1^2}{B^2} \right)^3 = 27 \frac{x_1^2}{A^2} \cdot \frac{y_1^2}{B^2}.$$

From either of these equations it is easy to conclude that the evolute of the ellipse is a curve completely shut, divided into four equal parts by two rectangular axes which coincide, as those of the ellipse, with the coordinate axis. Each part of the evolute is tangent to the axis where it meets them, and each of these points is, at the same time, a cusp of the first kind.

Let us next consider the hyperbola represented by the equation $\frac{x^2}{a^2} - \frac{y^2}{b^2} = \pm 1$. By operating as in the preceding example, and designating by A and B two positive quantities, chosen in such a manner as to verify the

formula $a^2 \pm b^2 = A a = B b$, we shall find for the equation of the evolute of the hyperbola $\left(\frac{x_1}{A} \right)^{\frac{2}{3}} - \left(\frac{y_1}{B} \right)^{\frac{2}{3}} = \pm 1$,

or, which is the same thing, $\left\{ 1 \mp \left(\frac{x_1^2}{A^2} - \frac{y_1^2}{B^2} \right) \right\}^3 = -27 \frac{x_1^2}{A^2} \frac{y_1^2}{B^2}$. From either of these equations it is also easy to

conclude that the evolute of the hyperbola is a curve divided into four equal parts by the coordinate axis, and composed of two infinite branches separated from each other, each of which has a cusp situated on the production of the real axis $2a$, or $2b$, of the hyperbola, at the distance A or B from the origin.

Let us take for a last example the parabola represented by the equation $y^2 = 2px$, where p is supposed to be a positive quantity. In this case, we may take $u = \frac{1}{2} (2px - y^2)$, from which equation we derive $\frac{du}{dx} = p$,

$\frac{du}{dy} = -y$, $\frac{d^2u}{dx^2} = 0$, $\frac{d^2u}{dy^2} = -1$, and hence $\frac{x_1 - x}{p} = 1 - \frac{y_1}{y} = 1 + \frac{y^2}{p^2} = \frac{p + 2x}{p}$. We shall have, there-

fore, $x_1 - x = p + 2x$, $-\frac{y_1}{p} = \frac{y^2}{p^2}$, or, which is the same thing, $x_1 = p + 3x$, $y^2 = -p^2 \frac{y_1}{p}$, or $x = \frac{x_1 - p}{3}$,

$y = -p^{\frac{2}{3}} y_1^{\frac{1}{3}}$. Substituting these values in the equation of the parabola, and suppressing the factor p common

to both sides, we shall find $\frac{2}{3} (x_1 - p) = p^{\frac{1}{3}} y_1^{\frac{2}{3}}$. This equation, which may be put under the form $\frac{8}{27} (x_1 - p)^3$

$= p y_1^2$, represents the evolute of the parabola. It is easy to verify that this evolute extends infinitely on the side of the positive abscissæ, that it has for its axis the axis of the parabola, and that it meets this axis, in touching it, at the point the abscissa of which is p . This point, which is placed at the same distance from the focus as the summit of the parabola, is at the same time the summit of the evolute, and the only cusp it presents. To place the origin of coordinates at that point, it suffices to substitute $x_1 + p$ for x_1 in the preceding equation. And we shall have

$$x_1 = \frac{3}{2} p^{\frac{1}{3}} y_1^{\frac{2}{3}}, \quad y_1 = \left(\frac{2}{3}\right)^{\frac{3}{2}} p^{\frac{1}{2}} x_1^{\frac{3}{2}}.$$

This shows that any parabola of the second degree has for evolute a parabola of the degree $\frac{2}{3}$ or $\frac{3}{2}$.

(311.) When two curves having a common point, have, at the same time, not only the same tangent but also the same osculating circle, and, consequently, the same curvature, with their concavities turned towards the same side, the contact which exists between the two curves takes the name of *osculation*, and one of the curves is said to be an osculating curve of the other. This definition understood, the following proposition follows immediately.

Let us conceive that two plane curves are represented by two equations between the rectangular coordinates x, y , and that the abscissa x is taken for the independent variable. In order that one of the curves should be an osculating curve to the other in a common point, corresponding to the abscissa x , it will be necessary and sufficient that the ordinate y relative to that abscissa, and the first and second differential coefficients of y , that is to say, $y, \frac{dy}{dx}, \frac{d^2y}{dx^2}$ should preserve, in passing from one curve to the other, the same numerical values and the same signs.

For, if these conditions are fulfilled, the two curves will obviously have a common point corresponding to the abscissa x . Moreover the two curves will have the same tangent, the same radius of curvature, and their convexities turned the same side. Reciprocally, if one of the curves is an osculating curve of the other, at the point the abscissa of which is x , not only the quantities $y, \frac{dy}{dx}$, and the sign of $\frac{d^2y}{dx^2}$ ought to remain the same in passing from one curve to the other, but it is clear that the same thing may be said with respect to the radius of curvature ρ , and the numerical value of $\frac{d^2y}{dx^2}$.

If x were not taken for the independent variable, the differential coefficient of the first order is still equal to $\frac{dy}{dx}$,

but the differential coefficient of the second order becomes equal $\frac{dx \frac{d^2y}{dx^2} - dy \frac{d^2x}{dx^2}}{dx^3} = \frac{d \cdot \left(\frac{dy}{dx}\right)}{dx}$. Let r be the independent variable, and let $r = f(x, y)$. By differentiating this equation two consecutive times, we find

$$1 = \frac{d \cdot f(x, y)}{dx} \cdot \frac{dx}{dr} + \frac{d \cdot f(x, y)}{dy} \cdot \frac{dy}{dr},$$

$$0 = \frac{d \cdot f(x, y)}{dx} \cdot \frac{d^2x}{dr^2} + \frac{d \cdot f(x, y)}{dy} \cdot \frac{d^2y}{dr^2} + \frac{d^2 f(x, y)}{dx^2} \frac{dx^2}{dr^2} + 2 \frac{d^2 f(x, y)}{dx dy} \frac{dx dy}{dr^2} + \frac{d^2 f(x, y)}{dy^2} \frac{dy^2}{dr^2}.$$

From these equations, it will be easy to derive the values of $\frac{dx}{dr}, \frac{dy}{dr}, \frac{d^2x}{dr^2}, \frac{d^2y}{dr^2}$, expressed in function of the quantities

$$\frac{dy}{dx}, \frac{d^2y}{dx^2}, \frac{d \cdot f(x, y)}{dx}, \frac{d f(x, y)}{dy}, \frac{d^2 f(x, y)}{dx^2}, \frac{d^2 f(x, y)}{dx dy}, \frac{d^2 f(x, y)}{dy^2}.$$

And since these last quantities will preserve the same values, at the point of osculation of two plane curves in passing from one curve to another, it is clear that the same thing may be said of the quantities $\frac{dx}{dr}, \frac{dy}{dr},$

$$\frac{d^2x}{dr^2}, \frac{d^2y}{dr^2}.$$

If, for instance, we take for the independent variable the radius vector drawn through the origin to the point (x, y) we shall have

$$r = \sqrt{(x^2 + y^2)}, \quad 1 = \frac{x}{r} \frac{dx}{dr} + \frac{y}{r} \frac{dy}{dr}, \quad 0 = \frac{x}{r} \frac{d^2x}{dr^2} + \frac{y}{r} \frac{d^2y}{dr^2} + \frac{1}{r^3} \left(y \frac{dx}{dr} - x \frac{dy}{dr} \right)^2, \text{ and these combined with}$$

the formula $\frac{d^2y}{dx^2} = \frac{dx \frac{d^2y}{dx^2} - dy \frac{d^2x}{dx^2}}{dx^3}$, give

$$\frac{dx}{dr} = \frac{\sqrt{(x^2 + y^2)}}{x + y \left(\frac{dy}{dx}\right)}, \quad \frac{dy}{dr} = \frac{\frac{dy}{dx} \sqrt{(x^2 + y^2)}}{x + y \left(\frac{dy}{dx}\right)}, \quad \frac{d^2x}{dr^2} = - \frac{\left(y - x \frac{dy}{dx}\right)^2 + y \frac{d^2y}{dx^2} (x^2 + y^2)}{\left(x + y \frac{dy}{dx}\right)^3},$$

$$\frac{d^2y}{dr^2} = - \frac{\frac{dy}{dx} \left(y - x \frac{dy}{dx}\right)^2 - x \frac{d^2y}{dx^2} (x^2 + y^2)}{\left(x + y \frac{dy}{dx}\right)^3}.$$

Integral
Calculus.

If we take for the independent variable the arc s , between the point (x, y) and a fixed point, and if we suppose that this arc is produced in the same direction beyond the point of contact for both curves. We have then Part III.

$dx^2 + dy^2 = ds^2$, $dx d^2x + dy d^2y = 0$, which, combined with the value of $\frac{d^2y}{dx^2} = \frac{dx d^2y - dy d^2x}{dx^3}$, will give

$$\frac{dx}{ds} = \pm \frac{1}{\sqrt{1 + \frac{dy^2}{dx^2}}}, \quad \frac{dy}{ds} = \frac{\frac{dy}{dx}}{\sqrt{1 + \frac{dy^2}{dx^2}}}, \quad \frac{d^2x}{ds^2} = -\frac{\frac{dy}{dx} \cdot \frac{d^2y}{dx^2}}{\left(1 + \frac{dy^2}{dx^2}\right)^{\frac{3}{2}}}, \quad \frac{d^2y}{ds^2} = \frac{\frac{d^2y}{dx^2}}{\left(1 + \frac{dy^2}{dx^2}\right)^{\frac{3}{2}}}.$$

The sign $+$ is to be taken when the arc s increases at the same time as the abscissa, and the sign $-$ in the contrary case. Hence we may conclude that for a point of osculation of two plane curves, the four quantities

$\frac{dx}{ds}$, $\frac{dy}{ds}$, $\frac{d^2x}{ds^2}$, $\frac{d^2y}{ds^2}$ preserve the same numerical values and the same signs in passing from the first curve to

the second. When it is proposed to verify whether a point, common to two plane curves, is a point of osculation, we may substitute to the differential coefficients, the differentials themselves, and consequently, the following proposition is established.

Two plane curves being represented by two equations between the coordinates x, y , to ascertain whether one of the curves is an osculating curve of the other, in a given point, common to both, it will be sufficient to take for the independent variable, either a determinate function of the variables x, y , or the arc s , reckoned on each curve from a fixed point, and to examine if, for the given point, the same values of x, y, dx, dy, d^2x, d^2y , may be derived from the equations of the two curves.

If we suppose the second curve to be a circle represented by the equation $(x - x_1)^2 + (y - y_1)^2 = \rho^2$, the conditions which express that the point (x, y) is a point of osculation will suffice to determine the radius of the circle, and the coordinates of the centre, that is to say the three quantities x_1, y_1 and ρ . For if we take x for the

independent variable, the values of $y, \frac{dy}{dx}, \frac{d^2y}{dx^2}$, derived from the equation of the first curve and its derived

equations, ought to satisfy to the equation of the circle, and to its differential equations of the first and second order,

that is to say, to the three formulæ $(x - x_1)^2 + (y - y_1)^2 = \rho^2$, $(x - x_1) + (y - y_1) \frac{dy}{dx} = 0$, $1 + \frac{dy^2}{dx^2} + (y - y_1) \frac{d^2y}{dx^2} = 0$.

When the values of the three unknown quantities x_1, y_1 and ρ , are determined by means of these

formulæ, the same results are found as we have obtained before.

If x were not taken for the independent variable, then the equation of the circle, and its two differential equations of the first and second order, might be presented under the form $(x - x_1)^2 + (y - y_1)^2 = \rho^2$, $(x - x_1) dx + (y - y_1) dy = 0$, $(x - x_1) d^2x + (y - y_1) d^2y + dx^2 + dy^2 = 0$, and ought to be verified by the values x, y, dx, dy, d^2x, d^2y , derived from the equation of the first curve. It is almost useless to remark that these last considerations respecting osculating curves, agree with the generalities, given before, respecting the contact of different orders which may exist between two curves.

(312.) In the preceding pages we have supposed, in general, that a plane curve was represented by an equation between two rectangular coordinates x, y . But it is often useful to substitute for these coordinates the polar coordinates r and p , r being the length of the radius vector drawn from the origin to the point, and p the angle which this line makes with the direction of the positive axis of x . The new coordinates are then connected with x and y by the two equations $x = r \cos p$, $y = r \sin p$. We shall now point out some of the results to which the consideration of polar coordinates may lead.

Let us first remark that the quantity r by which we designate the radius vector drawn from the origin or pole to any point, should always be considered as a positive quantity. As to the angle p formed by this radius vector and a given semi-axis, it may be positive or negative, and receive a numerical value inferior or superior to 2π . For more facility we shall call the semi-axis of the positive x from which the angle p is reckoned, semi-polar axis.

This understood, it is obvious, 1. That the equation of any circle having the origin for its centre will be $r = R$, R being a positive quantity equal to the radius of the circle; 2. That the equation of any semi-axis drawn from the origin will be $p = P$, P being a constant quantity positive or negative. It may be added that this equation $p = P$ will still represent the same semi-axis, if the quantity P is increased or diminished by any even multiple of π . Lastly, the semi-axis under consideration will be replaced by another in the same straight line, but in an inverse direction when the angle P is increased or diminished by an odd number of times π .

(313.) When a plane curve is represented by an equation between the rectangular coordinates x, y , we may easily, by means of the formulæ $x = r \cos p$, $y = r \sin p$, substitute for the variables x, y the polar coordinates, and obtain what is called the polar equation of the curve. Thus, for instance, if we call x_1, y_1 the rectangular coordinates of a fixed point, and R and P its polar coordinates, we have $x_1 = R \cos P$, $y_1 = R \sin P$. The straight line drawn through this point so as to form the angle ψ with the semi-axis of positive x , has for its equation, in rectangular

coordinates, $\frac{y - y_1}{x - x_1} = \tan \psi$, or $\frac{x - x_1}{\cos \psi} = \frac{y - y_1}{\sin \psi}$, and for the polar equation $\frac{r \cos p - R \cos P}{\cos \psi} = \frac{r \sin p - R \sin P}{\sin \psi}$,

or, which is the same thing, $r \sin(p - \psi) = R \sin(P - \psi)$. If the length R become equal to nothing, the

straight line will pass through the origin, and its polar equation will become $\sin(p - \psi) = 0$. This will be verified, in taking for n any integer whatever, by making $p = \psi \pm 2n\pi$, or $p = \psi \pm (2n + 1)\pi$. Each of these formulæ is similar to the equation $p = P$, and represents one of the semi-axes coinciding with the given straight line but in opposite directions, and both passing through the origin. We may easily, in the equation $r \sin(p - \psi) = R \sin(P - \psi)$, substitute the angle $p - P$ for the angle $p - \psi$. For, $p - \psi = (p - P) + (P - \psi)$, consequently $\sin(p - \psi) = \sin(p - P) \cos(P - \psi) + \sin(P - \psi) \cos(p - P)$, and this value being substituted, gives

$$\frac{r \cos(p - P) - R}{\cos(\psi - P)} = \frac{r \sin(p - P)}{\sin(\psi - P)}, \text{ or, which is the same thing, } \frac{r \cos(p - P) - R}{r \sin(p - P)} = \cot(\psi - P).$$

If, from the point (x_1, y_1) as a centre, with the radius ρ , we describe a circle, this circle, represented by the formula $(x - x_1)^2 + (y - y_1)^2 = \rho^2$, will have clearly for its polar equation $(r \cos p - R \cos P)^2 + (r \sin p - R \sin P)^2 = \rho^2$, or $r^2 - 2Rr \cos(p - P) + R^2 = \rho^2$. In the particular case where the centre coincides with the origin, R vanishes, and the equation is reduced to $r^2 = \rho^2$ or $r = \rho$. It is also very easy to verify that the two parabolas, and the ellipse or hyperbola, represented by the three equations $y^2 = 2ax$, $y^2 = -2ax$, $Ax^2 + 2Bxy + Cy^2 = \kappa$,

have respectively for their polar equations $r = \frac{2a \cos p}{\sin^2 p}$, $r = -\frac{2a \cos p}{\sin^2 p}$, $r^2 = \frac{\kappa}{A \cos^2 p + 2B \sin p \cos p + C \sin^2 p}$

If the equation $Ax^2 + 2Bxy + Cy^2 = \kappa$ takes the form $\frac{x^2}{a^2} + \frac{y^2}{b^2} = 1$,

or $\frac{x^2}{a^2} - \frac{y^2}{b^2} = 1$, the last polar equation becomes $r^2 = \frac{a^2 b^2}{a^2 \sin^2 p + b^2 \cos^2 p}$, or $r^2 = \frac{a^2 b^2}{b^2 \cos^2 p - a^2 \sin^2 p}$. Let us

suppose that a and b are positive, and that a is greater than b . The constant a will represent, in the parabolas, double the distance of the focus to the summit; in the ellipse half the greater or transverse axis; and in the hyperbola half the real or transverse axis. This understood, if we place the origin at the focus of the parabola, and if we

make $\frac{a}{2} = R$, the equation of the parabola in rectangular coordinates will take the form $y^2 = -4R(x - R)$, or

$x^2 + y^2 = (2R - x)^2$. And we shall conclude, if we observe that $R - x = \frac{y^2}{4R}$, that the quantity $R - x$, and

still more the quantity $2R - x$ must always remain positive. Hence $\sqrt{(x^2 + y^2)} = 2R - x$, or $x + \sqrt{(x^2 + y^2)} = 2R$. If now we substitute polar coordinates for the variables x and y we shall find for the polar equation of the parabola

$r + r \cos p = 2R$, or $r = \frac{2R}{1 + \cos p}$. When the same substitution is made in the equation $y^2 = -4R(x - R)$,

we find $r^2 = (2R - r \cos p)^2$, or $\{r(1 + \cos p) - 2R\} \{r(1 - \cos p) + 2R\} = 0$. Now, the quantities r and R being essentially positive, and the quantity $1 - \cos p$ being either positive or equal to nothing, it is clear that the factor $r(1 - \cos p) + 2R$ has always a finite value different from nothing. We may therefore suppress this factor, and by this means we find the same polar equation of the parabola as we had found before. In the ellipse, or the hyperbola, they give the name of *excentricity* to the ratio between the distance of a focus to the centre, and the half of the transverse axis or real axis. Let e be this ratio. The distance of the centre to one of the foci will be, for the ellipse, $ae = \sqrt{(a^2 - b^2)}$, and for the hyperbola $ae = \sqrt{(a^2 + b^2)}$. This understood, if we place the origin of coordinates, in the ellipse, at the focus situated on the side of the positive abscissæ, and in the hyperbola at the focus situated on the side of the negative abscissæ, the equations of these curves, in rectan-

gular coordinates, will present themselves under the form $\frac{(x + ae)^2}{a^2} + \frac{y^2}{b^2} = 1$, $\frac{(x - ae)^2}{a^2} - \frac{y^2}{b^2} = 1$, and if in

these equations we put for b its value derived from the equation $ae = \sqrt{(a^2 - b^2)}$, they will become respectively

$$y^2 = (1 - e^2) \{a^2 - (x + ae)^2\}, \quad y^2 = (e^2 - 1) \{(x - ae)^2 - a^2\}, \quad \text{or } x^2 + y^2 = \{a(1 - e^2) - ex\}^2, \\ \text{and } x^2 + y^2 = \{a(e^2 - 1) - ex\}^2.$$

Now, if in these last equations we substitute polar coordinates for rectangular coordinates, we shall find for the polar equation of the ellipse

$$\{r - a(1 - e^2) + er \cos p\} \{r + a(1 - e^2) - er \cos p\} = 0,$$

and for the polar equation of the hyperbola

$$\{r - a(e^2 - 1) + er \cos p\} \{r + a(e^2 - 1) - er \cos p\} = 0.$$

In the first equation $e = \sqrt{1 - \frac{b^2}{a^2}}$ being less than unity, the factor $r + a(1 - e^2) - er \cos p = r(1 - e \cos p) + a(1 - e^2)$ will have a positive value different from nothing. We may therefore suppress it, and reduce the

polar equation of the ellipse to the form $r(1 + e \cos p) - a(1 - e^2) = 0$, or $r = \frac{a(1 - e^2)}{1 + e \cos p}$. If in this last

equation we assume successively $p = 0$ and $p = \pi$, we shall have $r = a(1 - e)$ and $r = a(1 + e)$. These two values, the sum of which is $2a$, express the distances of the focus, taken for origin, to the two extremities of the transverse axis.

Integral
Calculus.

As to the equation of the hyperbola in which $\epsilon = \sqrt{1 + \frac{b^2}{a^2}}$ is evidently superior to one, it may be decomposed into two others, namely,

$$r(1 + \epsilon \cos p) - a(\epsilon^2 - 1) = 0, \text{ or } r = \frac{a(\epsilon^2 - 1)}{1 + \epsilon \cos p}, \text{ and } r(1 - \epsilon \cos p) + a(\epsilon^2 - 1) = 0, \text{ or } r = \frac{a(\epsilon^2 - 1)}{\epsilon \cos p - 1}.$$

Now, it is easy to verify that each of these equations represents only one of the two branches of the hyperbola; and that the equation from which we derive $r = a(\epsilon - 1)$ for $p = 0$, and $r = \infty$ for $p = \pm \cos^{-1} \frac{1}{\epsilon}$ belongs to the branch, the focus of which coincides with the origin, whilst the other equation from which we derive $r = a(\epsilon + 1)$ for $p = 0$, and $r = \infty$ for $p = \pm \cos^{-1} \frac{1}{\epsilon}$ belongs to the other branch. The two values of p , to

which correspond in each branch infinite values for r , indicate the directions of the two semi-axes which are the asymptots of that branch. As to the lengths $r = a(1 + \epsilon)$, $r = a(1 - \epsilon)$ the difference of which is equal to $2a$. They express the distances of the focus, taken for origin, to the two extremities of the real axis of the hyperbola.

(314.) Most of the preceding formulæ may be established in a direct manner, by geometrical considerations alone, in expressing by means of polar coordinates the known properties of the lines which these equations represent. Let us conceive, for instance, that P, R being the polar coordinates of a fixed point, and ψ any angle whatever positive or negative, it is required to find the polar equation of the straight line drawn through the point (P, R) parallelly to a semi-axis represented by the equation $p = \psi$. If, by the origin, we draw a radius vector r to any point whatever of the straight line, and if we call δ the acute or obtuse angle, which this radius vector, infinitely produced, makes with the semi-axis, the value of p corresponding to the radius vector under consideration will obviously be given by one of the four following formulæ, $p = \psi + \delta$, $p = \psi - \delta$, $p = \psi + \delta \pm 2n\pi$, $p = \psi - \delta \pm 2n\pi$, n being any integer whatever. It may be added that the first and third formulæ ought to be preferred, if a radius vector, turning round the axis, and setting off from the position in which it coincides with the semi-axis, is obliged to describe the angle δ to take a direct motion of rotation, whilst the second and fourth formulæ must be used in the contrary case. If now we project the radius vector r upon an axis perpendicular to the given straight line, we shall obtain for the projection the shortest distance from the origin to that straight line, and this shortest distance will be expressed by the product $r \sin \delta$, or $r \sin(p - \psi)$ or $r \sin(\psi - p)$. But the shortest distance just mentioned, being obviously a quantity independent of the variables r and p , we may conclude that the product $r \sin(p - \psi)$ or $r \sin(\psi - p)$ will not change when we replace in it p by P , and r by R . We shall have, therefore, $r \sin(p - \psi) = R \sin(P - \psi)$, or $r \sin(\psi - p) = R \sin(\psi - P)$. These formulæ are the same as those we have obtained before.

Let us try to find now the polar equation of the circle described from the point (P, R) as a centre with the radius ρ . If we call p, r the coordinates of any point of the circumference, and δ the angle contained between the radii r, R , we shall have $p = P \pm \delta$, or $p = P \pm \delta \pm 2n\pi$, and afterwards $\pm \delta = p - P \mp 2n\pi$, n being an integer, which may be supposed equal to nothing. Moreover, the angle δ being opposed to the radius ρ in the triangle, the sides of which are r, R and ρ , we shall have, by a well-known theorem of Trigonometry,

$$\cos \delta = \frac{R^2 + r^2 - \rho^2}{2Rr}.$$

If in this last formula we put for δ its values $p - P \mp 2n\pi$, we shall obtain the equation $\cos(p - P) = \frac{R + r^2 - \rho^2}{2Rr}$, which is the same as that obtained before.

Let us try now to find the polar equation of a parabola the summit of which coincides with the point (P, R) , and the focus with the origin. If we designate by p, r the coordinates of any point of the curve, and by δ the angle included between the radii r, R , we shall have still $\pm \delta = p - P \mp 2n\pi$. Moreover, the projection of the radius vector r on the axis of the parabola will have for its measure the numerical value of $r \cos \delta = r \cos(p - P)$, and as the distance of the focus to the directrix will be equal to $2R$, the distance of the point (p, r) to the directrix will obviously be equal to $2R - r \cos(p - P)$. But, according to a known property of the parabola, this distance ought also to be equal to the radius vector r . We shall have, therefore, $r = 2R - r \cos(p - P)$ or

$$r = \frac{2R}{1 + \cos(p - P)}.$$

To make this last equation coincide with the formula we have obtained before, it is sufficient to take for semi-polar axis that which, passing through the focus of the parabola, is directed towards the summit of that curve, and to make in consequence $P = 0$.

We might obtain with the same facility the equation of an ellipse, the focus of which would coincide with the origin, and one of the extremities of the transverse axis with the point (P, R) . For, let still p, r be the coordinates of any point of the curve, and δ the angle formed by the two radii R, r . Let a represent half the transverse axis, and ϵ the excentricity. In the triangle, the summits of which are the foci, and the point (p, r) of the curve, one of the sides, namely, the distance of the foci, will have for its measure the product of the transverse axis by the excentricity or the quantity $2a\epsilon$, and the two other sides, the sum of which, by a known property of the ellipse, is always equal to the transverse axis, will be represented by r and $2a - r$. In this triangle the angle opposed to the side $2a - r$ will be equal to δ , if the point (P, R) coincide with that extremity of the transverse axis which is most remote from the origin, and to the supplement of the angle δ , or to $\pi - \delta$ in the contrary case. If we adopt

Integral
Calculus.

Part III.

the second hypothesis, we shall find $\cos(\pi - \delta) = \frac{r^2 + (2a\epsilon)^2 - (2a - r)^2}{2(2a\epsilon)r} = \frac{1}{\epsilon} - \frac{a(1 - \epsilon^2)}{\epsilon r}$, or $r =$

$\frac{a(1 - \epsilon^2)}{1 + \epsilon \cos \delta}$; and then putting for δ its value derived from the equation $\pm \delta = p - P \mp 2n\pi$, we find

$r = \frac{a(1 - \epsilon^2)}{1 + \epsilon \cos(p - P)}$. This last equation contains with the angle P , two other constant quantities a, ϵ , one of

which might be replaced by the radius vector $R = a(1 - \epsilon)$. We may, moreover, remark that the last value we have obtained for r will become exactly the same as the value we have derived before from the equation of the ellipse in rectangular coordinates, if we take for semi-polar axis, that which passing through the origin of coordinates is directed towards the nearest extremity of the transverse axis, and if in consequence we make $P = 0$.

Let us consider lastly a branch of hyperbola, the focus of which is supposed to coincide with the origin, and the summit with the point (P, R) . Let p, r be the coordinates of any point of this branch, and δ the angle contained between the two radii r, R . Let $2a$ be the transverse or real axis of the hyperbola, and ϵ be the excentricity. In the triangle the summits of which are the foci, and the point (p, r) , one of the sides, namely, the distance of the foci, will be equal to the product $2a\epsilon$, and the two other sides, the difference of which is equal to $2a$, will be represented by r and $2a + r$. In this same triangle the angle opposed to the side $2a + r$ will be precisely the

angle δ . We shall have, therefore, $\cos \delta = \frac{r^2 + (2a\epsilon)^2 - (2a + r)^2}{2(2a\epsilon)r} = \frac{a(\epsilon^2 - 1)}{\epsilon r} - \frac{1}{\epsilon}$, or $r = \frac{a(\epsilon^2 - 1)}{1 + \epsilon \cos \delta}$,

and then putting for δ its value $\pm \delta = p - P \mp 2n\pi$, we shall have $r = \frac{a(\epsilon^2 - 1)}{1 + \epsilon \cos(p - P)}$. We might, in

this last equation, replace one of the constants a, ϵ by the radius $R = a(1 - \epsilon)$. We may moreover remark that if we take for semi-polar axis, that which, passing through the origin, is directed towards the summit of the branch we consider, and if accordingly we suppose $P = 0$, the last value we have obtained for r will become the same as that we have derived from the equation of the hyperbola referred to rectangular coordinates.

If the focus were placed, not at the focus of the branch of the hyperbola, the polar equation of which it is required to find, but at the focus of the other branch, it would obviously be necessary in the formula $r = \frac{a(\epsilon^2 - 1)}{1 + \epsilon \cos \delta}$ to

substitute for the length $2a + r$, the length $r - 2a$. We would have then $\cos \delta = \frac{r^2 + (2a\epsilon)^2 - (r - 2a)^2}{2(2a\epsilon)r}$

$= \frac{a(\epsilon^2 - 1)}{\epsilon r} + \frac{1}{\epsilon}$, or $r = \frac{a(\epsilon^2 - 1)}{\epsilon \cos \delta - 1}$, and, consequently, $r = \frac{a(\epsilon^2 - 1)}{\epsilon \cos(p - P) - 1}$. In supposing in this last

formula $P = 0$, we would find identically the result derived from the equation of the hyperbola in rectangular coordinates.

(315.) Polar coordinates may be used with advantage, not only to express, but also to discover the several properties of plane curves, and to determine their centres, their diameters, their singular points, &c. Let us suppose, for instance, that it is required to find the two axes, or the real axis of the ellipse or hyperbola represented

by the equation $r^2 = \frac{2\kappa}{A + C + 2B \sin 2p + (A - C) \cos 2p}$. For that purpose, it will obviously be sufficient

to double the maximum or minimum value of the radius vector r . It is clear, moreover, that this maximum or minimum value will correspond to a minimum or maximum of the expression $2B \sin 2p + (A - C) \cos 2p$, and

consequently, to a value of p determined by the formula $2B \cos 2p - (A - C) \sin 2p = 0$, or $\tan 2p = \frac{2B}{A - C}$,

which is obtained by making equal to nothing the differential coefficient of $2B \sin 2p + (A - C) \cos 2p$. Now the equation $\tan 2p = \frac{2B}{A - C}$ is satisfied by taking $p = \frac{1}{2} \tan^{-1} \frac{2B}{A - C} \pm n\pi$, or $p = \frac{1}{2} \tan^{-1} \frac{2B}{A - C} \pm$

$(n + \frac{1}{2})\pi$. These two last equations represent two straight lines at right angles to each other, which coincide with the axis of the curve under consideration.

From the formula $2B \cos 2p - (A - C) \sin 2p = 0$, we derive

$$\frac{\sin 2p}{2B} = \frac{\cos 2p}{A - C} = \pm \frac{1}{\sqrt{4B^2 + (A - C)^2}} = \frac{2B \sin 2p + (A - C) \cos 2p}{4B^2 + (A - C)^2},$$

and, consequently, we conclude that the maximum or minimum value of the expression $2B \sin 2p + (A - C) \cos 2p$ is $\pm \sqrt{4B^2 + (A - C)^2}$. We would arrive at the same conclusion in considering the equation

$$\{2B \sin 2p + (A - C) \cos 2p\}^2 + \{2B \cos 2p - (A - C) \sin 2p\}^2 = 4B^2 + (A - C)^2,$$

from which it results that the numerical value of the first quantity raised to the square, in the left side, is always inferior to the square root of the sum $4B^2 + (A - C)^2$, when the difference $2B \cos 2p - (A - C) \sin 2p$ has a value different from zero, and becomes equal to this square root, in the case where this same difference vanishes.

Integral
Calculus.

If now we substitute successively in the value of r the maximum and minimum values we have just found for a part of the denominator, we shall obtain the two equations Part III.

$$r^2 = \frac{\kappa}{A + C - \sqrt{\{4B^2 + (A - C)^2\}}}, \quad r^2 = \frac{\kappa}{A + C + \sqrt{\{4B^2 + (A - C)^2\}}}.$$

It is easy to see that these two values of r^2 are the two roots of the equation $\left(\frac{\kappa}{r^2} - A\right)\left(\frac{\kappa}{r^2} - C\right) = B^2$. Their

product, namely, $\frac{\kappa^2}{(AC - B^2)}$ has always the same sign as the difference $AC - B^2$, hence it is clear that they

will be both positive, if $AC - B^2$ being positive, A , C and K are quantities of the same sign. Then the maximum and minimum values of r^2 will give two real values maximum and minimum of r . On the contrary, one only of the values of r^2 will remain positive, and the corresponding value of r will alone be real if $AC - B^2$ become negative. We know, in fact, that the condition $AC - B^2 > 0$ is verified for the ellipse, and the condition $AC - B^2 < 0$ for the hyperbola, which has only one axis real.

(316.) Among the curves, the various properties of which may be more easily obtained by the use of polar coordinates than by the use of rectangular coordinates, we shall mention the curves named *spirals*, which generally form a great number, and even frequently an infinite number of revolutions round the centre, so as to approach more and more to the origin, or to become more and more distant from it. The spirals which have in particular been the object of the attention of geometers, are the *spiral of Archimedes*, the *hyperbolic spiral*, and the *logarithmic spiral*.

In the spiral of Archimedes, the radius vector r increases proportionally to the angle p . Therefore its polar equation is $r = ap$, a being a constant quantity. When this constant quantity is positive, only positive values must be taken for p , since r cannot be negative. In the same hypothesis, if we designate by R the value of r corresponding to $p = 2\pi$, we shall have $R = 2a\pi$, and if we make the angle p to increase from zero to infinity the radius vector r will vary between the same limits. Consequently the curve may be considered as described by a point which, setting off from the origin of coordinates, would turn an infinite number of times, with a direct motion, round that origin, and would get to an infinite distance from it. If in the equation $r = ap$, we

substitute for the constant a the radius vector R , this equation will become $r = \frac{Rp}{2\pi}$, and if we take R for the

unity of length we shall have simply $r = \frac{p}{2\pi}$.

(317.) The hyperbolic spiral is that curve the polar equation of which is obtained, in substituting the polar coordinates r and p in the place of the rectangular coordinates x and y in the equation $xy = a$, which represents an equilateral hyperbola referred to its asymptots. This spiral will, therefore, be represented by the formula

$rp = a$, or $r = \frac{a}{p}$. If we suppose that the constant a is positive, p must also be positive, and if we make p vary

between the limits zero and infinity, r will vary between the limits infinity and zero, so that we have $r = \frac{1}{0}$ for

$p = 0$, and $r = 0$ for $p = \frac{1}{0}$. Consequently the curve may be considered as described by a point which, setting

off from a position in which it would be placed at an infinite distance from the origin of coordinates, would make an infinite number of revolutions round the origin, with a direct motion, and would approach it indefinitely without ever reaching it, since r cannot be equal to nothing unless the number of revolutions is infinite. The hyperbolic spiral has for asymptot a straight line parallel to the axis of x , represented by the equation $y = a$. For, since

$y = r \sin p$, and $rp = a$, we have $y = \frac{a \sin p}{p}$, and, consequently, $y = a$ for $p = 0$, which value of p corresponds,

as it has already been remarked, with an infinite value for r .

(318.) The logarithmic spiral, sometimes called the *equiangular spiral*, is that in which the angle p is equal to the logarithm of the radius vector. If the basis of the logarithms is A , and if we have $Le = \frac{1}{lA} = a$, we shall

have for the polar equation of the logarithmic spiral $p = L(r) = alr$, or $r = e^{\frac{p}{a}}$. If $A > 1$, the constant a is positive. Then when p varies between the limits $-\frac{1}{0}$ and $+\frac{1}{0}$, r will remain positive, and will vary between the

limits $r = 0$ and $r = \infty$. It is also obvious that when $p = 0$, we have $r = 1$. This understood, we may clearly consider the logarithmic spiral as being described by a point, which being at first placed on the semi-polar axis, at a distance $= 1$ from the origin, would turn an infinite number of times round the origin, with a direct or retrograde motion, so as to become infinitely distant from the origin, in the first case, and to approach indefinitely the origin, in the second case, but without ever reaching it.

(319.) When a plane curve is represented by an equation in polar coordinates, to make it turn round the origin, in such a manner that each radius vector should describe an angle equal to P , it suffices to replace the coordinate p , by $p - P$, taking care to give to P a positive value when the motion of rotation is direct, and a negative value,

Integral
Calculus.

Part III.

in the contrary case. Operating in this manner on the equation $r = e^{\frac{p}{a}}$, we shall obtain the formula $r = e^{\frac{p-p}{a}}$, which will represent the logarithmic spiral in a new position. If then we call R the radius vector corresponding

to $p = 0$, we shall have $R = e^{\frac{-p}{a}}$, and the preceding equation becomes $r = R e^{\frac{p}{a}}$, or $p = a(lr - lR)$. If, in this last equation, we substitute for the coordinates r and p their values in x and y derived from the equations

$$x = r \cos p, \quad y = r \sin p, \quad \text{which are } p = \tan^{-1} \frac{y}{x}, \quad r = \sqrt{(x^2 + y^2)}, \quad \text{we shall find } \tan^{-1} \frac{y}{x} = a(l\sqrt{(x^2 + y^2)} - lR),$$

which is the equation of the logarithmic spiral referred to rectangular coordinates.

(320.) Polar coordinates may easily be introduced in the formulæ, which determine the direction of the tangent, the arc, or the radius of curvature of a plane curve.

We have found, ψ being the angle which the tangent at the point (x, y) makes with the semi-axis of positive abscissæ, $\tan \psi = \frac{dy}{dx}$. Now, since we have $x = r \cos p$, $y = r \sin p$, we shall find

$$\tan \psi = \frac{\sin p \, dr + r \cos p \, dp}{\cos p \, dr - r \sin p \, dp} = \frac{\tan p + \frac{r \, dp}{dr}}{1 - \tan p \frac{r \, dp}{dr}},$$

which formula gives

$$\frac{r \, dp}{dr} = \frac{\tan \psi - \tan p}{1 + \tan \psi \tan p} = \tan(\psi - p) \text{ or } \cot(\psi - p) = \frac{dr}{r \, dp}.$$

This last formula may easily be obtained in a direct manner. We have $\frac{\cos p}{x} = \frac{\sin p}{y}$, $\frac{\cos \psi}{dx} = \frac{\sin \psi}{dy}$, and, consequently,

$$\cot(\psi - p) = \frac{\cos(\psi - p)}{\sin(\psi - p)} = \frac{\cos p \cos \psi + \sin p \sin \psi}{\cos p \sin \psi - \sin p \cos \psi} = \frac{x \, dy + y \, dx}{x \, dy - y \, dx}.$$

But we have $r^2 = x^2 + y^2$, $p = \tan^{-1} \frac{y}{x}$, consequently $2r \, dr = 2x \, dx + 2y \, dy$, $dp = \frac{x \, dy - y \, dx}{x^2 + y^2} = \frac{x \, dy - y \, dx}{r^2}$,

or, which is the same thing, $x \, dx + y \, dy = r \, dr$, $r^2 \, dp = x \, dy - y \, dx$, and hence $\cot(\psi - p) = \frac{r \, dr}{r^2 \, dp} = \frac{dr}{r \, dp}$.

We might also obtain very easily this formula by the following considerations. We have found that $r \sin(p - \psi) = R \sin(P - \psi) = a$ constant quantity, was the polar equation of a straight line. In order that this line should be tangent to a plane curve, at a given point, it will be necessary that the values of the quantities

$p, r, \frac{dr}{dp}$ corresponding to that point should remain the same in passing from the straight line to the curve. But

by differentiating the equation of the straight line, we find $\sin(p - \psi) \, dr + \cos(p - \psi) \, r \, dp = 0$, which gives for $\cot(\psi - p)$ the same value we have found above.

(321.) By means of these formulæ, it is now easy to find the equations of the tangent and normal drawn to a given curve through a given point. Let us conceive, for instance, that p, r are the coordinates of the point of contact, and P, R the variable coordinates of the tangent. The polar equation of that line will be $R \sin$

$(P - \psi) = r \sin(p - \psi)$, the angle ψ being determined by the equation $\cot(\psi - p) = \frac{dr}{r \, dp}$. But the equation

$R \sin(P - \psi) = r \sin(p - \psi)$ may be written in the following manner; $\frac{R \cos(P - p) - r}{R \sin(P - p)} = \cot(\psi - p)$, and

therefore the polar equation of the tangent will be $\frac{R \cos(P - p) - r}{R \sin(P - p)} = \frac{dr}{r \, dp}$. To obtain the equation of the

normal, it will be sufficient to substitute $\psi \pm \frac{\pi}{2}$ to ψ . Hence we shall have, P and R being the variable coordi-

nates of the normal, $\frac{R \cos(P - p) - r}{R \sin(P - p)} = -\tan(\psi - p) = -\frac{r \, dp}{dr}$, for the equation of that line.

(322.) Let now v be the angle formed by the curve with the circle described from the origin as a centre with a radius r , that is to say the acute angle formed by the tangent with the perpendicular to this radius, $\frac{\pi}{2} - v$ will be the acute angle, which this same radius forms with the tangent, and consequently the least of the numerical values of $\psi - p$. Therefore, we shall have $\tan v = \cot\left(\frac{\pi}{2} - v\right) = \pm \cot(\psi - p)$, and afterwards $\tan v = \pm \frac{dr}{r \, dp}$

$= \pm \frac{dlr}{dp}$. Moreover, as the quantity $\tan v$ will be essentially positive, and as for very small numerical values of

Integral
Calculus.

Δp , the ratio $\frac{\Delta r}{\Delta p}$ will always have the same sign as its limit $\frac{dr}{dp}$, we shall take the sign + in the value of $\tan v$, if, setting off from the point (p, r) , the radius r increases with the angle p , and the sign - in the contrary case.

We shall for the sake of brevity suppose $\frac{dr}{dp} = r$, then the preceding value of $\tan v$ becomes $\pm \frac{r'}{r}$, and, consequently, we have

$$\cos v = \pm \frac{r}{\sqrt{(r^2 + r'^2)}}, \quad \sin v = \frac{r'}{\sqrt{(r^2 + r'^2)}}.$$

Let s represent the arc of a given curve reckoned from a fixed point on the curve, and let ρ be the radius of curvature. We have found $ds^2 = dx^2 + dy^2$, $\frac{1}{\rho} = \pm \frac{dx \, d^2y - dy \, d^2x}{(dx^2 + dy^2)^{\frac{3}{2}}}$. If we substitute in these formulæ the

values of x, y, dx, dy , &c. derived from the equations $x = r \cos p, y = r \sin p$, we shall have, after reduction, $ds^2 = dr^2 + r^2 dp^2$, $\frac{1}{\rho} = \pm \frac{r(dr \, d^2p - dp \, d^2r) + (2dr^2 + r^2 dp^2) dp}{(dr^2 + r^2 dp^2)^{\frac{3}{2}}}$, and, consequently, taking p for the

independent variable,

$$\frac{ds^2}{dp^2} = r^2 + r'^2, \quad \frac{1}{\rho} = \pm \frac{r^2 - r r'' + 2r'^2}{(r^2 + r'^2)^{\frac{3}{2}}},$$

where $r'' = \frac{d^2r}{dp^2}$. It is essential to remark that in using, instead of the equations $x = r \cos p, y = r \sin p$, the formulæ $x + y\sqrt{-1} = r e^{p\sqrt{-1}}, x - y\sqrt{-1} = r e^{-p\sqrt{-1}}$, which are equivalent to them, the calculation is much shortened, and there is no reduction to make. Thus, for instance, if we take x for the independent variable, we shall have

$$dx + dy\sqrt{-1} = (r' + r\sqrt{-1}) e^{p\sqrt{-1}} dp, \quad dx - dy\sqrt{-1} = (r' - r\sqrt{-1}) e^{-p\sqrt{-1}} dp,$$

$$d^2x + d^2y\sqrt{-1} = (r'' - r + 2r'\sqrt{-1}) e^{p\sqrt{-1}} dp^2, \quad d^2x - d^2y\sqrt{-1} = (r'' - r - 2r'\sqrt{-1}) e^{-p\sqrt{-1}} dp^2,$$

Now, if we multiply the two first equations, and then the second and third, we find immediately $dx^2 + dy^2 = (r^2 + r'^2) dp^2$, and we find also that $dx \, d^2y - dy \, d^2x$ is equal to the coefficient of $\sqrt{-1}$ in the product $(r' - r\sqrt{-1})(r'' - r + 2r'\sqrt{-1}) dp^3$, so that we have $dx \, d^2y - dy \, d^2x = (2r'^2 - r r'' + r^2) dp^3$. If we did not take p for the independent variable, we would have found

$$dx^2 + dy^2 = dr^2 + r^2 dp^2, \quad dx \, d^2y - dy \, d^2x = r(dr \, d^2p - dp \, d^2r) + (2dr^2 + r^2 dp^2) dp.$$

(323.) Let now x_1, y_1 be the rectangular coordinates of the centre of curvature corresponding to the point x, y , and P, R the polar coordinates of the same centre, so that $x_1 = R \cos P, y_1 = R \sin P$. We have found (306.)

$$\frac{y_1 - y}{dx} = -\frac{x_1 - x}{dy} = \frac{dx^2 + dy^2}{dx \, d^2y - dy \, d^2x},$$

from which we easily derive

$$\frac{y(y_1 - y) + x(x_1 - x)}{y \, dx - x \, dy} = \frac{x(y_1 - y) - y(x_1 - x)}{x \, dx + y \, dy} = \frac{dx^2 + dy^2}{dx \, d^2y - dy \, d^2x}$$

or, which is the same thing,

$$\frac{xx_1 + yy_1 - (x^2 + y^2)}{y \, dx - x \, dy} = \frac{xy_1 - yx_1}{x \, dx + y \, dy} = \frac{dx^2 + dy^2}{dx \, d^2y - dy \, d^2x}.$$

If then we substitute polar coordinates for rectangular coordinates by means of the formulæ we have already found, we shall have

$$\frac{R \cos(P - p) - r}{-r \, dp} = \frac{R \sin(P - p)}{dr} = \frac{dr^2 + r^2 dp^2}{r(dr \, d^2p - dp \, d^2r) + (2dr^2 + r^2 dp^2) dp}.$$

If we take p for the independent variable, we shall have simply,

$$1 - \frac{R}{r} \cos(P - p) = \frac{R}{r'} \sin(P - p) = \frac{r^2 + r'^2}{2r'^2 - r r'' + r^2}.$$

From this last formula, we derive

$$R \sin(P - p) = r' \frac{r^2 + r'^2}{2r'^2 - r r'' + r^2}, \quad R \cos(P - p) = r \left(1 - \frac{r^2 + r'^2}{2r'^2 - r r'' + r^2} \right) = r \frac{r'^2 - r r''}{2r'^2 - r r'' + r^2}$$

and, consequently,

$$\tan(P - p) = \frac{r'}{r} \frac{r^2 + r'^2}{r'^2 - r r''}, \quad R^2 = \frac{r'^2 (r^2 + r'^2)^2 + r^2 (r'^2 - r r'')^2}{(2r'^2 - r r'' + r^2)^2}.$$

It is useful to remark, that since $\frac{1}{\rho} = \pm \frac{r^2 - r r'' + 2r'^2}{(r^2 + r'^2)^{\frac{3}{2}}}$, we shall have

$$1 - \frac{R}{r} \cos (P - p) = \frac{R}{r} \sin (P - p) = \pm \frac{\rho}{\sqrt{(r^2 + r'^2)}},$$

and, consequently,

$$R \sin (P - p) = \pm \frac{r'}{\sqrt{(r^2 + r'^2)}} \rho = \pm \rho \sin v, \quad R \cos (P - p) - r = \mp \frac{r}{\sqrt{(r^2 + r'^2)}} \rho = \mp \rho \cos v.$$

(324.) These last formulæ may be obtained in a different manner. The circle described from the point (P, R) as a centre with a radius equal to ρ has for polar equation $r^2 - 2 R r \cos (P - p) + R^2 = \rho^2$. Now, let us suppose that this circle becomes the osculating circle of a given curve, in a certain point given on the curve. Not only the coordinates p and r but also the differentials dp, dr, d^2p, d^2r , corresponding to the coordinates of the point of contact ought to preserve the same values in passing from the circle to the curve. In other words, the value of p, dp, d^2p, r, dr, d^2r derived from the equations of the curve, must satisfy the equation of the circle, and its two differential equations of the first and second order. These three last equations may be written as follows:

$$\{R \sin (p - P)\}^2 + \{R \cos (p - P) - r\}^2 = \rho^2, \quad R r \sin (p - P) dp - \{R \cos (p - P) - r\} dr = 0,$$

$$R \sin (p - P) \{r d^2p + 2 dp dr\} - \{R \cos (p - P) - r\} (d^2r - r dp^2) = -(dr^2 + r^2 dp^2).$$

From which we immediately derive the formula

$$\begin{aligned} \frac{R \cos (p - P) - r}{r dp} &= \frac{R \sin (p - P)}{dr} = \pm \frac{\{[R \sin (p - P)]^2 + [R \cos (p - P) - r]^2\}^{\frac{1}{2}}}{\sqrt{(dr^2 + r^2 dp^2)}} = \pm \frac{\rho}{\sqrt{(dr^2 + r^2 dp^2)}} \\ &= \frac{R \sin (p - P) \cdot (r d^2p + 2 dp dr) - \{R \cos (p - P) - r\} (d^2r - r dp^2)}{r (dr d^2p - dp d^2r) + 2 (dr^2 + r^2 dp^2) dp} \\ &= \frac{dr^2 + r^2 dp^2}{r (dr d^2p - dp d^2r) + (2 dr^2 + r^2 dp^2) dp}. \end{aligned}$$

(325.) Most of the preceding formulæ may be established by Geometrical considerations alone.

Let us consider two points of a plane curve very near each other. Let p, r , and $p + \Delta p, r + \Delta r$ be the coordinates of these two points. Let s , as usual, be the length of the arc of the curve between the point (p, r) and a fixed point, and let v the acute angle formed by the curve, and the circle described from the origin as a centre, with a radius equal to r . The arcs of the curve and circle between the radii r and $r + \Delta r$, will be respectively Δs and $r \Delta p$. If we call ω the acute angle formed by the chords of these arcs, the limit of ω will be precisely v . The two chords and the length $\pm \Delta r$ will form a right angled triangle in which the side $\pm \Delta r$ will be opposed to the angle ω . In this same triangle, when the arc $\pm \Delta s$ will become infinitely small, the angle opposed to the chord of this arc will differ very little from a right angle, and may be represented consequently by $\frac{\pi}{2} \pm \epsilon$, $\pm \epsilon$ being a very small quantity. Hence, the third angle, opposed to the chord of the arc $\pm r \Delta p$, will be $\frac{\pi}{2} - \omega \mp \epsilon$, and if we compare two and two the sines of the angles to the sides opposed to them, we shall have

$$\pm \frac{\Delta r}{\Delta s} = \frac{\sin \omega}{\sin \left(\frac{\pi}{2} \pm \epsilon \right)}, \quad \pm \frac{r \Delta p}{\Delta s} = \frac{\sin \left(\frac{\pi}{2} - \omega \mp \epsilon \right)}{\sin \left(\frac{\pi}{2} \pm \epsilon \right)},$$

from which we shall derive, in substituting first $\cos (\omega \pm \epsilon)$ for $\sin \left(\frac{\pi}{2} - \omega \mp \epsilon \right)$, and then taking the limits,

$$\pm \frac{dr}{ds} = \sin v, \quad \pm \frac{r dp}{ds} = \cos v. \quad \text{If we divide the first of these equations by the second, we find as before,}$$

$$\tan v = \frac{dr}{r dp}; \quad \text{if we add them after having raised to the square both sides of each, we shall obtain the formula}$$

$$\frac{dr^2 + r^2 dp^2}{ds^2} = 1.$$

(326.) Let us consider now the triangle which has for its summits the origin of coordinates, the point (p, r) of the plane curve, and the centre of curvature corresponding to that point. If we call ρ the radius of curvature, and (P, R) the coordinates of the centre of curvature, the three sides of the triangle will be respectively r, R , and ρ . In the same triangle, the acute angle formed by r and ρ will clearly be equal to v , which is the angle between the tangent and the perpendicular to the radius vector, or to the supplement of that angle. If we call δ the angle formed by the radii r and R , we shall have clearly $\pm \delta = p - P \pm 2n\pi$, n being an integer, which may be equal to nothing. As to the third angle, its supplement will be the sum of the other two, that is $\delta + v$, or $\delta + \pi - v$.

This understood, if we compare the sines of the angles to the sides, we find $\frac{\sin v}{R} = \frac{\sin \delta}{\rho} = \frac{\sin v \pm \delta}{r}$. Hence,

$$R \sin \delta = \rho \sin v, \quad R \cos \delta - r = \mp \rho \cos v. \quad \text{If in these last formulæ we put for } \delta \text{ its value } p - P \pm 2n\pi, \text{ we shall find again the formulæ } R \sin (P - p) = \pm \rho \sin v, \quad R \cos (P - p) - r = \mp \rho \cos v.$$

(327.) We shall now show some applications of the general formulæ that have been demonstrated.

Integral
Calculus.

If, first, we consider the spiral of Archimedes represented by the equation $r = ap$, we shall have $r' = a$, $r'' = 0$, Part III.
and consequently, a being a positive quantity,

$$\tan v = \cot(\psi - p) = \frac{1}{p}, \quad \frac{1}{\rho} = \frac{2 + p^2}{(1 + p^2)^{\frac{3}{2}}} \cdot \frac{1}{a} = \left(1 + \frac{1}{1 + p^2}\right) \frac{1}{a \sqrt{1 + p^2}}.$$

At the same time the general values of $\tan(P - p)$ and R^2 given (321.) will become

$$\tan(P - p) = p + \frac{1}{p}, \quad R^2 = a^2 \frac{2p^2 + (1 + p)^2}{(2 + p^2)^2} = a^2 \left\{1 - \frac{1}{2 + p^2} - \frac{1}{(2 + p^2)^2}\right\}.$$

Hence for $p = 0$, we shall have $\tan v = \cot \psi = \tan P = \frac{1}{0}$, $v = \frac{\pi}{2}$, $\rho = R = \frac{a}{2}$; and for $p = \frac{1}{0}$, $\tan v = 0$,

$v = 0$, $\tan(P - p) = \frac{1}{0}$, $\frac{1}{\rho} = 0$, $R = a$. Consequently, 1. the spiral touches at the origin of coordinates the

polar axis; 2. for increasing values of p , the angle v , and the curvature $\frac{1}{\rho}$ decrease indefinitely in this same spiral,

whilst the value of R increases indefinitely, but in such manner as to be contained between the limits $\frac{a}{2}$ and a ;

3. for very large values of p , the radius R , drawn from the origin to the centre of curvature, becomes nearly equal to a , and very nearly also perpendicular to the radius r . If in the above value of $\tan(P - p)$, we substitute for p the real and positive value derived from the equation expressing the value of R , or which is the same thing, from

the equation $\frac{1}{2 + p^2} = \frac{1 \pm \sqrt{5 - \frac{4R^2}{a^2}}}{2}$, we shall find for the polar equation of the evolute of the spiral,

$$\tan \left\{ P - \frac{\left[\sqrt{\left(5 - \frac{4R^2}{a^2}\right)} - 3 + \frac{4R^2}{a^2} \right]^{\frac{1}{2}}}{2^{\frac{1}{2}} \left(1 - \frac{R^2}{a^2}\right)^{\frac{1}{2}}} \right\} = \frac{\frac{2R^2}{a^2} - 1 + \sqrt{\left(5 - \frac{4R^2}{a^2}\right)}}{2^{\frac{1}{2}} \left(1 - \frac{R^2}{a^2}\right)^{\frac{1}{2}} \left[\sqrt{\left(5 - \frac{4R^2}{a^2}\right)} - 3 + \frac{4R^2}{a^2} \right]^{\frac{1}{2}}}.$$

This evolute is clearly a new spiral which presents a *stop* point corresponding to the coordinates $R = \frac{a}{2}$, $P = \frac{\pi}{2}$;

it is perpendicular at that point to the circle described from the origin as a centre with the radius $\frac{a}{2}$, and which as it removes from this circle, makes an infinite number of revolutions round the origin, so as to approach more and more to the circumference of another circle, having the same centre as the first, and described with a radius twice as great. As this new spiral and this circumference will never meet, one of them may be said to be an asymptote of the other.

If instead of the spiral of Archimedes we consider the spiral represented by the equation $r = ap^n$, we find $r' = nap^{n-1} = \frac{nr}{p}$, $r'' = n(n-1)ap^{n-2} = \frac{n(n-1)r}{p^2}$, and, consequently, $\tan v = \cot(\psi - p) = \frac{n}{p}$,

$$\frac{1}{\rho} = \frac{n(n+1) + p^2}{(n^2 + p^2)^{\frac{3}{2}}} \cdot \frac{1}{ap^{n-1}}, \quad \tan(P - p) = p + \frac{n^2}{p},$$

$$R^2 = \frac{p^2 + (n^2 + p^2)^2 n^2 a^2 p^{2n-2}}{(n(n+1) + p^2)^2}.$$

If in the preceding formulæ, we suppose that the constant n is positive, we shall find again for $p = 0$, $\tan v = \cot \psi = \frac{1}{0}$, $v = \frac{\pi}{2}$, and for $p = \frac{1}{0}$, $\tan v = 0$, $v = 0$, $\tan(P - p) = \frac{1}{0}$. Hence we shall infer that the curve touches at the origin the polar axis, and becomes for large values of p very nearly perpendicular to the radius vector r . In the same hypothesis, the values of ρ and R corresponding to $p = 0$, or $p = \frac{1}{0}$, will be as this angle nothing or infinite unless we suppose $n = 1$, that is to say, unless the curve becomes the spiral of Archimedes.

Let us consider next the hyperbolic spiral represented by the equation $rp = a$. We shall find $r' = -\frac{a}{p^2}$, $r'' = \frac{2a}{p^3}$, and supposing that the constant a is a positive quantity, we shall have $\tan v = \cot(\psi - p) = \frac{1}{p}$,

$$\frac{1}{\rho} = -\frac{p^2}{(1 + p^2)^{\frac{3}{2}}} \cdot \frac{1}{a}, \quad \tan(P - p) = p + \frac{1}{p}, \quad R^2 = \left\{ \frac{1}{p^2} + \left(1 + \frac{1}{p^2}\right)^2 \right\} \frac{a^2}{p^4}.$$

Then, for $p = 0$, we have $\tan v = \cot \psi = \tan P = \frac{1}{0}$, $v = \frac{\pi}{2}$, $\rho = R = \frac{1}{0}$, and for $p = \frac{1}{0}$, $\tan v = 0$, $v = 0$, $\tan(P - p) = \frac{1}{0}$, $\rho = R = 0$.

Integral
Calculus.

Part III.

These results show, 1. that the angle v is nearly a right angle and the curvature very nearly nothing, for very small values of p , that is to say in that part of the hyperbolic spiral which is very remote from the origin, and which nearly coincides with the asymptote of that curve; 2. that for increasing values of the angle p , the angle

v decreases from $v = \frac{\pi}{2}$ to $v = 0$, and that the same thing may be said with respect to the radius of curvature ρ ,

and the radius vector R , the values of which, at first very large, at last become equal to nothing.

It is clear that by eliminating p between the value of $\tan(P-p)$ and that of R^2 we shall find the polar equation of the evolute of the hyperbolic spiral. It will show that this evolute is a spiral, which possesses also the remarkable property of approaching indefinitely to the centre without ever reaching it.

Lastly, let us consider the logarithmic spiral represented by the equation $r = e^{\frac{p}{a}}$. We shall find $r' = \frac{r}{a}$, $r'' = \frac{r}{a^2}$,

$\tan v = \cot(\psi - p) = \frac{1}{a} \rho = \left(1 + \frac{1}{a^2}\right)^{\frac{1}{2}} e^{\frac{p}{a}} = \left(1 + \frac{1}{a^2}\right)^{\frac{1}{2}} r = r \sec v$. The value of $\tan v$ shows that the

tangent and the normal form constantly the same angles with the radius vector r , which remark gives the means to draw the tangents and normals to the curve through a given point.

We have also in this case, $R \sin(P-p) = r' = \frac{r}{a}$, $R \cos(P-p) = 0$, and, consequently, $\cos(P-p) = 0$, $\sin(P-p) = 1$,

$R = \frac{r}{a}$. The smallest value of P which verifies these equations being $P = p + \frac{\pi}{2}$, it may be affirmed, that the

radii r , R of the curve and its evolute meet at right angles, or, in other words, that r and R are the two sides of a right angled triangle, the hypotenuse of which is the radius of curvature. If we eliminate p between the

equations $r = e^{\frac{p}{a}}$, $R = \frac{r}{a}$, and $P = p + \frac{\pi}{2}$, we shall find for the polar equation of the evolute, $R = \frac{1}{a} e^{\frac{1}{a}(P - \frac{\pi}{2})}$

$= e^{\frac{1}{a}(P - \frac{\pi}{2} - a \log a)}$. In substituting in this last formula r for R , and $p + \frac{\pi}{2} + a \log a$ for P , we would find for result the

equation $r = e^{\frac{p}{a}}$. Hence 1. the logarithmic spiral and its evolute are two curves having the same form and dimensions; 2. to obtain the evolute it is sufficient to make the involute turn round the origin, so as to make each

radius vector describe, by a direct motion of rotation, an angle equal to $\frac{\pi}{2} + a \log a$.

On Curves represented by two Equations between three Variables.

(328.) We shall now consider any curve whatever represented by two equations between three rectangular coordinates x, y, z . The results which we shall obtain will therefore be applicable to any curve, whether it be a plane curve, or a curve of double curvature, that is a curve which is not all in the same plane.

Let us represent the coordinates of any point of that curve by x, y, z , and by $x+h, y+\kappa, z+l$, the coordinates of another point belonging to the same curve. Then, if we join these two points, and if we designate by a, b, c , the angles which the line of junction makes respectively with the three axes, x, y, z , we shall have (See ANALYTICAL GEOMETRY)

$$\cos a = \frac{h}{\sqrt{h^2 + \kappa^2 + l^2}}, \quad \cos b = \frac{\kappa}{\sqrt{h^2 + \kappa^2 + l^2}}, \quad \cos c = \frac{l}{\sqrt{h^2 + \kappa^2 + l^2}},$$

and hence $\frac{\cos a}{h} = \frac{\cos b}{\kappa} = \frac{\cos c}{l}$. If, besides, we represent by x_1, y_1, z_1 , the coordinates of any point of the chord under consideration, it is easy to see that we shall have also

$$\frac{x_1 - x}{\cos a} = \frac{y_1 - y}{\cos b} = \frac{z_1 - z}{\cos c}, \quad \text{and, consequently,} \quad \frac{x_1 - x}{h} = \frac{y_1 - y}{\kappa} = \frac{z_1 - z}{l}.$$

Let us now imagine that the point the coordinates of which are $x+h, y+\kappa, z+l$, approaches nearer and nearer, and indefinitely to the point the coordinates of which are x, y, z . The secant which joins the two points will, at the same time, approach nearer and nearer to coincide with a certain line which is called a *tangent* to the given curve, and which touches it at the point (x, y, z) . To obtain the angles α, β, γ , which the producement of this tangent makes with the three axes x, y, z , it will be sufficient to find the limits towards which the angles a, b, c converge

whilst the quantities h, κ, l become less and less, and infinitely small quantities. But at the limit the ratios $\frac{\kappa}{h}, \frac{l}{h}$,

become equal to the quantities $\frac{dy}{dx}, \frac{dz}{dx}$, therefore

$$\cos \alpha = \frac{dx}{\sqrt{(dx)^2 + (dy)^2 + (dz)^2}}, \quad \cos \beta = \frac{dy}{\sqrt{(dx)^2 + (dy)^2 + (dz)^2}}, \quad \cos \gamma = \frac{dz}{\sqrt{(dx)^2 + (dy)^2 + (dz)^2}},$$

Integral
Calculus.

Part III.

and hence $\frac{\cos \alpha}{dx} = \frac{\cos \beta}{dy} = \frac{\cos \gamma}{dz}$. If, moreover, we designate by x_1, y_1, z_1 , the coordinates of any point of the tangent, we have

$$\frac{x_1 - x}{\cos \alpha} = \frac{y_1 - y}{\cos \beta} = \frac{z_1 - z}{\cos \gamma}, \text{ and therefore } \frac{x_1 - x}{dx} = \frac{y_1 - y}{dy} = \frac{z_1 - z}{dz}.$$

These equalities are verified for any point of the tangent; they are true even in case the axis of coordinates should be oblique, and when these axes are rectangular they are the equations of the projections of the tangent upon the three coordinate planes. They are also true whatever be the independent variable.

(329.) A plane is said to be tangent to a curve in a given point, when it passes through the tangent at that point. Hence it is obvious that through a given point, on a given curve, an infinite number of tangent planes may be drawn.

(330.) A straight line is said to be normal to a curve in a given point, when it is perpendicular to the tangent at that point. Hence it is obvious that through a given point it will be possible to draw an infinite number of normals to a curve. All these normals will be situated in a plane perpendicular to the tangent, and this plane is called a normal plane to the curve. If we represent still by α, β, γ , the angles which the tangent to the curve makes with the coordinate axes, and by x_1, y_1, z_1 , the coordinates of any point of the normal plane, it will clearly follow from what precedes that the equation of the normal plane will be

$$(x_1 - x) \cos \alpha + (y_1 - y) \cos \beta + (z_1 - z) \cos \gamma = 0,$$

or by using the relations we have found between $\cos \alpha, \cos \beta, \cos \gamma$, and dx, dy, dz ,

$$(x_1 - x) dx + (y_1 - y) dy + (z_1 - z) dz = 0,$$

a result which is true whatever be the independent variable.

(331.) Let now $u = 0, v = 0$ be the two equations of the given curve, that is the equations of two surfaces which contain it, so that u and v designate two functions of three variables. We shall have by differentiation

$$\frac{du}{dx} dx + \frac{du}{dy} dy + \frac{du}{dz} dz = 0, \quad \frac{dv}{dx} dx + \frac{dv}{dy} dy + \frac{dv}{dz} dz = 0,$$

and consequently since $\frac{\cos \alpha}{dx} = \frac{\cos \beta}{dy} = \frac{\cos \gamma}{dz}$, we find

$$\frac{du}{dz} \cos \alpha + \frac{du}{dy} \cos \beta + \frac{du}{dx} \cos \gamma = 0, \quad \frac{dv}{dx} \cos \alpha + \frac{dv}{dy} \cos \beta + \frac{dv}{dz} \cos \gamma = 0.$$

These two last equations, together with the equation $\cos^2 \alpha + \cos^2 \beta + \cos^2 \gamma = 1$ will be sufficient to determine the values of $\cos \alpha, \cos \beta$, and $\cos \gamma$. We shall find

$$\begin{aligned} \frac{\cos \alpha}{\frac{du}{dy} \cdot \frac{dv}{dz} - \frac{du}{dz} \cdot \frac{dv}{dy}} &= \frac{\cos \beta}{\frac{du}{dz} \cdot \frac{dv}{dx} - \frac{du}{dx} \cdot \frac{dv}{dz}} = \frac{\cos \gamma}{\frac{du}{dx} \cdot \frac{dv}{dy} - \frac{du}{dy} \cdot \frac{dv}{dx}} = \\ &= \pm \frac{1}{\left[\left(\frac{du}{dy} \cdot \frac{dv}{dz} - \frac{du}{dz} \cdot \frac{dv}{dy} \right)^2 + \left(\frac{du}{dz} \cdot \frac{dv}{dx} - \frac{du}{dx} \cdot \frac{dv}{dz} \right)^2 + \left(\frac{du}{dx} \cdot \frac{dv}{dy} - \frac{du}{dy} \cdot \frac{dv}{dx} \right)^2 \right]}. \end{aligned}$$

These values being substituted, will give for the equations of the tangent, and of the normal plane,

$$\begin{aligned} \frac{x_1 - x}{\frac{du}{dy} \cdot \frac{dv}{dz} - \frac{du}{dz} \cdot \frac{dv}{dy}} &= \frac{y_1 - y}{\frac{du}{dz} \cdot \frac{dv}{dx} - \frac{du}{dx} \cdot \frac{dv}{dz}} = \frac{z_1 - z}{\frac{du}{dx} \cdot \frac{dv}{dy} - \frac{du}{dy} \cdot \frac{dv}{dx}}, \text{ and} \\ \left(\frac{du}{dy} \cdot \frac{dv}{dz} - \frac{du}{dz} \cdot \frac{dv}{dy} \right) (x_1 - x) &+ \left(\frac{du}{dz} \cdot \frac{dv}{dx} - \frac{du}{dx} \cdot \frac{dv}{dz} \right) (y_1 - y) + \left(\frac{du}{dx} \cdot \frac{dv}{dy} - \frac{du}{dy} \cdot \frac{dv}{dx} \right) (z_1 - z) = 0. \end{aligned}$$

Moreover it may be observed that instead of the equations of the projections of the tangent upon the coordinate planes, we may use to represent this line the two following equations,

$$(x_1 - x) \frac{du}{dx} + (y_1 - y) \frac{du}{dy} + (z_1 - z) \frac{du}{dz} = 0, \quad (x_1 - x) \frac{dv}{dx} + (y_1 - y) \frac{dv}{dy} + (z_1 - z) \frac{dv}{dz} = 0. \dots (a).$$

These are immediately obtained by combining the differential equations of the two surfaces with the relations

$$\frac{x_1 - x}{dx} = \frac{y_1 - y}{dy} = \frac{z_1 - z}{dz}, \text{ which have been obtained above, and they represent two planes the intersection of}$$

which is the tangent to the curve. By comparing them with the differential equations of the curve, we find that in order to obtain the equations of the tangent to any curve whatever, it is sufficient to substitute, in the differential equations of the curve, $x_1 - x, y_1 - y, z_1 - z$, for dx, dy , and dz .

Integral
Calculus.

 (332.) When u is a function of x and y only, the first of the two last equations is reduced to $(x_1 - x) \frac{du}{dx} +$ Part III.

$(y_1 - y) \frac{du}{dy} = 0$. In that case $u = 0$ is the equation of the projection of the curve on the plane of the x, y , and the equation $(x_1 - x) \frac{du}{dx} + (y_1 - y) \frac{du}{dy} = 0$ is, at the same time, the equation of the projection of the tangent to the curve in space on the same plane, and the equation of the tangent to the projection of the curve. Hence it appears that the projection of the tangent to any curve whatever, upon a given plane, coincides with the tangent to the projection of the curve on the same plane.

(333.) We shall now give a few applications of the preceding formulæ. Let us first consider the ellipse resulting from the intersection of a cylinder, having a circle for its base, with a plane. Let $x^2 + y^2 = r^2$ be the equation of the cylinder, and $ax + by + cz = d$ be the equation of the plane. The differential equations of this ellipse being $x dx + y dy = 0$, $adx + bdy + cdz = 0$, the angles α, β, γ , formed by the tangent with the axes x, y, z , will be determined by means of the equations

$$x \cos \alpha + y \cos \beta = 0, \quad A \cos \alpha + B \cos \beta + C \cos \gamma = 0, \quad \cos^2 \alpha + \cos^2 \beta + \cos^2 \gamma = 1.$$

Hence we shall find

$$\frac{\cos \alpha}{y} = \frac{\cos \beta}{-x} = \frac{\cos \gamma}{\frac{1}{c}(bx - ay)} = \pm \frac{1}{\left[r^2 + \left(\frac{bx - ay}{c}\right)^2\right]^{\frac{1}{2}}},$$

and we shall have for the equations of the tangent

$$x(x_1 - x) + y(y_1 - y) = 0, \quad a(x_1 - x) + b(y_1 - y) + c(z_1 - z) = 0, \quad \text{or } xx_1 + yy_1 = r^2, \\ ax_1 + by_1 + cz_1 = d.$$

In the same manner the equation of the normal plane will be found to be

$$c(x_1 y - y_1 x) + (bx - ay)(z_1 - z) = 0.$$

The equations of the tangent represent, as might have been expected, the first, the tangent to the circle which is the base of the cylinder, and the second, the plane of the curve itself.

We shall take for a second example the intersection of a conic surface, having a circle for its base, with a plane.

Let $x^2 + y^2 = a^2 z^2$ be the equation of the cone, and $ax + by + cz = d$ that of the plane. We shall find for the equations of the tangent

$$xx_1 + yy_1 = a^2 z z_1, \quad ax_1 + by_1 + cz_1 = d,$$

and for the equation of the normal plane

$$c(x_1 y - y_1 x) + (bx_1 - ay_1)a^2 z + (bx - ay)(z_1 - z - a^2 z) = 0.$$

The equations of the tangent represent, as might have been foreseen, the two planes, the first passing through the origin of the coordinates and one of the edges of the cone, and the other coinciding with the plane of the curve.

Let, for another example, $x^2 + y^2 + z^2 = r^2$, and $\left(x - \frac{r}{2}\right)^2 + z^2 = \frac{r^2}{4}$, be the equations of the curve. The first

belongs obviously to a sphere having its centre at the origin, and for radius r , and the second to a right cylinder having for its base a circle drawn in the plane of the x, z , passing through the origin of the coordinates, and the diameter of which is equal to the radius of the sphere. This curve will have for its projection on the plane of the x, y the parabola represented by the equation $y^2 = r(r - x)$, for its projection on the plane of the z, x , the circle which is the base of the cylinder, and for its projection on the plane of the z, y , the *lemniscata* represented by the equation $r^2 z^2 = y^2(r^2 - y^2)$. Therefore the tangent to the given curve will have for its projections on the coordinate planes the tangents to the parabola, the circle and the lemniscata, that is to say, the three lines represented by the equations

$$yy_1 + \frac{rx_1}{2} = r\left(r - \frac{x}{2}\right), \quad \left(x - \frac{r}{2}\right)x_1 + zz_1 = \frac{rx}{2}, \quad r^2 z z_1 - (r^2 - 2y^2)yy_1 = y^4.$$

As to the equation of the normal plane it may be put under the form

$$\frac{x_1}{x} - \frac{z_1}{z} = \frac{r}{2x} \left(\frac{y_1}{y} - \frac{z_1}{z}\right),$$

and then it is easy to verify that this plane contains the line drawn from the origin to the point of contact, since it passes through the origin of the coordinates.

We shall take for the last example the *helix*, or the curve of double curvature formed by a thread, wrapped round the surface of a cylinder, so as always to make the same angle with the axis. Let us suppose that the axis of the cylinder coincides with the axis of z , and that the basis of the cylinder is the circle represented by the equation $x^2 + y^2 = r^2$. If we consider this cylinder as being generated by the uniform revolution of a rectangular parallelogram round one of its sides, the *helix* may be conceived to be traced out by a point moving uniformly upon

Integral
Calculus.

Part III.

the other. Hence if we call p the angle which the radius, which we may imagine to describe the base of the cylinder by its rotation round the origin, makes in any position with the axis of x , and if we suppose that the point describing the helix is in the plane of the x, y , and on the axis of x when the radius begins its revolution, we shall have, in representing by x, y, z , the coordinates of the point of the helix corresponding to the angle p , $x = r \cos p$, $y = r \sin p$, and $z = arp$, a being a certain constant quantity depending on the ratio of the velocities of the radius and describing point. By eliminating p between these three equations we would find the two equations of the helix. But we may find the equations of the tangent and normal plane, without proceeding to that elimination, since the formulæ we have obtained are true whatever may be the independent variable. By differentiation, we find

$$dx = -r \sin p \, dp, \quad dy = r \cos p \, dp, \quad dz = ar \, dp.$$

Hence we shall get

$$\cos \alpha = \frac{\sin p}{\sqrt{1+a^2}}, \quad \cos \beta = \frac{\cos p}{\sqrt{1+a^2}}, \quad \cos \gamma = \frac{a}{\sqrt{1+a^2}}.$$

The last expression shows that the angle γ is a constant quantity, that is to say, that the angle which the tangent to the curve makes with the axis of z , or the axis of the cylinder, is constant. The equations of the tangent will be

$$\frac{x_1 - x}{-\sin p} = \frac{y_1 - y}{\cos p} = \frac{z_1 - z}{a},$$

and the equation of the normal plane $(y_1 - y) \cos p - (x_1 - x) \sin p + a(z_1 - z) = 0$.

(334.) The asymptotes of curves in space may be determined by means analogous to those which have been used to find the asymptotes of a plane curve. Let us first suppose that it is required to find the asymptotes not parallel to the plane of y, z , and let $y = ax + b$, $z = cx + d$ be the equations of one of them. Then if we derive from the equations of the curve the values of y and z in function of x , these values, for very great values of x , must become respectively equal to $ax + b$, and $cx + d$. Let $y = ax + b + l$ and $z = cx + d + m$ be the equations of the curve, l and m designating two functions of x which will vanish when x is infinite. Hence, for increasing values of x ,

$$\lim \frac{y}{x} = a, \quad \lim \frac{z}{x} = c, \quad \lim (y - ax) = b, \quad \lim (z - cx) = d.$$

Therefore to find the constant a and c it will suffice to make in the equations of the curve $y = px$, and $z = qx$, and then to find the limit, or limits, towards which converge p and q whilst the values of x increase indefinitely. These limits will be the values of a and c . After having found them, the values $ax + r$, $cx + s$ must be substituted for y and z in the equations of the curve and the limits, towards which converge the values of r and s , for increasing values of x be determined. These limits will be the values of b and d . To each system of finite values of the quantities a, b, c, d , will correspond an asymptote of the proposed curve. By a similar reasoning, but by exchanging between them the coordinates x, y, z , we might obtain the asymptotes which are not parallel to the plane of z, x , or to the plane of z, y .

The asymptotes of curves in space might also be determined by observing that their projections upon each of the three coordinate planes are, in general, the asymptotes of the projection of the curve. It must only be observed that the projection of one of the first asymptotes would be reduced to a point, if that asymptote were perpendicular to the plane. Then this point would be a *stop point* of the projection of the curve.

If we take for an example the hyperbola which is the intersection of a plane and of an hyperboloid represented by the two equations

$$fx + gy + hz = 0, \text{ and } Ax^2 + By^2 + Cz^2 + 2Dyz + 2Ezx + 2Fxy = L,$$

we shall have by substituting $y = px$ and $z = qx$

$$(f + gp + hq)x = 0, \quad A + Bp^2 + Cq^2 + 2Dpq + 2Eq + 2Fp = \frac{L}{x^2}.$$

The limits towards which converge p and q whilst the values of x increase indefinitely, or the values of p and q corresponding to $x = \infty$ will be determined by the two equations

$$f + gp + hq = 0, \quad A + Bp^2 + Cq^2 + 2Dpq + 2Eq + 2Fp = 0.$$

The values of p and q being found, and designated by a and c , we shall substitute $ax + r$ and $cx + s$ for y and z in the two equations of the curve. Then we shall have to determine the values of r and s corresponding to $x = \infty$, recollecting that a and b are the values of p and q which satisfy the two equations above,

$$gr + hs = 0, \quad 2Bar + 2Ccs + 2D(ar + cs) + 2Es + 2Fr = 0.$$

These two equations give immediately $r = 0$ and $s = 0$. Hence, if the curve have asymptotes their equations will be simply of the form $y = px$ and $z = qx$, that is to say that they will pass through the origin of the coordinates. If, moreover, we consider the form of the equations by means of which the values of p and q are to be determined it will become evident that the curve has for its asymptote the straight lines represented by the equations

$$fx + gy + hz = 0, \quad Ax^2 + By^2 + Cz^2 + 2Dyz + 2Ezx + 2Fxy = 0.$$

(335.) We shall not enter here into any discussions about the singular or remarkable points of a curve in space, because, in general, these points have for their projections, on the three coordinate planes, points which present the same circumstances with respect to the projections of the curve.

(336.) Let $u = 0$ be the equation of a curve surface, u designating a function of three rectangular coordinates x, y, z . If through a given point on this surface, the coordinates of which are represented by x, y, z , we imagine another surface to pass, we shall have a certain curve resulting from the intersection of the two surfaces. The tangent drawn to that curve through the given point will be the line of intersection of two planes represented by the equations (a) given in number (331.) Now it is easy to see that one of these planes, namely, that of which the variable coordinates satisfy the equation

$$(x_1 - x) \frac{du}{dx} + (y_1 - y) \frac{du}{dy} + (z_1 - z) \frac{du}{dz} = 0,$$

will be independent of the nature of the second surface, and also consequently of the nature of the curve of intersection. Hence all the curves drawn on the first surface and passing through the given point (x, y, z) will have their tangents in that point contained in one plane. This plane, represented by the above equation, is the *tangent plane* to the given surface, at the given point.

The reasonings which have just been used would still subsist, and consequently the equation of the tangent plane would preserve the same form, if, in the function u , the variables x, y, z were referred to three oblique instead of three rectangular axes.

If the equation of the surface $u = 0$ be differentiated in considering u as a function of three independent variables, x, y, z , we shall find

$$\frac{du}{dx} dx + \frac{du}{dy} dy + \frac{du}{dz} dz = 0,$$

and if we compare this equation with the equation of the tangent plane,

$$(x_1 - x) \frac{du}{dx} + (y_1 - y) \frac{du}{dy} + (z_1 - z) \frac{du}{dz} = 0,$$

we see that to obtain this equation, it suffices to replace, in the differential equation of the surface, the differentials dx, dy, dz , by the differences $x_1 - x, y_1 - y, z_1 - z$.

(337.) If through the point (x, y, z) on the surface, we draw a straight line in a direction perpendicular to the tangent plane, this line will be the *normal* at the given point. Let λ, μ , and ν be the angles formed by this normal with the three axes. The tangent plane being perpendicular to the normal, its equation may be put under the form

$$(x_1 - x) \cos \lambda + (y_1 - y) \cos \mu + (z_1 - z) \cos \nu = 0.$$

But we have found for the equation of the same plane,

$$(x_1 - x) \frac{du}{dx} + (y_1 - y) \frac{du}{dy} + (z_1 - z) \frac{du}{dz} = 0,$$

therefore, in order that these two equations should agree, we must have

$$\frac{\cos \lambda}{\cos \nu} = \frac{\left(\frac{du}{dx}\right)}{\left(\frac{du}{dz}\right)}, \quad \frac{\cos \mu}{\cos \nu} = \frac{\left(\frac{du}{dy}\right)}{\left(\frac{du}{dz}\right)}.$$

These equations, combined with the relation $\cos^2 \lambda + \cos^2 \mu + \cos^2 \nu = 1$, give

$$\frac{\cos \lambda}{\left(\frac{du}{dx}\right)} = \frac{\cos \mu}{\left(\frac{du}{dy}\right)} = \frac{\cos \nu}{\left(\frac{du}{dz}\right)} = \pm \frac{1}{\sqrt{\left(\frac{du}{dx}\right)^2 + \left(\frac{du}{dy}\right)^2 + \left(\frac{du}{dz}\right)^2}}.$$

If to shorten the equation we make the denominator of this last expression equal to r , we shall have

$$\cos \lambda = \frac{1}{r} \frac{du}{dx}, \quad \cos \mu = \frac{1}{r} \frac{du}{dy}, \quad \cos \nu = \frac{1}{r} \frac{du}{dz}.$$

This understood, it becomes very easy to find the two equations of the normal drawn through the point (x, y, z) . If we designate by x_1, y_1, z_1 , the variable coordinates of any point of this straight line, we shall have

$$\frac{x_1 - x}{\cos \lambda} = \frac{y_1 - y}{\cos \mu} = \frac{z_1 - z}{\cos \nu};$$

and then, if we replace the quantities $\cos \lambda, \cos \mu, \cos \nu$, by their values in function of the partial differential coefficients $\frac{du}{dx}, \frac{du}{dy}, \frac{du}{dz}$, we find

$$\frac{(x_1 - x)}{\left(\frac{du}{dx}\right)} = \frac{(y_1 - y)}{\left(\frac{du}{dy}\right)} = \frac{(z_1 - z)}{\left(\frac{du}{dz}\right)},$$

which are the two required equations of the normal.

Integral
Calculus.

(338.) The acute angle formed by the tangent plane at the point x, y, z , with the plane of x, y , is called the *inclination of the tangent plane*, or the inclination of the surface at that point. This same angle is obviously equal to the acute angle formed by the normal with the axis of z , therefore if we designate it by τ we shall have

$$\cos \tau = \pm \frac{1}{r} \frac{du}{dz}, \text{ or } \sec \tau = \pm \frac{r}{\left(\frac{du}{dz}\right)}.$$

(339.) If the given surface were represented by the equation $u = c$ instead of $u = 0$, c being a constant, the equation of the tangent plane and normal would still be

$$(x_1 - x) \frac{du}{dx} + (y_1 - y) \frac{du}{dy} + (z_1 - z) \frac{du}{dz} = 0 \quad \frac{x_1 - x}{\left(\frac{du}{dx}\right)} = \frac{y_1 - y}{\left(\frac{du}{dy}\right)} = \frac{z_1 - z}{\left(\frac{du}{dz}\right)}.$$

If, in the first of these equations, we consider the coordinates x_1, y_1, z_1 as constant quantities, and the coordinates x, y, z as variable, it will no longer represent the equation of the tangent plane to the surfaces $u = 0$, or $u = c$, but it will be the equation of another surface which is the locus of all the points where the surfaces derived from the equation $u = c$, by substituting successively different values for the constant c , are touched by the plane passing through the point (x_1, y_1, z_1) .

In the same manner, if in the other equations, those of the normal, the coordinates x, y, z are supposed to be variable, and x_1, y_1, z_1 to be constant, they will belong to a curve which will be the locus of all the points where the surfaces just mentioned are met by the normal drawn to them through the point x_1, y_1, z_1 .

(340.) When the equation of the surface is resolved with respect to one of the variables, that is to say, is of the form $z = f(x, y)$ or $f(x, y) - z = 0$, we have $u = f(x, y) - z$.

Let $\frac{df(x, y)}{dx} = p, \frac{df(x, y)}{dy} = q$, we shall have clearly $\frac{du}{dx} = p, \frac{du}{dy} = q, \frac{du}{dz} = -1$, and the differential equation of the surface will become $p dx + q dy - dz = 0$, or $dz = p dx + q dy$. The equations of the tangent plane and of the normal become also respectively

$$z_1 - z = p(x_1 - x) + q(y_1 - y) \text{ and } x_1 - x + p(z_1 - z) = 0, y_1 - y + q(z_1 - z) = 0.$$

In this case, we shall have, also, $\cos \tau = \frac{1}{\sqrt{p^2 + q^2 + 1}}$, or $\sec \tau = \sqrt{1 + p^2 + q^2}$.

(341.) Let us suppose now that the curve surface is represented by an equation of the form

$$u + v + w + \dots = c, \quad u, v, w, \dots$$

designating several functions of the variables x, y, z . The equation of the tangent plane may then be put under the following form

$$\left(\frac{du}{dx} + \frac{dv}{dx} + \frac{dw}{dx} + \dots\right)x_1 + \left(\frac{du}{dy} + \frac{dv}{dy} + \frac{dw}{dy} + \dots\right)y_1 + \left(\frac{du}{dz} + \frac{dv}{dz} + \frac{dw}{dz} + \dots\right)z_1 =$$

$$x \frac{du}{dx} + y \frac{du}{dy} + z \frac{du}{dz} + x \frac{dv}{dx} + y \frac{dv}{dy} + z \frac{dv}{dz} + x \frac{dw}{dx} + y \frac{dw}{dy} + z \frac{dw}{dz} + \dots$$

Let us assume that u, v, w , &c. are integral and homogeneous functions, the first of the m^{th} degree, the second of the degree $m - 1$, the third of the degree $m - 2$, &c., the surface will then be a surface of the m^{th} degree. In this case we shall have by the theorem relative to homogeneous functions,

$$x \frac{du}{dx} + y \frac{du}{dy} + z \frac{du}{dz} + x \frac{dv}{dx} + y \frac{dv}{dy} + z \frac{dv}{dz} + \dots = mu + (m - 1)v + (m - 2)w + \dots,$$

and consequently the equation of the tangent plane becomes

$$\left(\frac{du}{dx} + \frac{dv}{dx} + \frac{dw}{dx} + \dots\right)x_1 + \left(\frac{du}{dy} + \frac{dv}{dy} + \frac{dw}{dy} + \dots\right)y_1 + \left(\frac{du}{dz} + \frac{dv}{dz} + \frac{dw}{dz} + \dots\right)z_1 =$$

$$z_1 = mu + (m - 1)v + (m - 2)w + \dots = mc - v - 2w - \&c.$$

If in this last formula we consider the coordinates x_1, y_1, z_1 as constant quantities, and the coordinates x, y, z as variables, it will represent the equation of a surface of the $(m - 1)$ degree, which will contain the points of contact of the first with the tangent planes drawn through the point x_1, y_1, z_1 . Hence if the first surface is of the second degree the second will be of the first. This result may be stated in the following manner.

If through a given point, tangent planes are drawn to a surface of the second degree, all the points of contact will be situated in one plane.

If we suppose $v = 0, w = 0$, that is, if we suppose the equation of the surface reduced to $u = c$, u designating an integral and homogeneous function of the degree m , the above equation of the tangent plane becomes simply

$$\frac{du}{dx}x' + \frac{du}{dy}y' + \frac{du}{dz}z' = mc.$$

(342.) The tangent plane drawn to a surface through a given point (x, y, z) may have only that point common with the surface, or it may touch it in all the points of one or several lines, or it may also intersect it. In these

Integral Calculus. two last cases, if we designate by $f(x, y, z) = 0$ the equation of the proposed surface, and by x_1, y_1, z_1 , the coordinates of any point of the line or lines common to the surface and to the tangent plane, these coordinates must clearly verify the two equations

Part III.

$$f(x_1, y_1, z_1) = 0, \quad \frac{d \cdot f(x, y, z)}{d x} (x_1 - x) + \frac{d \cdot f(x, y, z)}{d y} (y_1 - y) + \frac{d \cdot f(x, y, z)}{d z} (z_1 - z) = 0.$$

When it is possible to draw, on the surface, through a point (x, y, z) one or several straight lines, each of these lines coincides necessarily with its tangent, and, consequently, is contained in the tangent plane at that point. Then, the elimination of z_1 between the two above equations produces an equation between x_1 and y_1 , which is satisfied by taking for y_1 a linear function of x_1 . If this take place not only for a particular point of the surface under consideration, but for every point of it, this surface will be of the number of those which can be generated by a straight line, and which are denominated by the French analysts *surfaces réglées*. Among these must be noticed those which are touched by each tangent plane at every point of the generating line common to the plane and to the surface; they admit of developement upon a plane, and are called by the French *surfaces développables*; then those which do not admit of developement upon a plane, are called by the French *surfaces gauches*. Cylindrical and conical surfaces belong to the first division. A cylindrical surface, in general, may be considered as generated by a straight line which in every position is parallel to the same straight line. A conical surface, in general, may be considered as generated by a straight line which, in every position, passes through the same point.

We shall now give a few examples of the preceding formulæ.

1. Let the proposed surface be a cylindrical surface, the generating line of which is parallel to the axis of z . This surface will have for its basis a certain curve drawn in the plane of the x, y , and if $f(x, y) = 0$ be the equation of this curve, it will also be the equation of the cylindrical surface. Let us suppose, for brevity sake,

$$\frac{d \cdot f(x, y)}{d x} = \phi(x, y) \text{ and } \frac{d f(x, y)}{d y} = \psi(x, y), \text{ then the equation of the tangent plane will become } (x_1 - x) \phi$$

$(x, y) + (y_1 - y) \psi(x, y) = 0$, and those of the normal $(x_1 - x) \psi(x, y) - (y_1 - y) \phi(x, y) = 0$ and $z_1 = z$. These equations show that the tangent plane is parallel to the axis of z , and the normal perpendicular to the same axis, and moreover that the tangent plane will touch the surface all along the generating line passing through the point of contact.

2. Let us consider, in the next place, a conical surface, the summit or centre of which, that is the point where all the generating lines meet, coincides with the origin of coordinates. Let us conceive besides that the basis of this surface is a curve, situated in a plane parallel to the plane of x, y , which meets the axis of z at a distance of the origin $= 1$. Let x' and y' be the coordinates of any point of that curve, and $f(x', y') = 0$ its equation. The

generating line passing through the point (x', y') will be represented by the two equations $\frac{x}{z} = x', \frac{y}{z} = y'$. If

then we eliminate between these two equations, and the equation $f(x', y') = 0$, the two quantities x' and y' , it is

clear that the equation $f\left(\frac{x}{z}, \frac{y}{z}\right) = 0$, which we shall obtain, will be true for any point of any of the generating

lines, and therefore that it will be the equation of the conical surface. This understood, if we assume, as in the

preceding example, $\frac{d \cdot f(x, y)}{d x} = \phi(x, y)$, and $\frac{d f(x, y)}{d y} = \psi(x, y)$, we shall have for the differential equation of the conical surface

$$\phi\left(\frac{x}{z}, \frac{y}{z}\right) dx + \psi\left(\frac{x}{z}, \frac{y}{z}\right) dy - \frac{1}{z} \left\{ x \phi\left(\frac{x}{z}, \frac{y}{z}\right) + y \psi\left(\frac{x}{z}, \frac{y}{z}\right) \right\} dz = 0.$$

If now we designate by x_1, y_1, z_1 , the coordinates of any point of the tangent plane or of the normal at the point (x, y, z) , we shall find for the equation of the tangent plane

$$(x_1 - x) \phi\left(\frac{x}{z}, \frac{y}{z}\right) + (y_1 - y) \psi\left(\frac{x}{z}, \frac{y}{z}\right) - \frac{1}{z} \left\{ x \phi\left(\frac{x}{z}, \frac{y}{z}\right) + y \psi\left(\frac{x}{z}, \frac{y}{z}\right) \right\} (z_1 - z) = 0, \text{ or after reduction}$$

$$x_1 \phi\left(\frac{x}{z}, \frac{y}{z}\right) + y_1 \psi\left(\frac{x}{z}, \frac{y}{z}\right) = \left\{ \frac{x}{z} \phi\left(\frac{x}{z}, \frac{y}{z}\right) + \frac{y}{z} \psi\left(\frac{x}{z}, \frac{y}{z}\right) \right\} z_1 = 0.$$

The equation of the normal will be

$$\frac{x_1 - x}{\phi\left(\frac{x}{z}, \frac{y}{z}\right)} = \frac{y_1 - y}{\psi\left(\frac{x}{z}, \frac{y}{z}\right)} = \frac{z(z - z_1)}{x \phi\left(\frac{x}{z}, \frac{y}{z}\right) + y \psi\left(\frac{x}{z}, \frac{y}{z}\right)}.$$

It may be remarked that since the equation of the tangent plane remains the same when x, y , and z are made to

vary in such a manner as not to change the values of the ratios $\frac{x}{z}, \frac{y}{z}$, it follows that each tangent plane will touch

the surface at every point of the generating line passing through the given point of contact. Here the two equations which are to be verified by linear functions of z_1 , substituted for y_1 and z_1 , are

$$f\left(\frac{x_1}{z_1}, \frac{y_1}{z_1}\right) = 0 \left(\frac{x_1}{z_1} - \frac{x}{z}\right) \phi\left(\frac{x}{z}, \frac{y}{z}\right) + \left(\frac{y_1}{z_1} - \frac{y}{z}\right) \psi\left(\frac{x}{z}, \frac{y}{z}\right) = 0.$$

It is obvious that by taking $\frac{x_1}{z_1} = \frac{x}{z}$ and $\frac{y_1}{z_1} = \frac{y}{z}$, these equations are satisfied, since we must always have $f\left(\frac{x}{z}, \frac{y}{z}\right) = 0$, and that $\frac{x_1}{z_1} = \frac{x}{z}$, and $\frac{y_1}{z_1} = \frac{y}{z}$ represent a straight line passing through the origin or the centre of the conical surface. Hence this straight line is common to the tangent plane and to the surface.

3. Let the equation of the surface be $\frac{x^2}{a^2} + \frac{y^2}{b^2} = 2\frac{z}{c}$, that is to say, let the surface be an *elliptical paraboloid*. We shall find for the equation of the tangent plane

$$\frac{x}{a^2}(x_1 - x) + \frac{y}{b^2}(y_1 - y) = \frac{1}{c}(z_1 - z), \text{ or } \frac{xx_1}{a^2} + \frac{yy_1}{b^2} = \frac{z_1 + z}{c}.$$

The equations of the normal will be

$$\frac{a^2(x_1 - x)}{x} = \frac{b^2(y_1 - y)}{y} = -c(z_1 - z) = \frac{x(x_1 - x) + y(y_1 - y) + 2z(z_1 - z)}{0}, \text{ or}$$

$$\frac{a^2(x_1 - x)}{x} = \frac{b^2(y_1 - y)}{y}, \quad x(x_1 - x) + y(y_1 - y) + 2z(z_1 - z) = 0.$$

To ascertain whether the tangent plane has more than one point common with the surface, it suffices to examine if several systems of real values of x_1, y_1, z_1 may be found to verify the two equations

$$\frac{x_1^2}{a^2} + \frac{y_1^2}{b^2} = \frac{2z_1}{c}, \quad \frac{xx_1}{a^2} + \frac{yy_1}{b^2} = \frac{z + z_1}{c}.$$

From these two equations, and from the equation $\frac{x^2}{a^2} + \frac{y^2}{b^2} = \frac{2z}{c}$ we easily derive $\frac{x_1^2}{a^2} + \frac{y_1^2}{b^2} + \frac{x^2}{a^2} + \frac{y^2}{b^2} - \frac{2xx_1}{a^2} -$

$\frac{2yy_1}{b^2} = 0$, or $\left(\frac{x_1 - x}{a}\right)^2 + \left(\frac{y_1 - y}{b}\right)^2 = 0$, an equation which can only be satisfied by making $x_1 = x$ and $y_1 = y$,

and these values give $z_1 = z$. Therefore the point (x, y, z) is the only point that is at the same time on the tangent plane and on the surface.

4. Let us next consider the *hyperbolic paraboloid* represented by the equation $\frac{x^2}{a^2} - \frac{y^2}{b^2} = \frac{2z}{c}$. All sections of this surface parallel to the plane of x, y are hyperbolas, and all sections by planes perpendicular to the axis of x or to the axis of y are parabolas. The section by the plane of the x, y is represented by the equation $\frac{x^2}{a^2} - \frac{y^2}{b^2} = 0$, and consequently is composed of two straight lines passing through the origin of the coordinates, and represented by the two equations $\frac{x}{a} - \frac{y}{b} = 0$, $\frac{x}{a} + \frac{y}{b} = 0$.

The equation of the tangent plane is

$$\frac{x(x_1 - x)}{a^2} - \frac{y(y_1 - y)}{b^2} = \frac{z_1 - z}{c}, \text{ or } \frac{xx_1}{a^2} - \frac{yy_1}{b^2} = \frac{z_1 + z}{c},$$

and the equations of the normal are

$$\frac{a^2(x_1 - x)}{x} - \frac{b^2(y_1 - y)}{y} = 0, \quad x(x_1 - x) - y(y_1 - y) + 2z(z_1 - z) = 0.$$

To obtain the lines which, passing through the point (x, y, z) , are common to the surface and to the tangent plane, we must find the values of or relations between x_1, y_1 , and z_1 , which satisfy the two equations

$$\frac{x_1^2}{a^2} - \frac{y_1^2}{b^2} = \frac{2z_1}{c}, \quad \frac{xx_1}{a^2} - \frac{yy_1}{b^2} = \frac{z + z_1}{c}.$$

These being combined with $\frac{x^2}{a^2} - \frac{y^2}{b^2} = \frac{2z}{c}$, give

$$\frac{x_1^2}{a^2} - \frac{y_1^2}{b^2} + \frac{x^2}{a^2} - \frac{y^2}{b^2} - 2\left(\frac{xx_1}{a^2} - \frac{yy_1}{b^2}\right) = 0, \text{ or } \left(\frac{x_1 - x}{a}\right)^2 - \left(\frac{y_1 - y}{b}\right)^2 = 0$$

and therefore

$$\frac{x_1 - x}{a} = \frac{y_1 - y}{b}, \text{ or } \frac{x_1 - x}{a} = -\frac{y_1 - y}{b}.$$

Integral
Calculus.

Part III.

Each of these two last equations, together with the equation $\frac{x x_1}{a^2} - \frac{y y_1}{b^2} = \frac{z + z_1}{c}$, represent a straight line. There-

fore there are two straight lines passing through the point x, y, z , which are at the same time on the hyperbolic paraboloid, and in the tangent plane. But, in this case, the tangent plane touches the surface only at the point (x, y, z) and not in every point where it meets the surface. Hence the hyperbolic paraboloid does not admit of developement upon a plane, and belongs to the class of *surfaces gauches*. We shall not demonstrate this proposition here, because in the sequel we shall give a general rule to ascertain whether or not a tangent plane touches a surface in every point of the line or lines where it meets it.

In the same manner we would find respectively for the equations of the tangent planes and normals.

1. To the ellipsoid represented by the equation $\frac{x^2}{a^2} + \frac{y^2}{b^2} + \frac{z^2}{c^2} = 1$,

$$\frac{x x_1}{a^2} + \frac{y y_1}{b^2} + \frac{z z_1}{c^2} = 1, \quad \frac{a^2 (x_1 - x)}{x} = \frac{b^2 (y_1 - y)}{y} = \frac{c^2 (z_1 - z)}{z}.$$

2. To the hyperboloid of two surfaces, or the hyperboloid of two summits (the *hyperboloïde à deux nappes* of the French) represented by the equation $\frac{x^2}{a^2} + \frac{y^2}{b^2} - \frac{z^2}{c^2} = -1$,

$$\frac{x x_1}{a^2} + \frac{y y_1}{b^2} - \frac{z z_1}{c^2} = -1, \quad \frac{a^2 (x_1 - x)}{x} - \frac{b^2 (y_1 - y)}{y} = \frac{c^2 (z_1 - z)}{-z}.$$

3. To the hyperboloid of one surface, or the hyperboloid of four summits (the *hyperboloïde à une nappe* of the French) represented by the equation $\frac{x^2}{a^2} + \frac{y^2}{b^2} - \frac{z^2}{c^2} = 1$,

$$\frac{x x_1}{a^2} + \frac{y y_1}{b^2} - \frac{z z_1}{c^2} = 1, \quad \frac{a^2 (x_1 - x)}{x} = \frac{b^2 (y_1 - y)}{y} = \frac{c^2 (z_1 - z)}{-z}.$$

We shall find that for this last hyperboloid that there are also two straight lines, passing through the point of contact, which are, at the same time, on the surface and on the tangent plane, but that this plane touches the surface only in one point, and consequently that the surface is a *surface gauche*.

For the last example we shall take the curve surface which is generated by a horizontal line passing constantly through the vertical axis of z , and whose extremity is always found in the helix of the last example, given (335.).

If a plane pass through the axis of z , it will meet the generating line in one and even in an infinite number of its positions; and if any point whatever be taken in this line, whose coordinates are z, x, y , then z will bear the same ratio to the angle described by the plane from its first position, as in the case of the helix, which guides the generating line, and we shall have for the equation of the surface,

$$z = a r \tan^{-1} \frac{y}{x}, \quad \text{or } y = x \tan \frac{z}{a r},$$

and for the differential equation

$$dz = a r \frac{x dy - y dx}{x^2 + y^2}, \quad \text{or } \frac{x^2 + y^2}{a r} dz = x dy - y dx.$$

Hence the equations of the tangent plane and normal will be

$$x y_1 - y x_1 = \frac{x^2 + y^2}{a r} (z_1 - z), \quad \frac{a r (z_1 - z)}{x^2 + y^2} = \frac{y_1 - y}{-x} = \frac{x_1 - x}{y}.$$

By means of these equations we may easily ascertain various properties of the surface. It may be proved, for instance, that there are an infinite number of straight lines common to the surface and to the tangent plane, one of which is the generating line passing through the point of contact, or the perpendicular drawn through the point of contact to the axis of z . It may also be remarked, that the axis of z is entirely contained in the surface under consideration, since the equation of the surface is satisfied for $x = 0$, and $y = 0$, independently of any particular value of z . To have the equation of the tangent plane drawn through one of the points of the axis of z , we must write, in the general equation, $x = 0$ and $y = 0$, or rather $x = 0$ in the

equation $y_1 - x_1 \tan \frac{z}{a r} = \frac{x}{a r} (z_1 - z) \sec^2 \frac{z}{a r}$, resulting from the elimination of y between the equation of the surface and the equation of the tangent plane. Thus we find for the equation of the tangent plane in one

point of the axis of z , $\frac{y_1}{x_1} = \tan \frac{z}{a r}$. Therefore this plane will contain the axis of z , and all the generating lines

which make the same angle with the axis of x . It may also be remarked, that if x or y be very large, the normal is perpendicular to the plane of x, y , and the tangent plane parallel to it.

This is the surface presented by the superior and inferior surface of a staircase, attached to a vertical column round which it winds, or to the concave wall of a circular tower, its thickness being supposed to be uniform, and no regard being paid to irregularities caused by the form of the steps.

(343.) There are sometimes points upon curve surfaces through which an infinite number of tangent planes.

Integral
Calculus.

Part III.

may be drawn. For each point of this kind the values of $\cos \lambda$, $\cos \mu$, $\cos \nu$, must become undeterminate, and this can only take place in two cases, 1. when one at least of the quantities $\frac{du}{dx}$, $\frac{du}{dy}$, $\frac{du}{dz}$, becomes undeterminate ;

2. when these three quantities become at once equal to nothing or infinity. In both these cases the substitution of the values of x , y , z , transform the equation of the tangent plane to an identical equation, or at least to an equation which contains an arbitrary constant.

Let us consider, for instance, the centre of the conical surface represented by the equation $x^2 + y^2 = r^2 z^2$. Since this centre is placed at the origin of coordinates, the corresponding values of x , y , and z will be equal to nothing, and being substituted in the equation of the tangent plane $x_1 x + y_1 y = r^2 z_1 z$, will make both sides vanish. But if we introduce polar coordinates ρ and p instead of x and y , by making $x = \rho \cos p$, and $y = \rho \sin p$, the equation of the surface becomes $z = \pm \frac{\rho}{r}$, and the equation of the tangent plane $x_1 \cos p + y_1 \sin p = r z_1$. This last

equation contains only one of the polar coordinates, namely p , and this angle, which is determined for every point of the surface other than the centre, is undeterminate for the centre itself, and then changes itself into an arbitrary constant. To the various values which this arbitrary constant may receive correspond an infinite number of planes represented by the equation $x_1 \cos p + y_1 \sin p = r z_1$.

Centres and Diameters of Curve Surfaces, and Curves in Space, and Axes of Curve Surfaces.

(344.) Generally the centre of a curve, or a curve surface, is a point such that the radii drawn from it to the curve, or curve surface, are equal to two and two and in opposite direction. When a curve, or a curve surface, has a centre, and that this point has been taken for the origin of coordinates, no alteration is produced in the equations, or equation, of this curve, or curve surface by changing x into $-x$, y into $-y$, z into $-z$, &c. When the centre coincides with the point which has for its coordinates a , b , c , these equations are not altered neither by substituting $2a - x$ for x , $2b - y$ for y , $2c - z$ for z . These propositions are obvious consequences of the definition of a centre.

It is necessary to remark, that a curve, or a curve surface, may have an infinite number of centres. Thus, for instance, if we have a curve situated in a plane perpendicular to a straight line, the centre of which is situated on that straight line, if then we imagine a cylindrical surface having that curve for its base, and the generating line of which should be parallel to the straight line just mentioned, it is obvious that every point of that line will be a centre of the cylindrical surface.

Any straight line drawn through the centre of a curve, or a curve surface, is a diameter of this curve, or curve surface.

An *axis* of a curve surface is a straight line drawn in such a manner as to divide in two symmetrical parts each of the plane curves, which are obtained by cutting the surface by planes which contain this same straight line. Such an axis is necessarily a normal to the curve surface at the points where it meets it, unless the tangent plane drawn through that point of meeting should become undeterminate. Moreover, each point of the axis is obviously a centre of the curve obtained by cutting the surface by a plane drawn perpendicularly to the axis through that point. Hence if this axis coincide with the axis of x , and if the coordinate lines be rectangular, the equation of the surface will not be altered by substituting $-y$ for y , and $-z$ for z .

(345.) Let now $u = f(x, y, z) = 0$ be the equation of a surface limited on all sides, and let the point which we suppose to be the only centre of the surface be designated by 0. If this surface admit one or several axes the point 0 will be situated upon each of them, for the intersection of the surface with planes drawn through this point, in directions perpendiculars to the axis, will be curves having for only centre the point 0. If for greater simplicity we place the origin of coordinates at the point 0, a line drawn through the origin to the point of the surface, the coordinates of which are x , y , z , will make angles with the three coordinate axes the cosines of which are proportional to x , y , z ; and the normal drawn through the same point will make angles with the same lines the cosines of which are proportional to $\frac{du}{dx}$, $\frac{du}{dy}$, $\frac{du}{dz}$. This understood, let us imagine that the line drawn from the point 0 to the

point x , y , z , coincides with one of the axes of the curve surface. In that case, the normal at the point (x, y, z) coincides with the axis of the curve surface, therefore the quantities $\frac{du}{dx}$, $\frac{du}{dy}$, $\frac{du}{dz}$, are proportional to the quantities

x , y , z , and we shall have, consequently, $\frac{(\frac{du}{dx})}{x} = \frac{(\frac{du}{dy})}{y} = \frac{(\frac{du}{dz})}{z}$. This result would still be true if the proposed surface were represented by the equation $u = c$ instead of the equation $u = 0$, c designating a constant quantity.

The three equations $u = c$, $\frac{(\frac{du}{dx})}{x} = \frac{(\frac{du}{dy})}{y} = \frac{(\frac{du}{dz})}{z}$, will be sufficient to determine the coordinates x , y , z , of the points where the normals drawn through the origin to the surface $u = c$ meet this same surface. To each of these normals answer a particular system of values of the variables x , y , z , and these values being substituted in the formula

$$\frac{\cos \lambda}{x} = \frac{\cos \mu}{y} = \frac{\cos \nu}{z} = \pm \frac{1}{\sqrt{x^2 + y^2 + z^2}},$$

give the angles λ , μ , and ν , which the normal makes with the coordinate axis. If then it be required to determine whether the normal under consideration is an axis of the surface $u = c$, it will be sufficient to cut this surface by planes drawn in a direction perpendicular to the axis, and to examine whether each curve of intersection has a centre situated on the normal itself. But if we take on the normal a point situated at a distance κ from the origin, the coordinates of this point will be $\kappa \cos \lambda$, $\kappa \cos \mu$, $\kappa \cos \nu$, and the plane drawn perpendicularly to the normal through the same point will be represented by the equation $x \cos \lambda + y \cos \mu + z \cos \nu = \kappa$; therefore we shall have only to examine whether the system of the two equations $x \cos \lambda + y \cos \mu + z \cos \nu = \kappa$, and $f(x, y, z) = c$ is altered by the substitution of $2\kappa \cos \lambda - x$, $2\kappa \cos \mu - y$, $2\kappa \cos \nu - z$, for x, y, z ; and since the first of these two equations will not be changed by that substitution, it will be sufficient to verify whether the equation $f(2\kappa \cos \lambda - x, 2\kappa \cos \mu - y, 2\kappa \cos \nu - z) = c$ may result, whatever be the value of κ , of the combination of the two equations $x \cos \lambda + y \cos \mu + z \cos \nu = \kappa$, and $u = c$.

In the case where u is an homogeneous function of the m^{th} degree, we have

$$x \frac{du}{dx} + y \frac{du}{dy} + z \frac{du}{dz} = mu,$$

and since $\frac{(du)}{dx} = \frac{(du)}{dy} = \frac{(du)}{dz}$, each of these quantities will also be equal to $\frac{mu}{x^2 + y^2 + z^2}$. Consequently, if

we designate by r the radius vector drawn through the origin to the point (x, y, z) , that is, if we make

$x^2 + y^2 + z^2 = r^2$, we shall get $\frac{(du)}{dx} = \frac{(du)}{dy} = \frac{(du)}{dz} = \frac{mc}{r^2}$. It is essential to observe that the equations

$\frac{(du)}{dx} = \frac{(du)}{dy} = \frac{(du)}{dz}$ are those which determine for the surface $u = 0$, or $u = c$, the values maxima and

minima of the function $x^2 + y^2 + z^2$, that is, the values maxima and minima of the radius vector. Therefore when a curve surface has one or several axes, which pass through the origin of the coordinates, the radius vector must coincide with one of these axes to become a maximum or a minimum.

On the Differential of the Arc of a Curve in Space.

(346.) Let x, y, z be the coordinates of a point of a curve in space represented by two equations between these quantities, and let s designate the length of an arc of this curve reckoned from that point. Two of the coordinates x, y, z are functions of the third, and it is obvious that the arc s is also a function of the same independent variable. Let it be proposed now to find the differential of that unknown function. For that purpose let $x + h, y + \kappa, z + l$, be the coordinates of another point of the curve situated at a very small distance from the point (x, y, z) . The length of the chord joining these two points is clearly $\sqrt{h^2 + \kappa^2 + l^2}$. Let also m represent the length of

the corresponding arc. Then the ratio $\frac{m}{\sqrt{h^2 + \kappa^2 + l^2}}$, that is, the ratio of the arc to the chord, will be greater

than one, but the nearer the second point will be to the first, the nearer will the ratio be equal to one, or, in other words, one is the limit of that ratio. Moreover, at the limit, we have $m = ds$, $h = dx$, $\kappa = dy$, and $l = dz$, therefore

$$1 = \frac{ds}{\sqrt{dx^2 + dy^2 + dz^2}}, \quad \text{or } ds = \sqrt{dx^2 + dy^2 + dz^2}.$$

If x be taken for the independent variable, and if we make $\frac{dy}{dx} = p$, and $\frac{dz}{dx} = q$, we shall have $ds = dx \sqrt{1 + p^2 + q^2}$.

This value of $\sqrt{dx^2 + dy^2 + dz^2}$ being substituted in the expressions which have been found (330.) for the cosines of the angles which a tangent to a curve in space makes with the axes of the three coordinates, they will become

$$\cos \alpha = \frac{dx}{ds}, \quad \cos \beta = \frac{dy}{ds}, \quad \cos \gamma = \frac{dz}{ds}.$$

The acute angle formed by the tangent at the point (x, y, z) with the axis of x , is called the *inclination of the tangent*, or the *inclination of the curve* with respect to that axis, it is obviously equal to, or supplement of, the angle α .

(347.) Let us consider now any two curves. Let x, y, z be the coordinates of any point of the first, and s its distance to a certain point on the same curve. Let x_1, y_1, z_1 and s_1 represent the analogous quantities with respect to the second curve. We shall have

$$ds^2 = dx^2 + dy^2 + dz^2, \text{ and } ds_1^2 = dx_1^2 + dy_1^2 + dz_1^2.$$

The tangent to the first curve, at the point (x, y, z) , will make with the axis certain angles the cosines of which are $\frac{dx}{ds}, \frac{dy}{ds}, \frac{dz}{ds}$, and the tangent to the second curve, at the point (x_1, y_1, z_1) , will make, with the same axis, angles the cosines of which are $\frac{dx_1}{ds_1}, \frac{dy_1}{ds_1}, \frac{dz_1}{ds_1}$. Therefore if we call δ the angle of the two tangents, we shall have

$$\cos \delta = \frac{dx}{ds} \cdot \frac{dx_1}{ds_1} + \frac{dy}{ds} \cdot \frac{dy_1}{ds_1} + \frac{dz}{ds} \cdot \frac{dz_1}{ds_1} = \frac{dx \cdot dx_1 + dy \cdot dy_1 + dz \cdot dz_1}{ds \cdot ds_1}$$

If the two tangents are parallel, we have $\frac{dx}{ds} = \frac{dx_1}{ds_1}, \frac{dy}{ds} = \frac{dy_1}{ds_1}, \frac{dz}{ds} = \frac{dz_1}{ds_1}$, or $\frac{dx}{dx_1} = \frac{dy}{dy_1} = \frac{dz}{dz_1} = \frac{ds}{ds_1}$;

and if they are perpendicular, $dx dx_1 + dy dy_1 + dz dz_1 = 0$. When two curves have a common point they are said to form the same angle as their tangents at that point. They are said to be normal to each other when the angle of their tangents is a right angle, and that they are tangent to each other when that angle is equal to nothing, that is when their tangents at that point coincide. In the first case the coordinates of the point common

to the curve must verify the equation $1 + \frac{dy}{dx} \cdot \frac{dy_1}{dx_1} + \frac{dz}{dx} \cdot \frac{dz_1}{dx_1} = 0$, and in the second case the two equations $\frac{dy_1}{dx_1} = \frac{dy}{dx}, \frac{dz_1}{dx_1} = \frac{dz}{dx}$. Hence if x be the abscissa of the point common to the curve, when they will be tangent the values of y and z , and $\frac{dy}{dx}, \frac{dz}{dx}$, corresponding to that abscissa, must be the same for both curves.

(348.) We shall now proceed to demonstrate a theorem of great use in the theory of the contact of curves. It may be stated in the following manner. Two curves which are tangent to each other being given, if from the point of contact we take upon each of these curves, produced in the same direction, two very small and equal lengths, the straight line joining the extremities of these lengths will sensibly be perpendicular to the tangent, common to the two curves at the point where they meet.

Let the coordinates of the extremities of these equal lengths be, for the first curve (x, y, z) , and for the second (x_1, y_1, z_1) ; let also s and s_1 designate respectively the length of an arc of the first curve contained between a point chosen on this curve and the point (x, y, z) , and the length of an arc of the second curve contained between a point of that curve and the point (x_1, y_1, z_1) . If the coordinates x, y, z, x_1, y_1, z_1 , are made to vary simultaneously, then the difference $s_1 - s$ will remain a constant quantity, and therefore we shall have $ds_1 = ds$.

Let α, β, γ , be the cosines of the angles which the tangent, common to both curves, makes with the three axes, let l be the length of the line joining the two points $(x, y, z), (x_1, y_1, z_1)$, and λ, μ, ν the cosines of the angles it makes with the axis. We shall have

$$\cos \alpha = \frac{dx}{ds} = \frac{dx_1}{ds_1}, \cos \beta = \frac{dy}{ds} = \frac{dy_1}{ds_1}, \cos \gamma = \frac{dz}{ds} = \frac{dz_1}{ds_1}, \text{ and } l = \sqrt{(x - x_1)^2 + (y - y_1)^2 + (z - z_1)^2},$$

$$\cos \lambda = \frac{x - x_1}{l}, \cos \mu = \frac{y - y_1}{l}, \cos \nu = \frac{z - z_1}{l}. \text{ But since } ds = ds_1, \text{ we have also}$$

$$dx^2 + dy^2 + dz^2 = dx_1^2 + dy_1^2 + dz_1^2, \text{ or } (dx + dx_1)(dx - dx_1) + (dy + dy_1)(dy - dy_1) + (dz + dz_1)(dz - dz_1) = 0.$$

From the above values of $\cos \alpha, \cos \beta, \cos \gamma$, we derive also

$$\frac{dx + dx_1}{\cos \alpha} = \frac{dy + dy_1}{\cos \beta} = \frac{dz + dz_1}{\cos \gamma} = ds + ds_1 = 2ds.$$

If, moreover, we observe, that the quantities $x - x_1, y - y_1, z - z_1$, and l are equal to nothing at the point of contact, we shall conclude, that for values of the coordinates differing but very little from those of that point, the ratios of these functions are very nearly equal to the ratios of their differentials. Therefore the following equations will be very nearly exact.

$$\cos \lambda = \frac{x - x_1}{l} = \frac{dx - dx_1}{dl}, \cos \mu = \frac{y - y_1}{l} = \frac{dy - dy_1}{dl}, \cos \nu = \frac{z - z_1}{l} = \frac{dz - dz_1}{dl}.$$

Thus we have very nearly $dx - dx_1 = dl \cos \lambda, dy - dy_1 = dl \cos \mu, dz - dz_1 = dl \cos \nu$, but we have found $dx + dx_1 = 2ds \cos \alpha, dy + dy_1 = 2ds \cos \beta, dz + dz_1 = 2ds \cos \gamma$. Hence by multiplication and addition we shall get

$$(dx - dx_1)(dx + dx_1) + (dy - dy_1)(dy + dy_1) + (dz - dz_1)(dz + dz_1) = 2dl \cdot ds (\cos \alpha \cos \lambda + \cos \beta \cos \mu + \cos \gamma \cos \nu).$$

Integral Calculus. The quantity in the first side of this equation has been found equal to nothing, therefore we shall have very nearly Part III.
 $\cos \alpha \cos \lambda + \cos \beta \cos \mu + \cos \gamma \cos \nu = 0$, that is to say that the tangent, common to the two curves, is very nearly perpendicular to the line joining the two points (x, y, z) , (x_1, y_1, z_1) .

(349.) It is clear that in the preceding theorem, instead of one of the two curves we might take the tangent to the other, and consequently, if from the point of contact we take upon a curve and its tangent, produced in the same direction, two equal and very small lengths, the straight line joining the extremities of these lengths will very nearly be perpendicular to the tangent, that is to say to the normal plane. Let i represent the very small lengths taken upon the curve and tangent, the less i is, the nearer is the line joining the extremities of the tangent and curve to a parallel to a certain normal of the curve. This normal, the direction of which is the limit of the direction of the line of junction, has been designated by the name of the *principal normal*; its equations may be found in the following manner.

Let x, y, z be the coordinates of the point of the curve through which the tangent passes. Let s be the arc reckoned on the curve between the point (x, y, z) , and another point situated in such a manner that the length i should be the producement of the arc s . Let α, β, γ be the angles which the tangent, at the point (x, y, z) , and produced in the same direction as the arc s makes with the three coordinate axes. If we take the arc s for the independent variable, the extremity of the length i , on the curve, will obviously have for its coordinates the three expressions

$$x + i \frac{dx}{ds} + \frac{i^2}{2} \left(\frac{d^2x}{ds^2} + I \right), \quad y + i \frac{dy}{ds} + \frac{i^2}{2} \left(\frac{d^2y}{ds^2} + J \right), \quad z + i \frac{dz}{ds} + \frac{i^2}{2} \left(\frac{d^2z}{ds^2} + K \right),$$

where I, J, K are quantities which vanish when $i = 0$. In the same manner the coordinates of the extremity of the length i , on the tangent, will be

$$x + i \cos \alpha = x + i \frac{dx}{ds}, \quad y + i \cos \beta = y + i \frac{dy}{ds}, \quad z + i \cos \gamma = z + i \frac{dz}{ds}.$$

This understood, if we call k the distance of the two extremities, and λ, μ, ν the angles formed by the line joining them with the coordinate axis, we shall have clearly

$$k = \frac{i^2}{2} \sqrt{\left(\frac{d^2x}{ds^2} + I \right)^2 + \left(\frac{d^2y}{ds^2} + J \right)^2 + \left(\frac{d^2z}{ds^2} + K \right)^2},$$

$$\cos \lambda = \frac{\frac{i^2}{2} \left(\frac{d^2x}{ds^2} + I \right)}{k}, \quad \cos \mu = \frac{\frac{i^2}{2} \left(\frac{d^2y}{ds^2} + J \right)}{k}, \quad \cos \nu = \frac{\frac{i^2}{2} \left(\frac{d^2z}{ds^2} + K \right)}{k},$$

and, consequently,

$$\frac{\cos \lambda}{\frac{d^2x}{ds^2} + I} = \frac{\cos \mu}{\frac{d^2y}{ds^2} + J} = \frac{\cos \nu}{\frac{d^2z}{ds^2} + K} = \frac{1}{\sqrt{\left(\frac{d^2x}{ds^2} + I \right)^2 + \left(\frac{d^2y}{ds^2} + J \right)^2 + \left(\frac{d^2z}{ds^2} + K \right)^2}}.$$

If now we suppose i to converge towards the limit zero, the values of I, J, K will decrease indefinitely, and at the limit we shall have

$$\frac{\cos \lambda}{\frac{d^2x}{ds^2}} = \frac{\cos \mu}{\frac{d^2y}{ds^2}} = \frac{\cos \nu}{\frac{d^2z}{ds^2}} = \frac{1}{\sqrt{\left(\frac{d^2x}{ds^2} \right)^2 + \left(\frac{d^2y}{ds^2} \right)^2 + \left(\frac{d^2z}{ds^2} \right)^2}}.$$

or, what is the same thing,

$$\frac{\cos \lambda}{\frac{d^2x}{ds^2}} = \frac{\cos \mu}{\frac{d^2y}{ds^2}} = \frac{\cos \nu}{\frac{d^2z}{ds^2}} = \frac{\pm 1}{\sqrt{\left(\frac{d^2x}{ds^2} \right)^2 + \left(\frac{d^2y}{ds^2} \right)^2 + \left(\frac{d^2z}{ds^2} \right)^2}}.$$

It would be very easy to verify that the line passing through the point (x, y, z) and forming with the coordinate axis angles determined by the above formulæ, is one of the normals passing through that point. For if we differentiate the equation $ds^2 = dx^2 + dy^2 + dz^2$, in considering s as the independent variable, we shall find $dx \frac{d^2x}{ds^2} + dy \frac{d^2y}{ds^2} + dz \frac{d^2z}{ds^2} = 0$, which is the same thing as $\cos \alpha \cos \lambda + \cos \beta \cos \mu + \cos \gamma \cos \nu = 0$, α, β, γ being the angles with the tangent to the curve, at the point (x, y, z) makes with the axis.

The angles λ, μ, ν , being once determined by means of the above formulæ, it is clear that the equation of the principal normal will be, in representing by x_1, y_1, z_1 the coordinates of any point of that line,

$$\frac{x_1 - x}{\cos \lambda} = \frac{y_1 - y}{\cos \mu} = \frac{z_1 - z}{\cos \nu},$$

or in supposing that s is taken for the independent variable,

$$\frac{x_1 - x}{\frac{d^2x}{ds^2}} = \frac{y_1 - y}{\frac{d^2y}{ds^2}} = \frac{z_1 - z}{\frac{d^2z}{ds^2}}$$

and if s were not taken for the independent variable,

$$\frac{x_1 - x}{d \cdot \left(\frac{dx}{ds} \right)} = \frac{y_1 - y}{d \cdot \left(\frac{dy}{ds} \right)} = \frac{z_1 - z}{d \cdot \left(\frac{dz}{ds} \right)}.$$

(350.) When two curve surfaces have a common point, they are supposed to form, at that point, the same angle as their tangent planes. Two surfaces in particular are said to be normal to each other when their tangent planes are perpendicular to each other, and they are said to be *tangent* or to *touch* each other when these planes coincide. In the last case the normals coincide also. This understood, let $u = 0$, $v = 0$, be the equations of two surfaces referred to three rectangular axes, and touch each other at the point (x, y, z) . Then it is obvious from what precedes that we shall have

$$\frac{du}{dx} : \frac{dv}{dx} :: \frac{du}{dy} : \frac{dv}{dy} :: \frac{du}{dz} : \frac{dv}{dz}.$$

Reciprocally, if this condition be satisfied for the point (x, y, z) , they will have at that point a common normal and be tangent to each other.

If the equations of the two surfaces were resolved with respect to z , their differential equations would be of the form $dz = p dx + q dy$. Then the two surfaces would be tangent to each other, if in the passage of the first to the second, the two quantities p and q preserved the same values.

On the Osculating Plane of a Curve of Double Curvature.

(351.) Let us consider upon a given curve any point P , and let us conceive that a tangent to the curve has been drawn through that point. The plane passing through that tangent and the principal normal, deserves a particular notice, and is called the *osculating plane* of the curve. To obtain this plane, it is sufficient to draw a tangent plane to the curve through the point P , and containing, at the same time, a second point Q of the curve, and to find the position of this plane when the second point approaches indefinitely to the first. Let i be the length of the arc PQ comprised between the two points, and let us suppose that the tangent being produced on the same side as the arc PQ , the extremity of the length i upon the tangent is a point R . The straight line QR , contained in the plane passing through the tangent and the point Q , will be for very small values of i very nearly parallel to the principal normal, therefore this plane will approach, for decreasing values of i , nearer and nearer to coincide with the osculating plane.

Let, as before, α, β, γ represent the angles which the tangent to the curve makes with the axis, and λ, μ, ν those which the principal normal makes with the same lines. Let us suppose besides that the arc s is taken for the independent variable. If x, y, z are the coordinates of P , we shall have

$$\frac{\cos \alpha}{dx} = \frac{\cos \beta}{dy} = \frac{\cos \gamma}{dz}, \text{ and } \frac{\cos \lambda}{d^2 x} = \frac{\cos \mu}{d^2 y} = \frac{\cos \nu}{d^2 z}.$$

This understood, let us imagine that through the point (x, y, z) we draw a line perpendicular to the osculating plane. This line will be at the same time perpendicular to the tangent, and to the principal normal. Therefore, if we call l, m, n the angles it forms with the coordinate axis, we shall have the two equations

$$\cos \alpha \cos l + \cos \beta \cos m + \cos \gamma \cos n = 0, \quad \cos \lambda \cos l + \cos \mu \cos m + \cos \nu \cos n = 0,$$

which the above formulæ will reduce to

$$\cos l \cdot dx + \cos m \cdot dy + \cos n \cdot dz = 0, \quad \cos l \cdot d^2 x + \cos m \cdot d^2 y + \cos n \cdot d^2 z = 0.$$

These last equations may be replaced by the formula

$$\frac{\cos l}{dy d^2 z - dz d^2 y} = \frac{\cos m}{dz d^2 x - dx d^2 z} = \frac{\cos n}{dx d^2 y - dy d^2 x}.$$

And since $\cos^2 l + \cos^2 m + \cos^2 n = 1$, we have

$$\frac{\cos l}{dy d^2 z - dz d^2 y} = \frac{\cos m}{dz d^2 x - dx d^2 z} = \frac{\cos n}{dx d^2 y - dy d^2 x} = \pm 1$$

$$= \frac{\pm 1}{\sqrt{\{(dy d^2 z - dz d^2 y)^2 + (dz d^2 x - dx d^2 z)^2 + (dx d^2 y - dy d^2 x)^2\}}} \\ = \frac{\pm 1}{\sqrt{\{(dx^2 + dy^2 + dz^2)((d^2 x)^2 + (d^2 y)^2 + (d^2 z)^2) - (dx d^2 x + dy d^2 y + dz d^2 z)^2\}}}.$$

If, moreover, we recollect, that $dx^2 + dy^2 + dz^2 = ds^2$, and $dx d^2 x + dy d^2 y + dz d^2 z = 0$, we shall find

$$\frac{\cos l}{dy d^2 z - dz d^2 y} = \frac{\cos m}{dz d^2 x - dx d^2 z} = \frac{\cos n}{dx d^2 y - dy d^2 x} = \frac{\pm 1}{ds \sqrt{\{(d^2 x)^2 + (d^2 y)^2 + (d^2 z)^2\}}}.$$

It is not useless to remark, that for the relations we have found, may be substituted the following:

$$\frac{\cos l}{dy^2 \cdot d\left(\frac{dz}{dy}\right)} = \frac{\cos m}{dz^2 \cdot d\left(\frac{dx}{dz}\right)} = \frac{\cos n}{dx^2 \cdot d\left(\frac{dy}{dx}\right)}, \text{ or}$$

$$\frac{\cos l}{\cos \beta \cdot d \cos \gamma - \cos \gamma \cdot d \cos \beta} = \frac{\cos m}{\cos \gamma \cdot d \cos \alpha - \cos \alpha \cdot d \cos \gamma} = \frac{\cos n}{\cos \alpha \cdot d \cos \beta - \cos \beta \cdot d \cos \alpha}.$$

These last equations are obtained by remarking that since $\cos \alpha = \frac{dx}{ds}$, $\cos \beta = \frac{dy}{ds}$, $\cos \gamma = \frac{dz}{ds}$, we have

Integral Calculus. $\frac{d \cos \alpha}{ds} = \frac{d^2 x}{ds^2}, \frac{d \cos \beta}{ds} = \frac{d^2 y}{ds^2}, \frac{d \cos \gamma}{ds} = \frac{d^2 z}{ds^2}$. But we have also $\frac{\cos \lambda}{d^2 x} = \frac{\cos \mu}{d^2 y} = \frac{\cos \nu}{d^2 z}$, therefore $\frac{\cos \lambda}{d \cos \alpha} = \frac{\cos \mu}{d \cos \beta} = \frac{\cos \nu}{d \cos \gamma}$. These equations combined with the two $\cos \alpha \cos l + \cos \beta \cos m + \cos \gamma \cos n = 0$,

$\cos \lambda \cos l + \cos \mu \cos m + \cos \nu \cos n = 0$ lead obviously to those above. They may also be found in a different way. Let l, m, n designate the angles formed by the coordinate axis with a line perpendicular to a plane, which passing through the tangent at the point (x, y, z) is at the same time parallel to a tangent at a point placed at a very small distance from the point (x, y, z) . Let also $\Delta x, \Delta y, \Delta z, \Delta \cos \alpha, \Delta \cos \beta, \Delta \cos \gamma$, be the increments which the quantities $x, y, z, \cos \alpha, \cos \beta, \cos \gamma$, take in passing from one point to the other. In this case, the values of l, m, n will clearly be obtained by means of the following equations

$$\cos \alpha \cos l + \cos \beta \cos m + \cos \gamma \cos n = 0, (\cos \alpha + \Delta \cos \alpha) \cos l + (\cos \beta + \Delta \cos \beta) \cos m + (\cos \gamma + \Delta \cos \gamma) \cos n = 0.$$

The last, in consequence of the first, is reduced to $\Delta \cos \alpha \cos l + \Delta \cos \beta \cos m + \Delta \cos \gamma \cos n = 0$. But if the second point approaches indefinitely to the first, the differences $\Delta \cos \alpha, \Delta \cos \beta, \Delta \cos \gamma$, will sensibly be proportional to the differential $d \cos \alpha, d \cos \beta, d \cos \gamma$. Therefore at the limit we shall have $\cos l \cdot d \cos \alpha + \cos m \cdot d \cos \beta + \cos n \cdot d \cos \gamma = 0$, and this combined with $\cos \alpha \cos l + \cos \beta \cos m + \cos \gamma \cos n = 0$, will give as above

$$\frac{\cos l}{\cos \beta \cdot d \cos \alpha - \cos \alpha \cdot d \cos \beta} = \frac{\cos m}{\cos \gamma \cdot d \cos \alpha - \cos \alpha \cdot d \cos \gamma} = \frac{\cos n}{\cos \alpha \cdot d \cos \beta - \cos \beta \cdot d \cos \alpha}.$$

Hence the angles l, m, n determined in the last hypothesis, are equal to the angles l, m, n determined in the first. Therefore the plane which contains the tangent at the point (x, y, z) , and which is at the same time parallel to a tangent drawn through a point infinitely near the first, coincides with the osculating plane.

If the arc s were not taken for the independent variable, some of the formulæ found in this paragraph would be no longer exact. For instance, we have then $dx d^2 x + dy d^2 y + dz d^2 z = ds d^2 s$ and not equal to nothing. Consequently, in this case,

$$\frac{\cos l}{dy d^2 z - dz d^2 y} = \frac{\cos m}{dz d^2 x - dx d^2 z} = \frac{\cos n}{dx d^2 y - dy d^2 x} = \frac{\pm 1}{ds \sqrt{\{(d^2 x)^2 + (d^2 y)^2 + (d^2 z)^2 - (d^2 s)^2\}}}.$$

In the particular case where x is taken for the independent variable, if y', z', y'', z'' designate the differential coefficients of the first and second order of y and z , the preceding formula becomes

$$\frac{\cos l}{y' z'' - z' y''} = \frac{\cos m}{-z''} = \frac{\cos n}{y''} = \frac{\pm 1}{\sqrt{\{y''^2 + z''^2 + (y' z'' - z' y'')^2\}}}.$$

(352.) The angles l, m , and n being once determined it becomes easy to obtain the equation of the osculating plane. If we represent by x_1, y_1 , and z_1 , the coordinates of any point of that plane, we shall have for that equation

$$(x_1 - x) \cos l + (y_1 - y) \cos m + (z_1 - z) \cos n = 0,$$

or by substituting for $\cos l, \cos m, \cos n$, the values we have found,

$$(x_1 - x) (dy d^2 z - dz d^2 y) + (y_1 - y) (dz d^2 x - dx d^2 z) + (z_1 - z) (dx d^2 y - dy d^2 x) = 0.$$

If x were considered as the independent variable, the equation of the osculating plane would be

$$(x_1 - x) (y' z'' - z' y'') - z'' (y_1 - y) + y'' (x_1 - x) = 0.$$

(353.) Let us represent by Δs , the increment which the variable s takes when the coordinates x, y, z become $x + \Delta x, y + \Delta y, z + \Delta z$. The angle of the two tangents drawn through the extremities of the arc Δs is called the *angle of contingence*. Let us designate by ω that angle, and by Ω the infinitely small angle formed by the two osculating planes which correspond to the same extremities of the arc, or, what is the same thing, by the perpendiculars to these planes. The quantities ω and Ω will be equal to nothing, the first when the proposed curve is changed to a straight line, and the second when it is a plane curve. But, in general, ω and Ω will have

finite values, as well as the limits of the ratios $\frac{\omega}{\Delta s}, \frac{\Omega}{\Delta s}$, when Δs decreases indefinitely. These limits, which will

be equal if the curve be plane, the one to the curvature of the curve, and the other to nothing, will be used to measure in every case what may be called the *first* and *second* curvature of the proposed curve. It is in consequence of these two curvatures that a curve which is not entirely contained in one plane is called a curve of *double curvature*.

If we represent by $\frac{1}{\rho}$ and $\frac{1}{r}$ these two curvatures ρ and r will be the radii of two circles which will have the same curvatures, and we shall have according to what precedes

$$\frac{1}{\rho} = \lim \left(\frac{\omega}{\Delta s} \right), \quad \frac{1}{r} = \lim \left(\frac{\Omega}{\Delta s} \right).$$

When the arc Δs is very small, its chord $\sqrt{(\Delta x)^2 + (\Delta y)^2 + (\Delta z)^2}$ is very nearly perpendicular to the two normal planes to the curve drawn through the points, the coordinates of which are (x, y, z) and $(x + \Delta x, y + \Delta y, z + \Delta z)$; and the shortest distance between the point (x, y, z) and the line of intersection of the two planes is very nearly equal to the radius ρ . Let ρ_1 be this shortest distance. If we conceive a plane passing through the length ρ_1 , and at the same time perpendicular to the two normal planes, the chord $\sqrt{(\Delta x)^2 + (\Delta y)^2 + (\Delta z)^2}$ will form a very small angle with that plane; that is to say, that it will form a very small angle with its projection on that plane. Hence this projection will be equal to the chord multiplied by a cosine very nearly

Integral
Calculus.

equal to one, and therefore may be represented by a product such as $(1 - i) \sqrt{(\Delta x^2 + \Delta y^2 + \Delta z^2)}$, i designating an infinitely small quantity. Moreover in the triangle formed by the length ρ_1 , and by the projection of the chord, the angle opposite to the side ρ_1 will be very nearly a right angle, and the angle opposite to the projection of the chord will be precisely the angle of the normal planes, that is the angle ω formed by the tangents drawn through the extremities of the arc Δs . We shall have, therefore,

$$\frac{\sin\left(\frac{\pi}{2} + \epsilon\right)}{\rho_1} = \frac{\sin \omega}{(1 - i) \sqrt{(\Delta x^2 + \Delta y^2 + \Delta z^2)}} = \frac{\sin \omega}{(1 - i) \omega} \cdot \frac{\Delta s}{\sqrt{(\Delta x^2 + \Delta y^2 + \Delta z^2)}} \cdot \frac{\omega}{\Delta s}$$

where ϵ is supposed to be an infinitely small number. Hence at the limit we shall find $\frac{1}{\lim \rho_1} = \lim \frac{\omega}{\Delta s} = \frac{1}{\rho}$, or $\lim \rho_1 = \rho$.

It is necessary to remark that the osculating plane passing through the point (x, y, z) being very nearly parallel to the tangent drawn through the point $x + \Delta x, y + \Delta y, z + \Delta z$, will also be very nearly perpendicular to the two normal planes drawn through the extremities of the arc Δs , and to their line of intersection. Therefore the normal which is perpendicular to this line of intersection, will very nearly coincide with the normal situated in the osculating plane, that is to say with the principal normal. From this remark, and from what has been said above, it follows obviously that, in order to obtain the radius ρ , it is sufficient to draw the principal normal corresponding to the point (x, y, z) , and to find the portion of the length of this line contained between the point (x, y, z) and a normal plane infinitely near to the line itself. The radius ρ , measured in this manner, on the principal normal, is what has been called the *radius of curvature* of the proposed curve, relative to the point (x, y, z) ; and the *centre of curvature* is that extremity of the radius of curvature which may be considered as the point where the principal normal, and a normal plane very near it meet. The circle which has for centre this last point, and for radius the radius of curvature, is called circle of curvature, or osculating circle. It touches the proposed curve, and has the same curvature. We may add that, if by the tangent at the point (x, y, z) and by the perpendicular to the osculating plane, we conceive a new plane to pass, the centre of curvature will obviously be situated, with respect to the new plane on the same side as the point $(x + \Delta x, y + \Delta y, z + \Delta z)$, and consequently this centre will always coincide with one of the points of the line the direction of which is determined by the angles λ, μ, ν which verify the formulæ of (349.)

(354.) If in the value of $\frac{1}{\rho}$, found above, we replace the infinitely small quantity ω by the angles α, β, γ , or rather by the differentials of their cosines, it will be sufficient to use the following formulæ:

$$\cos \omega = \cos \alpha (\cos \alpha + \Delta \cos \alpha) + \cos \beta (\cos \beta + \Delta \cos \beta) + \cos \gamma (\cos \gamma + \Delta \cos \gamma),$$

$$1 = \cos^2 \alpha + \cos^2 \beta + \cos^2 \gamma, \quad 1 = (\cos \alpha + \Delta \cos \alpha)^2 + (\cos \beta + \Delta \cos \beta)^2 + (\cos \gamma + \Delta \cos \gamma)^2;$$

from which we get

$$2(1 - \cos \omega) = \cos^2 \alpha - 2 \cos \alpha (\cos \alpha + \Delta \cos \alpha) + (\cos \alpha + \Delta \cos \alpha)^2 + \cos^2 \beta - 2 \cos \beta (\cos \beta + \Delta \cos \beta) + (\cos \beta + \Delta \cos \beta)^2 + \cos^2 \gamma - 2 \cos \gamma (\cos \gamma + \Delta \cos \gamma) + (\cos \gamma + \Delta \cos \gamma)^2,$$

or which is the same thing, $\left(2 \sin \frac{\omega}{2}\right)^2 = (\Delta \cos \alpha)^2 + (\Delta \cos \beta)^2 + (\Delta \cos \gamma)^2$. Dividing by Δs^2 both sides of this last equation, we shall get

$$\left(\frac{\sin \frac{1}{2} \omega}{\frac{1}{2} \omega}\right)^2 \left(\frac{\omega}{\Delta s}\right)^2 = \left(\frac{\Delta \cos \alpha}{\Delta s}\right)^2 + \left(\frac{\Delta \cos \beta}{\Delta s}\right)^2 + \left(\frac{\Delta \cos \gamma}{\Delta s}\right)^2.$$

Then if we suppose that Δs converges towards a limit equal to nothing, we shall find at the limit

$$\frac{1}{\rho} = \sqrt{\left\{\left(\frac{d \cos \alpha}{d s}\right)^2 + \left(\frac{d \cos \beta}{d s}\right)^2 + \left(\frac{d \cos \gamma}{d s}\right)^2\right\}}.$$

In quite a similar manner, it might be proved that the equation $\frac{1}{r} = \lim \left(\frac{\Omega}{\Delta s}\right)$ leads to

$$\frac{1}{r} = \sqrt{\left\{\left(\frac{d \cos l}{d s}\right)^2 + \left(\frac{d \cos m}{d s}\right)^2 + \left(\frac{d \cos n}{d s}\right)^2\right\}}.$$

From these formulæ it obviously results that the first curvature $\frac{1}{\rho}$ is generally equal to nothing when the angles

α, β, γ become constant, and the second curvature $\frac{1}{r}$, when the angles l, m, n are constant. If in the value of $\frac{1}{\rho}$ we substitute for the cosines of α, β, γ their values, we shall have

$$\frac{1}{\rho} = \sqrt{\left\{\left(\frac{d \cdot \left(\frac{d x}{d s}\right)}{d s}\right)^2 + \left(\frac{d \cdot \left(\frac{d y}{d s}\right)}{d s}\right)^2 + \left(\frac{d \cdot \left(\frac{d z}{d s}\right)}{d s}\right)^2\right\}} \quad \text{and developing, and observing that } dx^2 + dy^2 + dz^2 = ds^2$$

Integral Calculus. $= ds d^2s$, we find $\frac{1}{\rho} = \frac{\sqrt{((d^2x)^2 + (d^2y)^2 + (d^2z)^2 - (d^2s)^2)}}{ds^2}$, or again,

$$\frac{1}{\rho} = \frac{\left[\frac{(dx^2 + dy^2 + dz^2) \{ (d^2x)^2 + (d^2y)^2 + (d^2z)^2 \} - (dx d^2x + dy d^2y + dz d^2z)^2}{ds^3} \right]^{\frac{1}{2}}}{\sqrt{\{ (dy d^2z - dz d^2y)^2 + (dz d^2x - dx d^2z)^2 + (dx d^2y - dy d^2x)^2 \}}}{(dx^2 + dy^2 + dz^2)^{\frac{3}{2}}}.$$

If s is the independent variable, we have simply

$$\frac{1}{\rho} = \frac{\sqrt{\{ (d^2x)^2 + (d^2y)^2 + (d^2z)^2 \}}}{ds^2}.$$

But if we take x for the independent variable, we find

$$\frac{1}{\rho} = \frac{(y' z'' - y'' z')^2 + z'^2 + y'^2}{(1 + y'^2 + z'^2)^{\frac{3}{2}}}.$$

And, finally, if from the point (x, y, z) we take on the curve and on the tangent produced in the same direction, two equal and infinitely small lengths represented by i , and if we call κ the distance between the extremities of these two lengths, we shall have, according to what has been proved (349.),

$$\sqrt{\left\{ \left(\frac{d^2x}{ds^2} \right)^2 + \left(\frac{d^2y}{ds^2} \right)^2 + \left(\frac{d^2z}{ds^2} \right)^2 \right\}} = \lim \frac{2\kappa}{i^2},$$

s being the independent variable. Hence, since we have found $\frac{1}{\rho} = \frac{\sqrt{\{ (d^2x)^2 + (d^2y)^2 + (d^2z)^2 \}}}{ds^2}$, we shall have $\rho = \lim \frac{i^2}{2\kappa}$. Therefore to obtain the radius of curvature of a curve in a given point, it is sufficient to take

upon this curve and its tangent, produced in the same direction, two equal and infinitely small lengths, and to divide the square of one of them by the double of the distance between their extremities. The limit of the quotient is the exact value of the radius of curvature.

If we suppose that the plane of (x, y) becomes parallel to the osculating plane, the values of $\cos l$ and $\cos m$ will vanish while those of $\cos n$ will become equal to ± 1 . Then we shall have $dz = 0$, $d^2z = 0$, and

$$\frac{1}{\rho} = \frac{dx d^2y - dy d^2x}{(dx^2 + dy^2)^{\frac{3}{2}}}. \text{ This value is precisely the same as we have obtained before for the radius of curvature}$$

of a plane curve, and it proves, therefore, that the radius of curvature of a curve in space is the same, with respect to its magnitude and direction, as the radius of curvature of the projection of the curve on the osculating plane.

The remarks which have been made with respect to the radius of curvature of plane curves, may obviously be extended to any curve whatever, and it may happen that for certain points situated upon a curve of double curvature, the radius of curvature should become nothing or infinite, or change suddenly its value. The second case will occur whenever the projection of the curve on the osculating plane has a point of contrary flexure.

(355.) We shall now apply the preceding formulæ to a particular case, and we shall take for an example the helix represented by the equations

$$x = r \cos p, \quad y = r \sin p, \quad z = arp.$$

Let us take p for the independent variable, we shall find

$$dx = -r \sin p dp, \quad dy = r \cos p dp, \quad dz = ar dp, \quad d^2x = -r \cos p dp^2, \quad d^2y = -r \sin p dp^2, \quad d^2z = 0,$$

or, which is the same thing,

$$\frac{dx}{-\sin p} = \frac{dy}{\cos p} = \frac{dz}{a} = r dp, \quad \frac{d^2x}{\cos p} = \frac{d^2y}{\sin p} = \frac{d^2z}{0} = -r dp^2.$$

Hence

$$ds = \pm (1 + a^2)^{\frac{1}{2}} r dp, \quad d^2s = 0, \quad \text{and} \quad \frac{\cos \alpha}{-\sin p} = \frac{\cos \beta}{\cos p} = \frac{\cos \gamma}{a} = \pm \frac{1}{\sqrt{1 + a^2}}.$$

Since $d^2s = 0$, whatever be the value of p , it follows that we may employ the formulæ in which the arc s has been taken for the independent variable. Thus we shall have

$$\frac{\cos \lambda}{\cos p} = \frac{\cos \mu}{\sin p} = \frac{\cos \nu}{0} = \pm 1, \quad \text{and} \quad \frac{\cos l}{-a \sin p} = \frac{\cos m}{a \cos p} = \frac{\cos n}{-1} = \pm \frac{1}{\sqrt{1 + a^2}}.$$

We shall find also

$$\frac{1}{\rho} = \frac{1}{\sqrt{1 + a^2}} \left\{ \left(\frac{d \sin p}{ds} \right)^2 + \left(\frac{d \cos p}{ds} \right)^2 \right\}^{\frac{1}{2}} = \pm \frac{1}{\sqrt{1 + a^2}} \frac{dp}{ds} = \frac{1}{(1 + a^2)r}, \text{ and hence } \rho = (1 + a^2)r.$$

Integral
Calculus.

Moreover, the equation of the osculating plane will become

$$a \{ (x_1 - x) \sin p - (y_1 - y) \cos p \} + z_1 - z = 0,$$

which may be written in the following manner, $z_1 - z = a (y_1 \cos p - x_1 \sin p)$. Finally, we shall find, in representing by r_1 the radius of the second curvature which before we have represented by r

$$\frac{1}{r_1} = \frac{a}{\sqrt{(1+a^2)}} \left\{ \left(\frac{d \sin p}{ds} \right)^2 + \left(\frac{d \cos p}{ds} \right)^2 \right\}^{\frac{1}{2}} = \frac{a}{(1+a^2)r}, \text{ and hence } r_1 = \frac{1+a^2}{a} r.$$

If in these formulæ we substitute for the quantity a the angle γ determined by the equation $\cos \gamma = \frac{a}{\sqrt{1+a^2}}$, they become respectively,

$$\frac{\cos l}{\sin p} = \frac{\cos m}{-\cos p} = \frac{\cos n}{\tan \gamma} = \pm \cos \gamma, \quad \rho = \frac{r}{\sin^2 \gamma} = r \operatorname{cosec}^2 \gamma, \quad r_1 = \frac{r}{\sin \gamma \cos \gamma} = 2r \operatorname{cosec} 2\gamma.$$

From the values we have obtained for $\cos \lambda$, $\cos \mu$, $\cos \nu$, it obviously results that the principal normal of the helix, at the point (x, y, z) , coincides with the perpendicular drawn through this point on the axis of z , or which

is the same thing, with the generating line of the surface represented by the equation $z = ar \tan^{-1} \frac{y}{x}$. Hence the

plane which contains this line and the tangent to the helix, or, in other words, the plane which touches that surface at the point (x, y, z) , will coincide with the osculating plane of the helix. This might also be seen by substituting in the equation of the tangent plane to that surface which we have found (342.), $x = r \cos p$, $y = r \sin p$, for then it becomes identical with the equation of the osculating plane we have just found.

The value of the radius of curvature ρ , might also be found by means of the rule given (343.). For that, let us conceive that from the point (x, y, z) , we take on the curve and on its tangent produced in the same direction, two equal and infinitely small lengths designated by i . Let κ be the distance of the extremities of these two lengths, and let us suppose that the first is the point of the helix, the coordinates of which are $x + \Delta x$, $y + \Delta y$, $z + \Delta z$; the second extremity will be on the tangent in a point which will still have for one of its coordinates $z + \Delta z$. Hence the length taken upon the tangent will have for its projection upon the plane of (x, y) , $\tan \gamma \cdot \Delta z$, γ being the angle of that tangent with the axis of z . Let I designate this same projection, since we have, generally, $z = arp$,

$\tan \gamma = \frac{1}{a}$, we shall have also $I = r \Delta p$. Therefore the projection I will be equal to the projection of the arc

Δs , that is to say, to the projection of the length $i = \Delta s$, taken on the helix. The first projection will be reckoned on the tangent to the circle represented by the formula $x^2 + y^2 = r^2$. It is moreover obvious, that the distance κ between two points which have the same z will be parallel to the plane (x, y) , and will not differ from its projection on that plane. Therefore, if, in that same plane, we take from the point (x, y) , on the circle and on its tangent produced in the same direction, two infinitely small lengths equal to i , κ will be the distance of the two extremities of these lengths. This understood, since the radius of curvature of a circle is precisely the radius

of the circle, we shall have, according to a theorem previously demonstrated, $r = \lim \frac{I^2}{2\kappa}$, and $\rho = \lim \frac{i^2}{2\kappa}$,

therefore $\frac{\rho}{r} = \lim \frac{i^2}{I^2}$. But we have just found $i = \Delta s$, $I = r \Delta p$, therefore $\frac{\rho}{r} = \lim \left(\frac{\Delta s}{r \Delta p} \right)^2 = \frac{ds^2}{r^2 dp^2} = 1 + a^2 = \operatorname{cosec}^2 \gamma$ which agrees with the value found above.

Determination of the Centre of Curvature.

(356.) Let, as before, ρ represent the radius of curvature of any curve whatever corresponding to the point (x, y, z) , and let x_1, y_1, z_1 be the coordinates of the extremity of that radius which is called the centre of curvature,

and λ, μ, ν the angles formed by the radius with the three axes, we shall have $\frac{x_1 - x}{\rho} = \cos \lambda$, $\frac{y_1 - y}{\rho} = \cos \mu$,

$\frac{z_1 - z}{\rho} = \cos \nu$, the angles λ, μ , and ν being determined by the formula

$$\frac{\cos \lambda}{\frac{d^2 x}{ds^2}} = \frac{\cos \mu}{\frac{d^2 y}{ds^2}} = \frac{\cos \nu}{\frac{d^2 z}{ds^2}} = \frac{1}{\sqrt{\left\{ \left(\frac{d^2 x}{ds^2} \right)^2 + \left(\frac{d^2 y}{ds^2} \right)^2 + \left(\frac{d^2 z}{ds^2} \right)^2 \right\}}},$$

or, since we have found $\frac{1}{\rho} = \frac{\sqrt{\{ (d^2 x)^2 + (d^2 y)^2 + (d^2 z)^2 \}}}{ds^2}$, by the formula

$$\frac{\cos \lambda}{\frac{d^2 x}{ds^2}} = \frac{\cos \mu}{\frac{d^2 y}{ds^2}} = \frac{\cos \nu}{\frac{d^2 z}{ds^2}} = \frac{\rho}{ds^2}, \text{ from which we get } \cos \lambda = \rho \frac{d^2 x}{ds^2}, \cos \mu = \rho \frac{d^2 y}{ds^2}, \cos \nu = \rho \frac{d^2 z}{ds^2},$$

and, consequently,

$$x_1 - x = \rho^2 \frac{d^2 x}{ds^2}, \quad y_1 - y = \rho^2 \frac{d^2 y}{ds^2}, \quad z_1 - z = \rho^2 \frac{d^2 z}{ds^2}.$$

If s were not taken for the independent variable, it would be necessary to substitute for

$$\frac{d^2 x}{ds^2}, \frac{d^2 y}{ds^2}, \frac{d^2 z}{ds^2}, \text{ the quantities } \frac{d \cdot \left(\frac{dx}{ds} \right)}{ds}, \frac{d \cdot \left(\frac{dy}{ds} \right)}{ds}, \frac{d \cdot \left(\frac{dz}{ds} \right)}{ds},$$

and thus we would have

$$\begin{aligned} \cos \lambda &= \rho \frac{d \left(\frac{dx}{ds} \right)}{ds}, \quad \cos \mu = \rho \frac{d \left(\frac{dy}{ds} \right)}{ds}, \quad \cos \nu = \rho \frac{d \left(\frac{dz}{ds} \right)}{ds}, \\ x_1 - x &= \rho^2 \frac{d \left(\frac{dx}{ds} \right)}{ds}, \quad y_1 - y = \rho^2 \frac{d \left(\frac{dy}{ds} \right)}{ds}, \quad z_1 - z = \rho^2 \frac{d \left(\frac{dz}{ds} \right)}{ds}. \end{aligned}$$

But when s is not taken for the independent variable, we have found

$$\frac{1}{\rho} = \frac{\sqrt{\{ (dy d^2 z - dz d^2 y)^2 + (dz d^2 x - dx d^2 z)^2 + (dx d^2 y - dy d^2 x)^2 \}}}{ds^3},$$

and therefore we shall have

$$\begin{aligned} x_1 - x &= \frac{ds d^2 x - dx d^2 s}{(dy d^2 z - dz d^2 y)^2 + (dz d^2 x - dx d^2 z)^2 + (dx d^2 y - dy d^2 x)^2} ds^3 \\ &= \frac{dy (dy d^2 x - dx d^2 y) + dz (dz d^2 x - dx d^2 z)}{(dy d^2 z - dz d^2 y)^2 + (dz d^2 x - dx d^2 z)^2 + (dx d^2 y - dy d^2 x)^2} (dx^2 + dy^2 + dz^2) \\ y_1 - y &= \frac{ds d^2 y - dy d^2 s}{(dy d^2 z - dz d^2 y)^2 + (dz d^2 x - dx d^2 z)^2 + (dx d^2 y - dy d^2 x)^2} ds^3 \\ &= \frac{dz (dz d^2 y - dy d^2 z) + dx (dx d^2 y - dy d^2 x)}{(dy d^2 z - dz d^2 y)^2 + (dz d^2 x - dx d^2 z)^2 + (dx d^2 y - dy d^2 x)^2} (dx^2 + dy^2 + dz^2) \\ z_1 - z &= \frac{ds d^2 z - dz d^2 s}{(dy d^2 z - dz d^2 y)^2 + (dz d^2 x - dx d^2 z)^2 + (dx d^2 y - dy d^2 x)^2} ds^3 \\ &= \frac{dx (dx d^2 y - dy d^2 x) + dy (dy d^2 z - dz d^2 y)}{(dy d^2 z - dz d^2 y)^2 + (dz d^2 x - dx d^2 z)^2 + (dx d^2 y - dy d^2 x)^2} (dx^2 + dy^2 + dz^2). \end{aligned}$$

In the particular case where x is taken for the independent variable, these formulæ become

$$\begin{aligned} x_1 - x &= - \frac{y' y'' + z' z''}{(1 + y'^2 + z'^2)^{3/2}} \rho^2 = - \frac{y' y'' + z' z''}{(y' z'' - z' y'')^2 + z'^2 + y'^2} (1 + y'^2 + z'^2), \\ y_1 - y &= \frac{z' (z' y'' - y' z'') + y''}{1 + y'^2 + z'^2} \rho^2 = \frac{z' (z' y'' - y' z'') + y''}{(y' z'' - z' y'')^2 + z'^2 + y'^2} (1 + y'^2 + z'^2), \\ z_1 - z &= \frac{y' (y' z'' - y'' z') + z''}{1 + y'^2 + z'^2} \rho^2 = \frac{y' (y' z'' - y'' z') + z''}{(y' z'' - y'' z')^2 + z'^2 + y'^2} (1 + y'^2 + z'^2). \end{aligned}$$

These formulæ will enable us to determine the coordinates of the centre of curvature. These coordinates must also, in general, verify the equations

$$\begin{aligned} (x_1 - x)^2 + (y_1 - y)^2 + (z_1 - z)^2 &= \rho^2, \quad (x_1 - x) dx + (y_1 - y) dy + (z_1 - z) dz = 0, \\ (x_1 - x) d^2 x + (y_1 - y) d^2 y + (z_1 - z) d^2 z - dx^2 - dy^2 - dz^2 &= 0. \end{aligned}$$

The two first are obviously satisfied by the coordinates of all the points situated in the normal plane at a distance ρ from the point (x, y, z) . As to the last equation it may be obtained by multiplying the values of $x_1 - x$, $y_1 - y$, $z_1 - z$, by $d^2 x$, $d^2 y$, and $d^2 z$, and then adding them. It is, moreover, essential to observe, that the second and third equations may be found by differentiating the first and second, in the supposition that x_1 , y_1 , and z_1 , are constant quantities.

(357.) To every point of the curve in space corresponds a centre of curvature, and all these centres form a curve the equations of which will easily be obtained. It will be sufficient for that purpose to express the values of x_1 , y_1 , and z_1 in function of only one variable x , y or s , and then to eliminate that variable between the three values. The two equations resulting from that elimination will only contain the three variables x_1 , y_1 , and z_1 , and will represent the line formed by the centres of curvature of the given curve. To discover the principal properties of this curve, we shall differentiate the two first of the three preceding equations, in considering each of the quantities this curve, we shall find thus $(x_1 - x) dx_1 + (y_1 - y) dy_1 + (z_1 - z) dz_1 = \rho d\rho$, and they contain as a variable. We shall find thus $(x_1 - x) dx_1 + (y_1 - y) dy_1 + (z_1 - z) dz_1 = \rho d\rho$, and $dx dx_1 + dy dy_1 + dz dz_1 = 0$. From the last equation it follows that the tangent drawn to the new curve through the point (x_1, y_1, z_1) forms a right angle with the tangent to the given curve at the point (x, y, z) . Hence the tangent to the new curve is contained in the normal plane to the proposed curve. Moreover if we call

Integral Calculus. s_1 the arc of the new curve, contained between a fixed point and the point (x_1, y_1, z_1) , we shall have $ds_1^2 = dx_1^2 + dy_1^2 + dz_1^2$, and we shall derive from this value, and the first of the two preceding equations, the relation Part III.

$$\frac{d\rho}{ds_1} = \frac{x_1 - x}{\rho} \frac{dx_1}{ds_1} + \frac{y_1 - y}{\rho} \frac{dy_1}{ds_1} + \frac{z_1 - z}{\rho} \frac{dz_1}{ds_1}. \quad \text{This formula shows that the ratio } \frac{d\rho}{ds_1} \text{ is equal to the cosine}$$

of the obtuse or acute angle formed by the radius of curvature ρ with the tangent to the new curve. When the proposed curve is a plane curve, this tangent coincides with the radius of curvature, or with its producement,

and consequently the ratio $\frac{d\rho}{ds_1}$ is reduced to the cosine of an angle equal to nothing or to π , which is ± 1 .

Therefore we have in that case $d\rho = \pm ds$. From this result we may conclude, as we have done before, that in the case of a plane curve the arc Δs_1 is the difference of the radii of curvature corresponding to the two extremities.

But this is no longer true when the curve is not a plane curve, and in that case the ratio $\frac{d\rho}{ds_1}$ obtains a numerical value which generally differs from one.

(358.) Let us conceive now that an inextensible thread, of a known length, is fixed by one of its extremities in a certain point of the proposed curve, and that this thread, first applied on the tangent drawn to the curve through the point to which it is attached, moves in remaining always stretched, so that a part of it is bent on the arc of the curve contained between the fixed point, and the point (x, y, z) that is supposed to move. The extremity of the other part of the thread which will remain straight, and will touch the curve at the point (x, y, z) , will describe a new curve. The given curve is called the *evolute*, and the new curve the *involute*. Their relative properties may be easily established in the following manner.

Let x_1, y_1, z_1 be the coordinates of a point of the involute which corresponds to the point (x, y, z) of the evolute, and g the distance between these two points. We shall have

$$\frac{x_1 - x}{dx} = \frac{y_1 - y}{dy} = \frac{z_1 - z}{dz} = \frac{g}{ds}, \text{ or } \frac{x_1 - x}{dx} = \frac{y_1 - y}{dy} = \frac{z_1 - z}{dz} = -\frac{g}{ds}.$$

The first formula must be used when the length g is reckoned from the point (x, y, z) of the evolute, on the tangent produced in the same direction as the arc s , and the other formula in the contrary case. In the first hypothesis we have $g + s = c$ or $dg = -ds$; and in the second $g - s = c$ or $dg = ds$, c designating a

constant quantity. Hence we shall have in both cases $x_1 - x = -g \frac{dx}{dg}$, $y_1 - y = -g \frac{dy}{dg}$, $z_1 - z = -g \frac{dz}{dg}$.

If we differentiate these last equations, we shall find $dx_1 = -g d\left(\frac{dx}{dg}\right)$, $dy_1 = -g d\left(\frac{dy}{dg}\right)$, $dz_1 = -g d\left(\frac{dz}{dg}\right)$,

and as we have besides $dg^2 = ds^2 = dx^2 + dy^2 + dz^2$, or $\left(\frac{dx}{dg}\right)^2 + \left(\frac{dy}{dg}\right)^2 + \left(\frac{dz}{dg}\right)^2 = 1$, or again $\frac{dx}{dg} \cdot d\left(\frac{dx}{dg}\right) + \frac{dy}{dg} \cdot d\left(\frac{dy}{dg}\right) + \frac{dz}{dg} \cdot d\left(\frac{dz}{dg}\right) = 0$, we shall find by multiplying the values of dx_1, dy_1, dz_1 , respectively by dx, dy, dz , and adding them, $dx dx_1 + dy dy_1 + dz dz_1 = 0$. From this last formula it follows

that the tangents drawn through the points (x_1, y_1, z_1) and (x, y, z) to the involute and evolute are at right angles to each other. Therefore the tangent to the evolute is always normal to the involute. This proposition, which has already been proved for plane curves, is also true for curves of double curvature. When the evolute is known, it is sufficient to obtain the equations of the involute to substitute in the values we have found for $x_1 - x, y_1 - y, z_1 - z$, the values of x, y, z in function of s , to replace g by $c \mp s$, and to eliminate s between the three equations thus obtained.

(359.) Let us suppose now that it is proposed to find not the involute, but an evolute of the curve to which belong the coordinates x, y, z . If we call x_1, y_1, z_1 the coordinates of a point of this evolute, which corresponds to the point (x, y, z) of the given curve, and if we still designate by g the distance between these two points, we shall have by exchanging in the formulæ obtained in the preceding paragraph x, y, z into x_1, y_1 , and z_1 , and

reciprocally, $\frac{x - x_1}{dx_1} = \frac{y - y_1}{dy_1} = \frac{z - z_1}{dz_1} = \frac{-g}{dg}$, and consequently, $dx_1 = \frac{(x_1 - x) dg}{g}$, $dy_1 = \frac{(y_1 - y) dg}{g}$,

$dz_1 = \frac{(z_1 - z) dg}{g}$. Moreover we shall have $(x_1 - x)^2 + (y_1 - y)^2 + (z_1 - z)^2 = g^2$. If we differentiate

three times this last equation, in taking s for the independent variable, and if we make use of the values we have just obtained for dx_1, dy_1, dz_1 , we shall find $(x_1 - x) dx + (y_1 - y) dy + (z_1 - z) dz = 0$, $(x_1 - x) d^2x + (y_1 - y) d^2y + (z_1 - z) d^2z = ds^2$, $(x_1 - x) d(g d^2x) + (y_1 - y) d(g d^2y) + (z_1 - z) d(g d^2z) = 0$; from which we shall conclude

$$\frac{x_1 - x}{dy dg (g d^2z) - dz dg (g d^2y)} = \frac{y_1 - y}{dz dg (g d^2x) - dx dg (g d^2z)} = \frac{z_1 - z}{dx dg (g d^2y) - dy dg (g d^2x)} = \frac{ds^2}{d^3x \{ dy dg (g d^2z) - dz dg (g d^2y) \} + d^3y \{ dz dg (g d^2x) - dx dg (g d^2z) \} + d^3z \{ dx dg (g d^2y) - dy dg (g d^2x) \}}$$

$$\begin{aligned} \text{Integral Calculus.} &= \pm \frac{g}{\sqrt{\{d y d(g d^2 z) - d z d(g d^2 y)\}^2 + \{d z d(g d^2 x) - d x d(g d^2 z)\}^2 + \{d x d(g d^2 y) - d y d(g d^2 x)\}^2}} \\ &= \pm \frac{g}{\sqrt{[d s^2 \{[d(g d^2 x)]^2 + [d(g d^2 y)]^2 + [d(g d^2 z)]^2\} - \{d x d(g d^2 x) + d y d(g d^2 y) + d z d(g d^2 z)\}^2}}. \end{aligned}$$

From this last formula we shall derive by inverting two of the fractions, and raising each of them to the square,

$$\begin{aligned} \frac{d s^2 \{[d(g d^2 x)]^2 + [d(g d^2 y)]^2 + [d(g d^2 z)]^2\} - \{d x d(g d^2 x) + d y d(g d^2 y) + d z d(g d^2 z)\}^2}{g^2} = \\ \frac{g^2}{d s^4} \{d x d^2 y d^3 z - d x d^2 z d^3 y + d y d^2 z d^3 x - d y d^2 x d^3 z + d z d^2 x d^3 y - d z d^2 y d^3 x\}^2, \end{aligned}$$

or which is the same thing

$$\begin{aligned} &\left[\left(\frac{d^2 x}{d s^2}\right)^2 + \left(\frac{d^2 y}{d s^2}\right)^2 + \left(\frac{d^2 z}{d s^2}\right)^2\right] \frac{d g^2}{d s^2} + 2 \left[\frac{d^2 x}{d s^2} \cdot \frac{d^2 y}{d s^2} + \frac{d^2 y}{d s^2} \cdot \frac{d^2 z}{d s^2} + \frac{d^2 z}{d s^2} \cdot \frac{d^2 x}{d s^2}\right] g \frac{d g}{d s} \\ &+ \left[\left(\frac{d^3 x}{d s^3}\right)^2 + \left(\frac{d^3 y}{d s^3}\right)^2 + \left(\frac{d^3 z}{d s^3}\right)^2 - \left(\frac{d x}{d s} \frac{d^3 x}{d s^3} + \frac{d y}{d s} \frac{d^3 y}{d s^3} + \frac{d z}{d s} \frac{d^3 z}{d s^3}\right)^2\right] \\ &g^2 = \frac{(d x d^2 y d^3 z - d x d^2 z d^3 y + d y d^2 z d^3 x - d y d^2 x d^3 z + d z d^2 x d^3 y - d z d^2 y d^3 x) g^4}{d s^3}. \end{aligned}$$

(360.) If in this equation we substitute for x, y, z their values expressed in function of s , it will only contain the variable s and the unknown g , with the differential coefficient $\frac{d g}{d s}$. It will be a differential equation of the first order. The integral will contain an arbitrary constant, and there is therefore an infinite number of functions of s , corresponding to the various values of the arbitrary constant, which satisfy this equation. If, after having determined one of these functions, we substitute in the three equations

$$\begin{aligned} (x_1 - x)^2 + (y_1 - y)^2 + (z_1 - z)^2 &= g^2, \quad (x_1 - x) d x + (y_1 - y) d y + (z_1 - z) d z = 0, \\ (x_1 - x) d^2 x + (y_1 - y) d^2 y + (z_1 - z) d^2 z &= d s^2, \end{aligned}$$

for the quantities x, y, z, g , their values in function of s , we shall have only to eliminate s between these formulæ to obtain between the coordinates x_1, y_1 and z_1 two equations to represent an evolute of the proposed curve. This understood, it is clear that this curve will have an infinite number of evolutes which correspond to the various values of g , or which is the same thing, to the various values of the arbitrary constant. All these evolutes are situated on the surface represented by the equation resulting from the elimination of s between the equations $(x_1 - x) d x + (y_1 - y) d y + (z_1 - z) d z = 0$, $(x_1 - x) d^2 x + (y_1 - y) d^2 y + (z_1 - z) d^2 z = d s^2$. This surface, or the locus of all the evolutes of the proposed curve, possesses some remarkable properties which are easily deduced from the two preceding equations. These may be put under the form

$$(x_1 - x) \frac{d x}{d s} + (y_1 - y) \frac{d y}{d s} + (z_1 - z) \frac{d z}{d s} = 0, \quad (x_1 - x) \frac{d^2 x}{d s^2} + (y_1 - y) \frac{d^2 y}{d s^2} + (z_1 - z) \frac{d^2 z}{d s^2} = 1.$$

First, it is obvious that if we take for s and the quantities which depend upon it, that is to say, for $x, y, z, \frac{d x}{d s}, \frac{d y}{d s}, \frac{d z}{d s}, \frac{d^2 x}{d s^2}, \frac{d^2 y}{d s^2}, \frac{d^2 z}{d s^2}$, determinate values, the two equations above, in which x_1, y_1 , and z_1 will alone remain variables, will represent two planes the common section of which will be a straight line contained in the surface in question. Therefore this surface will contain an infinite number of straight lines corresponding to the various values of s , and will be consequently a *surface réglée*.

It may be observed that the first of the two last equations is precisely that of the normal plane drawn through the point (x, y, z) to the given curve. As to the second equation, it may be transformed by means of the equations

$$\cos \lambda = \rho \frac{d^2 x}{d s^2}, \quad \cos \mu = \rho \frac{d^2 y}{d s^2}, \quad \cos \nu = \rho \frac{d^2 z}{d s^2}, \quad \text{into } (x_1 - x) \cos \lambda + (y_1 - y) \cos \mu + (z_1 - z) \cos \nu = \rho;$$

and then we see immediately that it is satisfied by the values of x_1, y_1 , and z_1 , which belong to the centre of curvature, and that it represents a plane drawn through this same centre perpendicularly to the radius of curvature the direction of which forms with the axis the angles λ, μ , and ν . If we assume $x = \phi(s), y = \chi(s), z = \psi(s)$, the two equations above will become respectively

$$\begin{aligned} \{x_1 - \phi(s)\} \phi'(s) + \{y_1 - \chi(s)\} \chi'(s) + \{z_1 - \psi(s)\} \psi'(s) &= 0, \\ \{x_1 - \phi(s)\} \phi''(s) + \{y_1 - \chi(s)\} \chi''(s) + \{z_1 - \psi(s)\} \psi''(s) &= 1. \end{aligned}$$

The first equation will represent the surface above mentioned if we suppose s to be determined by the second. This understood, it is easy to find the differential equation of the surface. For that let us differentiate the first equation, in considering x, y, z , and s , as variables, then we shall have after reduction, by means of the second equation, and of the relation $(\phi'(s))^2 + (\chi'(s))^2 + (\psi'(s))^2 = 1$, $\phi'(s) d x_1 + \chi'(s) d y_1 + \psi'(s) d z_1 = 0$.

Integral
Calculus.

This equation shows that the normal drawn through the point (x_1, y_1, z_1) to the *surface réglée* makes angles with the axis the cosines of which are proportional to the derived functions $\phi'(s) = \frac{dx}{ds}$, $\chi'(s) = \frac{dy}{ds}$, $\psi'(s) = \frac{dz}{ds}$. Part III.

Therefore this normal and the tangent drawn through the point (x, y, z) to the given curve are two parallel lines. Hence, since the tangent plane drawn through the point (x_1, y_1, z_1) to the *surface réglée* must contain the generating line of this surface, and consequently the centre of curvature of the proposed curve, it will necessarily coincide with the plane drawn through this centre perpendicularly to the two straight lines, that is to say, with the normal plane to the curve. From these observations it follows, that each normal plane to the curve will touch the *surface réglée* at every point of the generating line through which it passes. Hence the surface in question, that is the locus of all the evolutes of the curve, will be a *surface développable*.

It is essential to remark, that the equation $\phi'(s) dx_1 + \chi'(s) dy_1 + \psi'(s) dz_1 = 0$ is the same as the equation $dx dx_1 + dy dy_1 + dz dz_1 = 0$, we have found before, in which for dx , dy , and dz , their values $\phi'(s) ds$, $\chi'(s) ds$, $\psi'(s) ds$, have been substituted.

It is also necessary to observe, that in the case where the variable s is no longer an independent variable, in order to obtain the equation $(x_1 - x) d^2 x + (y_1 - y) d^2 y + (z_1 - z) d^2 z = ds^2$, it is sufficient to differentiate the equation $(x_1 - x) dx + (y_1 - y) dy + (z_1 - z) dz = 0$, and to reduce it, in taking into consideration the equation itself, and the values which have been given for dx_1 , dy_1 , dz_1 . Hence we may infer, that the equation in x_1, y_1, z_1 , resulting from the elimination of s between the two equations just mentioned, will represent in every case the surface which is the locus of all the evolutes of the given curve. And, moreover, as these two equations are identically the same as the two last of the three which we have said are verified by the coordinates of any point of the curve which is the locus of the centres of curvature, it may be affirmed, that this last curve is situated upon the *surface réglée*.

It may be proved easily, and without the help of calculation, that a *surface développable* which is tangent to every normal plane to any given curve, is, at the same time, the locus of all the evolutes of that curve. This, in fact, may be demonstrated by means of the following considerations.

Let us imagine, that the plane tangent to a *surface développable* is made to roll upon this surface, with several straight lines drawn through a point taken at random in this plane, this point will describe a curve and each straight line will draw on the surface an evolute of this curve. Hence the *surface développable* will be the locus of all the evolutes; and the tangent plane which will contain the tangents to the evolutes, or, in other terms, several straight lines normal to the curve described by the point, will necessarily coincide with the normal plane to the curve. If now it is required that the curve described by the point should be a given curve, it will be sufficient to make the *surface développable* to coincide with that which touches every normal plane to the proposed curve, and to choose properly the point.

(361.) To show an application of the preceding formulæ, we shall consider again the helix represented by the equations $x = r \cos p$, $y = r \sin p$, $z = arp$. If we take for the independent variable the arc s , or which is the same thing, the angle p , we shall have

$$dx = -r \sin p dp, \quad dy = r \cos p dp, \quad dz = ar dp, \quad d^2 x = -r \cos p dp^2, \quad d^2 y = -r \sin p dp^2, \quad d^2 z = a dp^2, \\ d^3 x = r \sin p dp^3, \quad d^3 y = -r \cos p dp^3, \quad d^3 z = 0.$$

We have, besides, already found $ds = \pm (1 + a^2)^{\frac{1}{2}} r dp$, $\rho = (1 + a^2) r$. This understood, we shall have for the coordinates of the centre of curvature

$$x_1 = -a^2 r \cos p, \quad y_1 = -a^2 r \sin p, \quad z_1 = arp.$$

If we eliminate p between these last equations, we shall obtain between the coordinates x_1, y_1, z_1 , two equations which will represent the line of the centres of curvatures. We shall have thus for these equations $\frac{y_1}{x_1} = \tan \frac{z_1}{ar}$, $x_1^2 + y_1^2 = a^4 r^2$. Hence it is clear, that this line will be a second helix situated as well as the first on the surface

represented by the equation $\frac{y}{x} = \tan \frac{z}{ar}$, and on a right cylinder having for its base, in the plane x, y , a circle the radius of which is equal to $a^2 r$. This result might have been easily foreseen, since we know that to obtain the centre of curvature corresponding to a point (x, y, z) of the helix, it suffices to take on the generating line of the helicoidal surface, from the point (x, y, z) the length $\rho = (1 + a^2) r$, and consequently from the axis of the cylinder the length $\rho - r = a^2 r$.

The equations which determine the evolute,

$$(x_1 - x)^2 + (y_1 - y)^2 + (z_1 - z)^2 = g^2, \quad (x_1 - x) dx + (y_1 - y) dy + (z_1 - z) dz = 0, \\ (x_1 - x) d^2 x + (y_1 - y) d^2 y + (z_1 - z) d^2 z = ds^2, \quad (x_1 - x) d(g^2 x) + (y_1 - y) d(g^2 y) + (z_1 - z) d(g^2 z) = 0,$$

will become in this example

$$x_1^2 + y_1^2 - 2r(x_1 \cos p + y_1 \sin p) + r^2 + (z_1 - arp)^2 = g^2, \quad x_1 \sin p - y_1 \cos p = a(z_1 - arp), \\ x_1 \cos p + y_1 \sin p = -a^2 r(x_1 \cos p + y_1 \sin p - r) dg + (y_1 \cos p - x_1 \sin p) g dp = 0.$$

If after having raised to the square both sides of the second and third equation, we add them, we find

$$x_1^2 + y_1^2 = a^4 r^2 + a^2 (z_1 - arp)^2, \text{ and consequently, } p = \frac{z_1}{ar} \mp \left\{ \frac{x_1^2 + y_1^2}{a^4 r^2} - 1 \right\}^{\frac{1}{2}}. \text{ Substituting then this value}$$

Integral
Calculus.

Part III.

 of p in the equation $x_1 \cos p + y_1 \sin p = -a^2 r$, we find

$$\left(x_1 \cos \frac{z_1}{ar} + y_1 \sin \frac{z_1}{ar}\right) \cos \left(\frac{x_1^2 + y_1^2}{a^4 r^2} - 1\right)^{\frac{1}{2}} + a^2 r = \pm \left(y_1 \cos \frac{z_1}{ar} - x_1 \sin \frac{z_1}{ar}\right) \sin \left(\frac{x_1^2 + y_1^2}{a^4 r^2} - 1\right)^{\frac{1}{2}}.$$

This last equation, being that which results from the elimination of p , represents the *surface développable* which is tangent to every normal plane to the helix, and which is the locus of all the evolutes of that curve. To obtain the equations of one of these evolutes, it will be sufficient to join to the equation of the *surface développable* that which results from the elimination of p between the two equations $x_1^2 + y_1^2 - 2r(x_1 \cos p + y_1 \sin p) + r^2 + (z_1 - arp)^2 = g^2$,

and $p = \frac{z_1}{ar} \pm \left\{ \frac{x_1^2 + y_1^2}{a^4 r^2} - 1 \right\}^{\frac{1}{2}}$. The first of these two last equations may be replaced in the present case by $\left(\frac{x_1^2 + y_1^2}{a^2} + r^2\right)(1 + a^2) = g^2$, which is obtained by combining it with $x_1^2 + y_1^2 = a^4 r^2 + a^2(z_1 - arp)^2$.

Moreover the differential equation of the first order between s and g will become $\frac{dg^2}{dp^2} + \frac{a^2}{1+a^2} g^2 = \frac{a^2}{(1+a^2)^3} \frac{g^4}{r^2}$,

which, being integrated, gives $\frac{a}{\sqrt{1+a^2}} p \pm \cos^{-1} \frac{r(1+a^2)}{g} = c$, c being an arbitrary constant, and consequently $g = \frac{r(1+a^2)}{\cos\left(c - \frac{ap}{\sqrt{1+a^2}}\right)}$. This value being put in the equation $\left(\frac{x_1^2 + y_1^2}{a^2} + r^2\right)(1+a^2) = g^2$, gives

$$\frac{r(1+a^2)}{\cos\left(c - \frac{ap}{\sqrt{1+a^2}}\right)} = g.$$

after the substitution of the value of p found above

$$\frac{a^2(1+a^2)r^2}{x_1^2 + y_1^2 + a^2 r^2} = \left\{ \cos\left(c - \frac{z_1}{r\sqrt{1+a^2}} \pm \frac{\sqrt{x_1^2 + y_1^2 - a^4 r^2}}{ar\sqrt{1+a^2}}\right) \right\}^2.$$

This equation joined to the equation of the *surface développable* determines for each value of the constant c an evolute of the helix.

It is not useless to remark that the smallest value of g is $r(1+a^2)$, that is to say equal to the radius of curvature, and corresponds to an infinite number of values of the angle p , one of which is clearly $\frac{c\sqrt{1+a^2}}{a}$, for then

$$\cos\left(c - \frac{ap}{\sqrt{1+a^2}}\right) = 1. \text{ If we assume } \frac{c\sqrt{1+a^2}}{a} = p_1, \text{ then we shall have } g = \frac{r(1+a^2)}{\cos\left(\frac{a(p_1-p)}{\sqrt{1+a^2}}\right)}, \text{ and}$$

consequently $x_1^2 + y_1^2 = a^2 r^2 \left\{ \frac{1+a^2}{\cos\left(\frac{a(p_1-p)}{\sqrt{1+a^2}}\right)} - 1 \right\}$, and this last equation combined with $x_1^2 + y_1^2 = a^4 r^2 + a^2(z_1 - arp)^2$

$(z_1 - arp)^2$ will give $z_1 - arp = \pm (1+a^2)^{\frac{1}{2}} r \tan \frac{a(p_1-p)}{\sqrt{1+a^2}}$. From this last equation, and from the two

$x_1 \sin p + y_1 \cos p = a(z_1 - arp)$, $x_1 \cos p + y_1 \sin p = -a^2 r$ we may derive the values of x_1 , y_1 , and z_1 in function of p , and we shall obtain thus three relations, which are contained in the formulæ

$$\frac{x_1 + a^2 r \cos p}{a} = \frac{y_1 + a^2 r \sin p}{-a} = \frac{z_1 - arp}{1} = \pm (1+a^2)^{\frac{1}{2}} r \tan \frac{a(p_1-p)}{\sqrt{1+a^2}},$$

which alone may represent each of the evolutes of the helix. These formulæ show that the coordinates x_1 , y_1 , and z_1 of each evolute become infinite whenever the angle p obtains a value of the form $p = p_1 \pm (2n+1)\frac{\pi}{2}$

$\frac{\sqrt{1+a^2}}{a}$, n being any integer whatever. Moreover whilst the angle p converges towards one of these values, the

point (x_1, y_1, z_1) is always situated on the *surface développable* whose equation we have found, and approaches indefinitely that generating line of the same surface to which the equations $x_1 \sin p - y_1 \cos p = a(z_1 - arp)$, $x_1 \cos p + y_1 \sin p = -a^2 r$, when for p the above value has been substituted. Therefore each evolute will be composed of an infinite number of infinite branches, each of which will have for its asymptotes two of the generating lines of the surface.

If we call r_2 and p_2 the polar coordinates of the projection of one of these evolutes on the plane (x, y) , we shall have $x_1 = r_2 \cos p_2$, $y_1 = r_2 \sin p_2$, and consequently we shall have

$$r_2 \sin(p - p_2) = \pm a(1+a^2)^{\frac{1}{2}} r \tan \frac{a(p_1-p)}{\sqrt{1+a^2}}, \quad r_2 \cos(p - p_2) = -a^2 r.$$

These two equations combined with $z_1 - arp = \pm (1+a^2)^{\frac{1}{2}} r \tan \frac{a(p_1-p)}{\sqrt{1+a^2}}$ may be used with advantage to

Integral
Calculus.

discover the properties of the evolutes of the helix. If for more simplicity we assume $p_1 = 0$, these equations become Part III.

$$z_1 - arp = \mp (1 + a^2)^{\frac{1}{2}} r \tan \frac{ap}{\sqrt{1 + a^2}}, \quad r_2 \sin(p - p_2) = \mp a(1 + a^2)^{\frac{1}{2}} r \tan \frac{ap}{\sqrt{1 + a^2}},$$

$$r_2 \cos(p - p_2) = -a^2 r,$$

and will represent that evolute upon which is situated the centre of curvature corresponding to the point of the helix, which coincides with the origin of coordinates. To return from these last formulæ to those we mentioned just before, it is obviously sufficient to replace the quantities p , p_2 and z_1 by the differences $p - p_1$, $p_2 - p_1$, $z_1 - arp_1$. But the substitution of $p - p_1$ for p , and of the ordinate $z_1 - arp_1$ for z_1 , is precisely that which it is necessary to perform in order that the curve to which belong the three coordinates p_2 , r_2 , and z_1 should displace itself in space, in such a manner that each point should describe first, in turning round the axis of z , with a direct motion of rotation, if p_1 be positive, the angle $+p_1$, or with a retrograde motion of rotation, if p_1 be negative, the angle $-p_1$, and afterwards should move upon a line parallel to the axis of z of a quantity equal to arp , in the direction of the positive values of z , or of a quantity equal to $-arp$, in the direction of the negative values of z . Therefore this displacement is sufficient to transform the evolute we have last considered in any one of the other evolutes of the helix. Therefore these evolutes are curves which may be made to coincide with each other. If

we should take for p_1 , one of the values contained in the formula $p_1 = \pm (2n + 1) \frac{\pi}{2} \frac{\sqrt{1 + a^2}}{a}$, it will be the

various branches of the first evolute, which will be made to coincide by the displacement we have just indicated. Therefore all the branches of one of the evolutes are equal, and may be made to coincide with each other. These remarkable properties of the evolutes of the helix, depend upon the regular form of this curve, which may be made to coincide with itself by moving it, at the same time, round the axis of z and parallel to that axis.

(362.) When two curves of double curvature have a common point, and when they have, at this point, not only the same tangent, but also the same osculating circle, and consequently the same osculating plane, the same principal normal and the same curvature, then one of the curves is said to be an *osculating curve* of the other, or the contact which exists between the two curves is called an *osculation*. This understood, the following proposition results obviously from what precedes.

In order that a curve of double curvature should be an osculating curve of another curve of double curvature, at a point common to both corresponding to an abscissa equal x , it will be necessary and sufficient that the ordinates y and z relative to that abscissa, and their differential coefficients of the first and second order, that is to

say, the six quantities $y, y' = \frac{dy}{dx}, y'' = \frac{d^2y}{dx^2}, z, z' = \frac{dz}{dx}, z'' = \frac{d^2z}{dx^2}$, should preserve the same values in passing from one curve to the other. And reciprocally when one of the curves is an osculating curve of the other, these conditions must be satisfied.

An immediate consequence of this proposition is clearly that when one of the curves is an osculating curve of the other, their projections upon the coordinate planes, and generally upon any plane whatever, have the same relation of contact as the curves themselves.

From this proposition it also follows that, two curves of double curvature being represented by two equations between the coordinates x, y, z to determine whether one of the curves is an osculating curve of the other, it will be sufficient to take for the independent variable, either a given function of the variables x, y, z , or the arcs s , reckoned upon each curve from a fixed point, and to examine whether for the given point the same values of $x, y, z, dx, dy, dz, d^2x, d^2y, d^2z$, may be derived from the equations of the two curves.

If one of the curves be the intersection of the sphere and plane represented by the equations

$$(x - x_1)^2 + (y - y_1)^2 + (z - z_1)^2 = \rho^2, \quad (x - x_1) \cos l + (y - y_1) \cos m + (z - z_1) \cos n = 0,$$

the conditions to express that the point (x, y, z) is a point of osculation will suffice to determine the radius of the circle and the coordinates of the centre, that is to say, the four quantities x_1, y_1, z_1 , and ρ , with two of the three angles l, m, n , between which we have the relation $\cos^2 l + \cos^2 m + \cos^2 n = 1$. Let us suppose that x is taken for the independent variable, then the values of y, y', y'', z, z', z'' , derived from the equations of the other curve and its differential equations, must satisfy the equations of the circle and its differential equations, that is to say, the six following formulæ :

$$(x - x_1)^2 + (y - y_1)^2 + (z - z_1)^2 = \rho^2, \quad x - x_1 + (y - y_1) y' + (z - z_1) z' = 0,$$

$$1 + y'^2 + z'^2 + (y - y_1) y'' + (z - z_1) z'' = 0, \quad (x - x_1) \cos l + (y - y_1) \cos m + (z - z_1) \cos n = 0,$$

$$\cos l + y' \cos m + z' \cos n = 0, \quad y'' \cos m + z'' \cos n = 0.$$

When by means of these formulæ joined to the equation $\cos^2 l + \cos^2 m + \cos^2 n = 1$, the values of l, m, n, x_1, y_1, z_1 , and ρ are determined, we find identically the same values we have obtained before.

If x were not taken for the independent variable, then the equations of the circle and its differential equations of the first and second order might be represented by

$$(x - x_1)^2 + (y - y_1)^2 + (z - z_1)^2 = \rho^2, \quad (x - x_1) dx + (y - y_1) dy + (z - z_1) dz = 0,$$

$$(x - x_1) d^2x + (y - y_1) d^2y + (z - z_1) d^2z = -ds^2, \quad (x - x_1) \cos l + (y - y_1) \cos m + (z - z_1) \cos n = 0,$$

$$\cos l dx + \cos m dy + \cos n dz = 0, \quad \cos l d^2x + \cos m d^2y + \cos n d^2z = 0,$$

Integral Calculus. and ought to be verified by the values of $x, y, z, dx, dy, dz, d^2x, d^2y, d^2z$, determined by means of the equations of the other curves. Part III.

(363.) Let us now consider a curve surface represented by the equation $u = 0$, in which u designates, as usual, a function of the three coordinates x, y, z . If through a given point (x, y, z) on this surface, we conceive a normal plane, the intersection of this plane with the surface will be a certain curve, which we shall call a *normal section*. Let ρ be the radius of curvature of this curve relative to the point (x, y, z) , and x_1, y_1, z_1 the coordinates of the corresponding centre of curvature. We shall have $(x - x_1)^2 + (y - y_1)^2 + (z - z_1)^2 = \rho^2$, and since the centre

of curvature is situated on the normal, we shall have $\frac{x - x_1}{\left(\frac{du}{dx}\right)} = \frac{y - y_1}{\left(\frac{du}{dy}\right)} = \frac{z - z_1}{\left(\frac{du}{dz}\right)}$. Let us observe, now, that the

equation $(x - x_1)^2 + (y - y_1)^2 + (z - z_1)^2 = \rho^2$, when x, y , and z alone are supposed to be variables, is one of the equations of the osculating circle of the normal section under consideration, and, consequently, that the differential equation of the second order of that same equation,

$$(x - x_1) d^2x + (y - y_1) d^2y + (z - z_1) d^2z + dx^2 + dy^2 + dz^2 = 0,$$

ought to be satisfied by the values of $x, y, z, dx, dy, dz, d^2x, d^2y, d^2z$, derived from the equations of the normal section.

If we designate by s the arc of this curve, we have $ds^2 = dx^2 + dy^2 + dz^2$, and the above equation is then reduced to $(x - x_1) d^2x + (y - y_1) d^2y + (z - z_1) d^2z = -ds^2$. But if we differentiate twice the equation of the surface, we have

$$\begin{aligned} \frac{du}{dx} d^2x + \frac{du}{dy} d^2y + \frac{du}{dz} d^2z + \frac{d^2u}{dx^2} dx^2 + \frac{d^2u}{dy^2} dy^2 + \frac{d^2u}{dz^2} dz^2 + \frac{2d^2u}{dydz} dydz \\ + \frac{2d^2u}{dzdx} dzdx + \frac{2d^2u}{dxdy} dxdy = 0. \end{aligned}$$

Let, for brevity sake,

$$q = \frac{d^2u}{dx^2} \frac{dx^2}{ds^2} + \frac{d^2u}{dy^2} \frac{dy^2}{ds^2} + \frac{d^2u}{dz^2} \frac{dz^2}{ds^2} + \frac{2d^2u}{dydz} \frac{dydz}{ds^2} + \frac{2d^2u}{dzdx} \frac{dzdx}{ds^2} + \frac{2d^2u}{dxdy} \frac{dxdy}{ds^2},$$

then the equation above will be reduced to

$$\frac{du}{dx} d^2x + \frac{du}{dy} d^2y + \frac{du}{dz} d^2z = -ds^2.$$

If we assume

$$r = \sqrt{\left(\frac{du}{dx}\right)^2 + \left(\frac{du}{dy}\right)^2 + \left(\frac{du}{dz}\right)^2},$$

we shall have

$$\begin{aligned} \frac{x - x_1}{\left(\frac{du}{dx}\right)} = \frac{y - y_1}{\left(\frac{du}{dy}\right)} = \frac{z - z_1}{\left(\frac{du}{dz}\right)} = \pm \frac{\left\{ (x - x_1)^2 + (y - y_1)^2 + (z - z_1)^2 \right\}^{\frac{1}{2}}}{\sqrt{\left(\frac{du}{dx}\right)^2 + \left(\frac{du}{dy}\right)^2 + \left(\frac{du}{dz}\right)^2}} = \pm \frac{\rho}{r} \\ = \frac{(x - x_1) d^2x + (y - y_1) d^2y + (z - z_1) d^2z}{\frac{du}{dx} d^2x + \frac{du}{dy} d^2y + \frac{du}{dz} d^2z} = \frac{1}{q}, \end{aligned}$$

and consequently, $\frac{1}{\rho} = \pm \frac{q}{r}$. It is essential to observe that the quantity r represents a known function of the

quantities x, y, z . As to the quantity q it may be expressed in function of the coordinates x, y, z , and the angles which the tangent to the normal section through the point (x, y, z) makes with the coordinate axis. Let α, β, γ be these angles, we shall have

$$\cos \alpha = \frac{dx}{ds}, \cos \beta = \frac{dy}{ds}, \cos \gamma = \frac{dz}{ds}, \text{ or else } \cos \alpha = -\frac{dx}{ds}, \cos \beta = -\frac{dy}{ds}, \cos \gamma = -\frac{dz}{ds},$$

and in both cases we shall have

$$q = \frac{d^2u}{dx^2} \cos^2 \alpha + \frac{d^2u}{dy^2} \cos^2 \beta + \frac{d^2u}{dz^2} \cos^2 \gamma + 2 \frac{d^2u}{dydz} \cos \beta \cos \gamma + 2 \frac{d^2u}{dzdx} \cos \gamma \cos \alpha + 2 \frac{d^2u}{dxdy} \cos \beta \cos \alpha.$$

Now, it is clear that the second member of this last equation, is a known function of the variables $x, y, z, \alpha, \beta, \gamma$; and, therefore, if with the point (x, y, z) the tangent drawn through this point to a normal section is also given, it will be easy by means of the preceding formulæ to find the radius and centre of curvature of that normal section.

When we pass from a normal section to another without displacing the point (x, y, z) the angles α, β, γ take other values, and the same thing takes place, at least generally speaking, with respect to the quantity q and the variables x, y, z , and ρ which depend upon it. If in this passage it should happen that the quantity ρ change

its sign, then the radius of curvature of one of the sections would be determined by the equation $\frac{1}{\rho} = -\frac{q}{r}$.

Integral
Calculus.

and that of the other section by the equation $\frac{1}{\rho} = \frac{-q}{r}$, since the quantities ρ and r are essentially positive. On the other side, the quantities $\frac{du}{dx}, \frac{du}{dy}, \frac{du}{dz}$, being independent of the angles α, β, γ , it may be affirmed that if in

the passage of one section to another, the quantity q changes its sign, the differences $x - x_1, y - y_1, z - z_1$, will also change theirs. Therefore the centres of curvature of the two sections will be situated with respect to the point (x, y, z) , on different sides, and both on the normal drawn through this point to the given surface; so that the radii of curvature will be in opposite directions.

The radii of curvature of the various normal sections which pass through the same point, present properties which deserve to be remarked. To discover these relations, it is first necessary to discover the law according to which the radius of curvature ρ varies with the angles α, β, γ . This law may be made very obvious by means of a geometrical construction, which consists in taking on the tangent to each normal section, on both sides of the point (x, y, z) two lengths equal to the radius of curvature corresponding, or to a positive power of this radius. The curve which will pass through the extremities of these lengths will clearly be a plane curve, contained in the tangent plane; and in the same manner as the radius vector drawn through the point (x, y, z) to this curve will vary, will the radius of curvature of the normal section tangent to that radius vector increase or decrease, so that it is clear that the nature of this curve will show the law according to which the radius of curvature varies. In the particular case where it is supposed that the length taken upon each tangent is equal to the square root of the radius of curvature corresponding, the curve we have just mentioned is reduced to a curve of the second degree.

For if we designate by x_1, y_1, z_1 , the coordinates of the extremity of a length equal to $\rho^{\frac{1}{2}}$ taken upon the tangent which forms with the axis the angles α, β, γ , we shall find $x_1 - x = \rho^{\frac{1}{2}} \cos \alpha, y_1 - y = \rho^{\frac{1}{2}} \cos \beta, z_1 - z = \rho^{\frac{1}{2}} \cos \gamma$; and if we place the origin of coordinates at the point (x, y, z) , we shall find $x_1 = \rho^{\frac{1}{2}} \cos \alpha, y_1 = \rho^{\frac{1}{2}} \cos \beta, z_1 = \rho^{\frac{1}{2}} \cos \gamma$. We have besides $q\rho = \pm r$, or substituting for q its value, we have

$$\frac{d^2 u}{dx^2} \cos^2 \alpha + \frac{d^2 u}{dy^2} \cos^2 \beta + \frac{d^2 u}{dz^2} \cos^2 \gamma + \frac{2 d^2 u}{dy dz} \cos \beta \cos \gamma + \frac{2 d^2 u}{dz dx} \cos \gamma \cos \alpha + \frac{2 d^2 u}{dy dx} \cos \beta \cos \alpha = \pm r.$$

Therefore if for $\cos \alpha, \cos \beta, \cos \gamma$, the values $\frac{x_1}{\rho^{\frac{1}{2}}}, \frac{y_1}{\rho^{\frac{1}{2}}}, \frac{z_1}{\rho^{\frac{1}{2}}}$, are substituted, we shall have

$$\frac{d^2 u}{dx^2} x_1^2 + \frac{d^2 u}{dy^2} y_1^2 + \frac{d^2 u}{dz^2} z_1^2 + \frac{2 d^2 u}{dy dz} y_1 z_1 + \frac{2 d^2 u}{dz dx} x_1 z_1 + \frac{2 d^2 u}{dy dx} y_1 x_1 = \pm r.$$

This last equation, when x_1, y_1 , and z_1 , are considered as the only variables, represents a surface of the second degree which contains the plane curve above mentioned. It may be remarked, that this surface has for its centre the new origin of coordinates, that is the point (x, y, z) ; and as the plane of the curve passes also through the same point, we may conclude that the curve in question is a line of the second degree which has for its centre the point (x, y, z) . To obtain the two equations of this curve, it is sufficient to join to the above equation of the surface of the second degree, the equation of the tangent plane, at the point (x, y, z) , when the origin is placed

at that point, that is to say, the equation $x_1 \frac{du}{dx} + y_1 \frac{du}{dy} + z_1 \frac{du}{dz} = 0$. But if λ, μ, ν represent the angles

which the normal makes with the axis, we have $\frac{\cos \lambda}{\left(\frac{du}{dx}\right)} = \frac{\cos \mu}{\left(\frac{du}{dy}\right)} = \frac{\cos \nu}{\left(\frac{du}{dz}\right)}$, and, consequently, the equation of

the plane containing the curve of the second degree takes the form $x_1 \cos \lambda + y_1 \cos \mu + z_1 \cos \nu = 0$.

From all that precedes it follows, that the curve drawn in the tangent plane according to the construction indicated, will be reduced, in general, to an ellipse, or to the system of two conjugated hyperbolas; but that in certain particular cases it may be transformed into a circle, or in a single point, or in a system of two parallel straight lines, equally distant from the point (x, y, z) , or in a system of two straight lines drawn through that point. The same conclusion results also from the form which takes the equation

$$\frac{d^2 u}{dx^2} x_1^2 + \frac{d^2 u}{dy^2} y_1^2 + \frac{d^2 u}{dz^2} z_1^2 + 2 \frac{d^2 u}{dy dz} y_1 z_1 + 2 \frac{d^2 u}{dz dx} x_1 z_1 + 2 \frac{d^2 u}{dy dx} y_1 x_1 = \pm r,$$

when the plane of (x, y) is parallel to the tangent plane drawn through the point (x, y, z) . Then the equation of the plane of the curve is reduced to $z_1 = 0$, and in combining this with the above equation, it reduces it to

$$\frac{d^2 u}{dx^2} x_1^2 + \frac{d^2 u}{dy^2} y_1^2 + 2 \frac{d^2 u}{dy dx} y_1 x_1 = \pm r. \text{ Now it is well known that this equation will represent an ellipse}$$

when the difference $\frac{d^2 u}{dx^2} \cdot \frac{d^2 u}{dy^2} - \left(\frac{d^2 u}{dy dx}\right)^2$ is positive, two conjugate hyperbolas when this difference becomes negative, and two parallel lines if this difference is equal to nothing. The ellipse becomes a circle when

Integral Calculus. $\frac{d^2 u}{d x^2} = \frac{d^2 u}{d y^2}$, and $\frac{d^2 u}{d x d y} = 0$, and a point when $r = 0$, in this last case the two conjugate hyperbolas are transformed into two straight lines. Since the plane of (x, y) may be chosen arbitrarily, the preceding reasoning

may obviously be applied to any point of the surface. In order that the equation $x_1 \frac{d u}{d x} + y_1 \frac{d u}{d y} + z_1 \frac{d u}{d z} = 0$

should become, as we have just supposed, $z_1 = 0$, it is necessary that of the three quantities $\frac{d u}{d x}, \frac{d u}{d y}, \frac{d u}{d z}$, the two

first should vanish, or the third become infinite. In the first case $r = \pm \frac{d u}{d z}$, and the equation of the curve

becomes $\frac{d^2 u}{d x^2} x_1^2 + 2 \frac{d^2 u}{d x d y} x_1 y_1 + \frac{d^2 u}{d y^2} y_1^2 = \pm \frac{d u}{d z}$. Since the radius of curvature ρ of a normal section is the

square of the radius vector $\sqrt{(x_1^2 + y_1^2)}$ drawn through the point (x, y, z) to a point of the line of the second degree drawn in the tangent plane, it is obvious that each of the normal planes which pass through the axis of this line produces a normal section, the radius of curvature of which is a *maximum* or a *minimum*. We shall call principal sections, and principal radii of curvature, the two normal sections in question, and their radii of curvature. This understood, it is clear that the planes of the principal sections are always at right angles to each other, and that the principal radii of curvature are in the same or opposite directions according to the conditions above stated; the first case will take place when the curve drawn in the tangent plane is an ellipse, the second when this curve is a system of two conjugate hyperbolas. In the first case these radii of curvature will represent the one a maximum, the other a minimum of the variable ρ , and in the second case two values minima of the same variable. In other words, if the curve drawn in the tangent plane be an ellipse, the two principal sections will be the two normal sections of greatest and least curvature; but if this curve be a system of two conjugate hyperbolas, both principal sections will be normal sections of greatest curvature, only their curvatures will be in opposite directions. In the same hypothesis the normal sections, the planes of which would contain the asymptotes common to both hyperbolas, would have curvatures equal to nothing corresponding to values of ρ equal to infinity. Hence the planes of the two normal sections, of which the curvatures are equal to nothing, will form equal angles with the planes of the principal sections.

When the ellipse becomes a circle, all the normal sections have equal curvatures, and then the name of principal sections may be given to any two normal sections the planes of which are at right angles to each other.

When the difference $\frac{d^2 u}{d x^2} \cdot \frac{d^2 u}{d y^2} - \left(\frac{d^2 u}{d x d y} \right)^2 = 0$, the line in the tangent plane is reduced to two parallel

straight lines, which may be considered as representing an ellipse the greater axis of which has become infinite. In this case the principal sections correspond to a minimum value and to an infinite value of ρ , so that one of the sections has a curvature equal to nothing.

If the quantity r should vanish, all the normal sections would have radii of curvature equal to nothing or infinity.

It may easily be proved that if by the centre of an ellipse or of two conjugate hyperbolas, two radii are drawn to the curve at right angles to each other, the lengths of which are represented by r_1 and r_2 , the quantity $\frac{1}{r_1^2} + \frac{1}{r_2^2}$ is a constant quantity equal to $\frac{1}{a^2} + \frac{1}{b^2}$, a and b being the two axes of the ellipse, or the real axis of the two

conjugate hyperbolas, provided, however, that, in the case of the conjugate hyperbolas, if we have agreed to take with the sign $+$ one of the quotients relative to one of the hyperbolas, the other, when it will refer to the second hyperbola, should be taken with the sign $-$.

From this proposition it clearly follows that if we draw through a point (x, y, z) of a surface two planes at right angles to each other, and normal to the surface, and if we divide successively unity by each of the radii of curvature of the two lines of intersection, the sum of the quotients will be a constant quantity, provided that in this sum we always take with the sign $+$ the radii drawn in a certain direction, and with the sign $-$ the radii in the opposite direction. Consequently this sum will be equal, without paying attention to the sine, to the sum or to the difference of the quotients relative to the principal radii of curvature.

(364.) We may also easily find the relation which exists between the radius of curvature of any normal section, and the angles formed by the plane of that section with the principal sections. To obtain it, let us first observe that, in the case where the tangent plane to the proposed surface is parallel to the plane of (x, y) , we have for

the tangent to each normal section $\cos \gamma = 0$, $\cos^2 \alpha + \cos^2 \beta = 1$. Hence we shall have in that case $q = \frac{d u}{d x^2}$

$\cos^2 \alpha + 2 \frac{d^2 u}{d x d y} \cos \alpha \cos \beta + \frac{d^2 u}{d y^2} \cos^2 \beta$. This value of q becomes still simpler, when we suppose the planes

of x, z , and y, z parallel to the planes of the principal sections. Then the equation of the curve drawn in the tangent plane, belonging to a curve of the second degree referred to its axis, cannot contain the product of the

Integral
Calculus.

Part III.

coordinates x_1 and y_1 , and must be reduced to $\frac{d^2 u}{d x^2} x_1^2 + \frac{d^2 u}{d y^2} y_1^2 = \pm r$. Therefore we have $\frac{d^2 u}{d y d x} = 0$, and,

consequently, the value of q becomes $q = \frac{d^2 u}{d x^2} \cos^2 \alpha + \frac{d^2 u}{d y^2} \cos^2 \beta$. But we have also $\cos^2 \beta = 1 - \cos^2 \alpha =$

$\sin^2 \alpha$, hence the value of q may be written $q = \frac{d^2 u}{d x^2} \cos^2 \alpha + \frac{d^2 u}{d y^2} \sin^2 \alpha$. This understood, the formula $\frac{1}{\rho} = \pm$

$\frac{q}{r}$ will give $\frac{1}{\rho} = \pm \frac{1}{r} \left\{ \frac{d^2 u}{d x^2} \cos^2 \alpha + \frac{d^2 u}{d y^2} \sin^2 \alpha \right\}$. Let now ρ_0 and ρ_1 be the principal radii of curvature. To

obtain their values it will be sufficient to assume successively in the preceding formula $\alpha = 0$ and $\alpha = \frac{\pi}{2}$. We

shall find thus $\frac{1}{\rho_0} = \pm \frac{1}{r} \frac{d^2 u}{d x^2}$, $\frac{1}{\rho_1} = \pm \frac{1}{r} \frac{d^2 u}{d y^2}$, and, consequently, $\frac{1}{\rho} = \pm \frac{1}{\rho_0} \cos^2 \alpha \pm \frac{1}{\rho_1} \sin^2 \alpha$. It is essential

to observe that $\frac{d^2 u}{d x^2}$, $\frac{d^2 u}{d y^2}$ are quantities of the same sign in the case where the curve drawn in the tangent plane is an ellipse, and of contrary sign when it is two conjugate hyperbolas. Hence in the first case, we shall have

$\frac{1}{\rho} = \frac{1}{\rho_0} \cos^2 \alpha + \frac{1}{\rho_1} \sin^2 \alpha$, and in the second case $\pm \frac{1}{\rho} = \frac{1}{\rho_0} \cos^2 \alpha - \frac{1}{\rho_1} \sin^2 \alpha$, the sign $+$ in the left side being

taken when the radius of curvature ρ is in the same direction as ρ_0 , and the sign $-$ when it is in the same direction

as the radius ρ_1 . If the differential coefficients $\frac{d^2 u}{d x^2}$, $\frac{d^2 u}{d y^2}$ are equal, the curve described in the tangent plane

becomes a circle. At the same time we shall have $\rho_1 = \rho_0$ and $\rho = \rho_0$.

If one of the two quantities $\frac{d^2 u}{d x^2}$, $\frac{d^2 u}{d y^2}$ is equal to nothing, the line drawn in the tangent plane becomes the

system of two parallel lines. One of the radii ρ_0 , ρ_1 then becomes infinite; let $\frac{d^2 u}{d y^2} = 0$, we shall have $\rho_1 = \infty$,

and the formula will give $\frac{1}{\rho} = \frac{1}{\rho_0} \cos^2 \alpha$. In this case ρ_0 is the radius of curvature of the normal section which has for its tangent a straight line perpendicular to the two parallel straight lines drawn through the point (x, y, z) .

If we add to the value of $\frac{1}{\rho}$, what becomes that value when for α , $\alpha + \frac{\pi}{2}$ is substituted, we find $\pm \frac{1}{\rho_0} \pm \frac{1}{\rho_1}$, a result agreeing with the theorem stated at the end of the preceding paragraph.

(365.) Let us suppose now, that it is required to find in space for any point (x, y, z) of the given surface the directions of the tangents to the principal sections, and the principal radii of curvature. It will evidently be sufficient to find the maximum and minimum, or the two minima of the radius of curvature $\rho = x_1^2 + y_1^2 + z_1^2$, the coordinates x_1 , y_1 , and z_1 being connected by the two equations

$$\frac{d^2 u}{d x^2} x_1^2 + \frac{d^2 u}{d y^2} y_1^2 + \frac{d^2 u}{d z^2} z_1^2 + \frac{2 d^2 u}{d y d z} y_1 z_1 + \frac{2 d^2 u}{d z d x} z_1 x_1 + \frac{2 d^2 u}{d x d y} x_1 y_1 = \pm r, \quad x_1 \frac{d u}{d x} + y_1 \frac{d u}{d y} + z_1 \frac{d u}{d z} = 0.$$

Hence the values of x_1 , y_1 , and z_1 , corresponding to the principal radii of curvature, must satisfy the equation $x_1 d x_1 + y_1 d y_1 + z_1 d z_1 = 0$, after having eliminated $d x_1$, $d y_1$, $d z_1$, by means of the two equations

$$\left(\frac{d^2 u}{d x^2} x_1 + \frac{d^2 u}{d x d y} y_1 + \frac{d^2 u}{d x d z} z_1 \right) d x_1 + \left(\frac{d^2 u}{d x d y} x_1 + \frac{d^2 u}{d y^2} y_1 + \frac{d^2 u}{d y d z} z_1 \right) d y_1 + \left(\frac{d^2 u}{d x d z} x_1 + \frac{d^2 u}{d y d z} y_1 + \frac{d^2 u}{d z^2} z_1 \right) d z_1 = 0.$$

$$\frac{d u}{d x} d x_1 + \frac{d u}{d y} d y_1 + \frac{d u}{d z} d z_1 = 0.$$

If then we add the three last equations after having multiplied the first and last by two indeterminate coefficients $-s$, $-t$, it is clear that we may determine the values of s and t so as to render equal to nothing, in the resulting equation, the coefficients of $d x_1$, $d y_1$, $d z_1$, since it is obvious that these three quantities may be eliminated from the three equations. Thus the values of s and t may be determined so as to satisfy the three equations,

$$\frac{d^2 u}{d x^2} x_1 + \frac{d^2 u}{d x d y} y_1 + \frac{d^2 u}{d x d z} z_1 = s x_1 + t \frac{d u}{d x}, \quad \frac{d^2 u}{d x d y} x_1 + \frac{d^2 u}{d y^2} y_1 + \frac{d^2 u}{d y d z} z_1 = s y_1 + t \frac{d u}{d y},$$

$$\frac{d^2 u}{d x d z} x_1 + \frac{d^2 u}{d y d z} y_1 + \frac{d^2 u}{d z^2} z_1 = s z_1 + t \frac{d u}{d z}.$$

If we add these equations after having multiplied them respectively by x_1 , y_1 , z_1 , we shall have, $\pm r = s \rho$, or

Integral Calculus. $s = \pm \frac{r}{\rho} = q$, since we have already between the various quantities which enter into these equations, the relations Part III.

$$\frac{d^2 u}{dx^2} x_1^2 + \frac{d^2 u}{dy^2} y_1^2 + \frac{d^2 u}{dz^2} z_1^2 + \frac{2 d^2 u}{dz dy} z_1 y_1 + \frac{2 d^2 u}{dz dx} z_1 x_1 + \frac{2 d^2 u}{dy dx} y_1 x_1 = \pm r,$$

$$x_1 \frac{du}{dx} + y_1 \frac{du}{dy} + z_1 \frac{du}{dz} = 0, \text{ and } x_1^2 + y_1^2 + z_1^2 = \rho.$$

Now, since the quantity s is the same as the quantity q , the three above equations may be put under the following form,

$$\left(\frac{d^2 u}{dx^2} - q \right) x_1 + \frac{d^2 u}{dx dy} y_1 + \frac{d^2 u}{dx dz} z_1 = t \frac{du}{dx}, \quad \frac{d^2 u}{dx dy} x_1 + \left(\frac{d^2 u}{dy^2} - q \right) y_1 + \frac{d^2 u}{dy dz} z_1 = t \frac{du}{dy},$$

$$\frac{d^2 u}{dx dz} x_1 + \frac{d^2 u}{dy dz} y_1 + \left(\frac{d^2 u}{dz^2} - q \right) z_1 = t \frac{du}{dz}.$$

From which we shall derive the values of x, y, z . We shall find

$$x_1 = \kappa \left\{ \frac{du}{dx} \left[\left(\frac{d^2 u}{dy^2} - q \right) \left(\frac{d^2 u}{dz^2} - q \right) - \left(\frac{d^2 u}{dy dz} \right)^2 \right] + \frac{du}{dy} \left[\frac{d^2 u}{dz dx} \cdot \frac{d^2 u}{dy dz} - \left(\frac{d^2 u}{dz^2} - q \right) \frac{d^2 u}{dx dy} \right] \right.$$

$$\left. + \frac{du}{dz} \left[\frac{d^2 u}{dy dz} \cdot \frac{d^2 u}{dx dy} - \left(\frac{d^2 u}{dy^2} - q \right) \frac{d^2 u}{dz dx} \right] \right\},$$

$$y_1 = \kappa \left\{ \frac{du}{dx} \left[\frac{d^2 u}{dz dx} \cdot \frac{d^2 u}{dy dz} - \left(\frac{d^2 u}{dz^2} - q \right) \frac{d^2 u}{dx dy} \right] + \frac{du}{dy} \left[\left(\frac{d^2 u}{dz^2} - q \right) \left(\frac{d^2 u}{dx^2} - q \right) - \left(\frac{d^2 u}{dz dx} \right)^2 \right] \right.$$

$$\left. + \frac{du}{dz} \left[\frac{d^2 u}{dx dy} \frac{d^2 u}{dz dx} - \left(\frac{d^2 u}{dx^2} - q \right) \frac{d^2 u}{dy dz} \right] \right\},$$

$$z_1 = \kappa \left\{ \frac{du}{dx} \left[\frac{d^2 u}{dy dz} \frac{d^2 u}{dx dy} - \left(\frac{d^2 u}{dy^2} - q \right) \frac{d^2 u}{dz dx} \right] + \frac{du}{dy} \left[\frac{d^2 u}{dx dy} \frac{d^2 u}{dz dx} - \left(\frac{d^2 u}{dx^2} - q \right) \frac{d^2 u}{dy dz} \right] \right.$$

$$\left. + \frac{du}{dz} \left[\left(\frac{d^2 u}{dx^2} - q \right) \left(\frac{d^2 u}{dy^2} - q \right) - \left(\frac{d^2 u}{dx dy} \right)^2 \right] \right\}.$$

In these formulæ κ designates a quantity the value of which may be derived from the relation $x_1^2 + y_1^2 + z_1^2 = \rho$.

We find thus $\kappa = \frac{\pm \rho^{\frac{1}{2}}}{u}$, u^2 being the sum of the squares of the coefficients of κ in the values of x_1, y_1 , and z_1 .

Moreover, if we substitute these same values in the formulæ $x_1 \frac{du}{dx} + y_1 \frac{du}{dy} + z_1 \frac{du}{dz} = 0$, we find

$$0 = \left(\frac{du}{dx} \right)^2 \left[\left(\frac{d^2 u}{dy^2} - q \right) \left(\frac{d^2 u}{dz^2} - q \right) - \left(\frac{d^2 u}{dy dz} \right)^2 \right] + \left(\frac{du}{dy} \right)^2 \left[\left(\frac{d^2 u}{dz^2} - q \right) \left(\frac{d^2 u}{dx^2} - q \right) - \left(\frac{d^2 u}{dz dx} \right)^2 \right]$$

$$+ \left(\frac{du}{dz} \right)^2 \left[\left(\frac{d^2 u}{dx^2} - q \right) \left(\frac{d^2 u}{dy^2} - q \right) - \left(\frac{d^2 u}{dx dy} \right)^2 \right] + 2 \frac{du}{dy} \frac{du}{dz} \left[\frac{d^2 u}{dx dy} \frac{d^2 u}{dz dx} - \left(\frac{d^2 u}{dx^2} - q \right) \frac{d^2 u}{dy dz} \right]$$

$$+ 2 \frac{du}{dz} \frac{du}{dx} \left[\frac{d^2 u}{dy dz} \frac{d^2 u}{dx dy} - \left(\frac{d^2 u}{dy^2} - q \right) \frac{d^2 u}{dz dx} \right] + 2 \frac{du}{dy} \frac{du}{dx} \left[\frac{d^2 u}{dz dx} \frac{d^2 u}{dy dz} - \left(\frac{d^2 u}{dz^2} - q \right) \frac{d^2 u}{dx dy} \right].$$

This equation is of the second degree with respect to q , and the two values it gives for that quantity are those corresponding to the two principal radii of curvature. Knowing these values of q , the equation $\rho = \pm \frac{r}{q}$ will give the values of the two principal radii of curvature, and the above values of x_1, y_1, z_1 , together with the equation $\kappa = \pm \frac{\rho^{\frac{1}{2}}}{u}$, will give the coordinates of four points situated on the tangents to the principal sections.

To determine the directions of these tangents, we have the equations

$$x_1 = \rho^{\frac{1}{2}} \cos \alpha, \quad y_1 = \rho^{\frac{1}{2}} \cos \beta, \quad z_1 = \rho^{\frac{1}{2}} \cos \gamma.$$

When the variables x, y, z are separated in the equation $u = 0$, that is to say, when the function u is divided into three parts, each of which contains only one of the variables x, y, z , we have for all the points of the given surface $\frac{d^2 u}{dy dz} = 0, \frac{d^2 u}{dz dx} = 0, \frac{d^2 u}{dx dy} = 0$. Then the equations which, in the general case, give the values of x_1, y_1 , and z_1 , become

$$\left(\frac{d^2 u}{dx^2} - q \right) x_1 = t \frac{du}{dx}, \quad \left(\frac{d^2 u}{dy^2} - q \right) y_1 = t \frac{du}{dy}, \quad \left(\frac{d^2 u}{dz^2} - q \right) z_1 = t \frac{du}{dz},$$

Integral
Calculus.and by substituting the values of x_1 , y_1 , and z_1 , derived from these formulæ, in the equation

$$x_1 \frac{du}{dx} + y_1 \frac{du}{dy} + z_1 \frac{du}{dz} = 0,$$

we find

$$\frac{\left(\frac{du}{dx}\right)^2}{\frac{d^2u}{dx^2} - q} + \frac{\left(\frac{du}{dy}\right)^2}{\frac{d^2u}{dy^2} - q} + \frac{\left(\frac{du}{dz}\right)^2}{\frac{d^2u}{dz^2} - q} = 0.$$

These same formulæ combined with the equation $\rho = x_1^2 + y_1^2 + z_1^2$, will give

$$t = \pm \rho^{\frac{1}{2}} \left\{ \left(\frac{\frac{du}{dx}}{\frac{d^2u}{dx^2} - q} \right)^2 + \left(\frac{\frac{du}{dy}}{\frac{d^2u}{dy^2} - q} \right)^2 + \left(\frac{\frac{du}{dz}}{\frac{d^2u}{dz^2} - q} \right)^2 \right\}^{-\frac{1}{2}},$$

and then, by means of the formulæ $x_1 = \rho^{\frac{1}{2}} \cos \alpha$, $y_1 = \rho^{\frac{1}{2}} \cos \beta$, $z_1 = \rho^{\frac{1}{2}} \cos \gamma$, we get

$$\frac{\left(\frac{d^2u}{dx^2} - q\right) \cos \alpha}{\frac{du}{dx}} = \frac{\left(\frac{d^2u}{dy^2} - q\right) \cos \beta}{\frac{du}{dy}} = \frac{\left(\frac{d^2u}{dz^2} - q\right) \cos \gamma}{\frac{du}{dz}} = t.$$

These formulæ joined to the relation $\frac{1}{\rho} = \pm \frac{q}{r}$ will be sufficient, in the present hypothesis, to determine the directions of the tangents to the principal sections, and the principal radii of curvature.

We shall apply these formulæ to a few examples.

1. Let the proposed surface be the ellipsoid represented by the equation $\frac{x^2}{a^2} + \frac{y^2}{b^2} + \frac{z^2}{c^2} = 1$. We may assume $u = \frac{1}{2} \left(\frac{x^2}{a^2} + \frac{y^2}{b^2} + \frac{z^2}{c^2} - 1 \right)$, and then we shall find

$$\frac{du}{dx} = \frac{x}{a^2}, \quad \frac{du}{dy} = \frac{y}{b^2}, \quad \frac{du}{dz} = \frac{z}{c^2}, \quad \frac{d^2u}{dx^2} = \frac{1}{a^2}, \quad \frac{d^2u}{dy^2} = \frac{1}{b^2}, \quad \frac{d^2u}{dz^2} = \frac{1}{c^2}.$$

Then the equation which determines the value of q will become

$$\frac{x^2}{a^2(1 - qa^2)} + \frac{y^2}{b^2(1 - qb^2)} + \frac{z^2}{c^2(1 - qc^2)} = 0.$$

We shall have also

$$\frac{1}{\rho} = \pm q \left(\frac{x^2}{a^4} + \frac{y^2}{b^4} + \frac{z^2}{c^4} \right)^{-\frac{1}{2}},$$

and

$$\frac{(1 - qa^2) \cos \alpha}{x} = \frac{(1 - qb^2) \cos \beta}{y} = \frac{(1 - qc^2) \cos \gamma}{z} = \pm \left\{ \left(\frac{x}{1 - qa^2} \right)^2 + \left(\frac{y}{1 - qb^2} \right)^2 + \left(\frac{z}{1 - qc^2} \right)^2 \right\}^{-\frac{1}{2}}.$$

These formulæ will be sufficient to determine in each point of the ellipsoid the directions of the tangents to the principal sections, and the two principal radii of curvature. Moreover, if we subtract from the equation of the ellipsoid the equation which is used to determine the values of q , we get

$$\frac{x^2}{a^2 - \frac{1}{q}} + \frac{y^2}{b^2 - \frac{1}{q}} + \frac{z^2}{c^2 - \frac{1}{q}} = 1. \text{ Which equation}$$

shows, that if, after having calculated one of the maximum or minimum values of the variable q , a new ellipsoid is constructed, the semi-axis of which, designated by a_1 , b_1 , c_1 are determined by the equations

$$a_1^2 = a^2 - \frac{1}{q}, \quad b_1^2 = b^2 - \frac{1}{q}, \quad c_1^2 = c^2 - \frac{1}{q},$$

this new ellipsoid will also pass through the point (x, y, z) . It may be remarked, that the sections made by the coordinate planes in the proposed ellipsoid and in the new ellipsoid will have the same foci, since

$$a^2 - b^2 = a_1^2 - b_1^2, \quad a^2 - c^2 = a_1^2 - c_1^2, \quad b^2 - c^2 = b_1^2 - c_1^2.$$

2. Let us conceive that after having drawn, in the plane of x, y , a curve represented by the equation $y = f(x)$, we make this curve turn round the axis of x . It will generate a surface of revolution, in which the distance of the point (x, y, z) from the axis of x , which is $\sqrt{y^2 + z^2}$, will be equal, without taking into consideration the sign, to the ordinate of the generating curve. Therefore we shall have for every point of the surface

$$\sqrt{y^2 + z^2} = \pm f(x), \text{ or } y^2 + z^2 = (f(x))^2.$$

Integral Calculus.

We may assume $u = \frac{1}{2} \{ y^2 + z^2 - (f(x))^2 \}$, and we shall find then

$$\frac{du}{dz} = -f(x)f'(x), \frac{du}{dy} = y, \frac{du}{dz} = z, \frac{d^2u}{dx^2} = -\{ (f'(x))^2 + f(x)f''(x) \}, \frac{d^2u}{dy^2} = 1, \frac{d^2u}{dz^2} = 1.$$

Then the equation to determine the value of q , in the case where the variables x, y, z are separated, will become

$$\frac{\{f(x)f'(x)\}^2}{q + (f'(x))^2 + f(x)f''(x)} + \frac{y^2 + z^2}{q - 1} = 0. \text{ If then we substitute for } y^2 + z^2 \text{ its value } (f(x))^2, \text{ we shall}$$

$$\text{find } q = -\frac{f(x)f''(x)}{1 + (f'(x))^2}. \text{ We shall have besides, } r = \sqrt{\{y^2 + z^2 + (f(x)f'(x))^2\}} = \pm f(x) \sqrt{1 +}$$

$$(f'(x))^2\}. \text{ Consequently, } \rho = \pm \frac{\{1 + (f'(x))^2\}^{\frac{3}{2}}}{f''(x)}. \text{ This value of } \rho \text{ is the radius of curvature of the}$$

generating curve, which in fact coincides with one of the principal sections of the surface of revolution. As to the radius of curvature of the other principal section, it will be sufficient to determine it to take the three equations in q and t , which in the present case will be reduced to

$$\{q + (f'(x))^2 + f(x)f''(x)\}x_1 = t f(x)f'(x), (1 - q)y_1 = t y, (1 - q)z_1 = t z.$$

These three equations are verified by taking $q = 1, t = 0, x_1 = 0$, therefore the formula $\frac{1}{\rho} = \pm \frac{q}{r}$ will give $\rho =$

$\pm r = \pm f(x) \{1 + (f'(x))^2\}^{\frac{1}{2}}$, a value which is precisely that of the normal to the generating curve. Besides, since $x_1 = 0$, we shall have $\cos \alpha = 0$; and therefore it is obvious that the principal section corresponding to this radius of curvature will have for its tangent a straight line contained in a plane perpendicular to the axis of x .

(366.) The general formulæ we have obtained become simpler when the equation of the surface is resolved with respect to z , and reduced to the form $z = f(x, y)$.

Let us assume then

$$\frac{df(x, y)}{dx} = p, \frac{df(x, y)}{dy} = q, \frac{d^2f(x, y)}{dx^2} = r, \frac{d^2f(x, y)}{dx dy} = s, \frac{d^2f(x, y)}{dy^2} = t.$$

We shall have $u = f(x, y) - z$, and, consequently,

$$\frac{du}{dx} = p, \frac{du}{dy} = q, \frac{du}{dz} = -1, \frac{d^2u}{dx^2} = r, \frac{d^2u}{dy^2} = t, \frac{d^2u}{dz^2} = 0, \frac{d^2u}{dy dz} = 0, \frac{d^2u}{dz dx} = 0, \frac{d^2u}{dx dy} = s.$$

These values being substituted in the preceding formulæ will give $r_1 = \sqrt{1 + p^2 + q^2}$, $q = r \cos^2 \alpha + 2s \cos \alpha \cos \beta + t \cos^2 \beta$, $p \cos \alpha + q \cos \beta = \cos \gamma$, $r x_1^2 + 2s x_1 y_1 + t y_1^2 = \pm r$, $p x_1 + q y_1 = z_1$, r_1 and q_1 being the same quantities we have hitherto represented by r and q . The two last will be in the present hypothesis the two equations of the plane curve drawn in the tangent plane. Since the first of these two equations contains only the two coordinates x_1 and y_1 , it represents the projection of the curve on the plane of x, y , and as this equation belongs either to an ellipse, to two conjugate hyperbolas, to a system of two parallel lines, or to a system of two straight lines passing through the point (x, y, z) , it may be assumed that the curve in question will present the same circumstances.

As to the principal radii of curvature, they will be determined by means of the formula $x_1 dx_1 + y_1 dy_1 + z_1 dz_1 = 0$, from which the quantities dx_1, dy_1, dz_1 must be eliminated by means of the differential equations

$$(r x_1 + s y_1) dx_1 + (s x_1 + t y_1) dy_1 = 0, p dx_1 + q dy_1 = dz_1.$$

But if we first eliminate dz_1 between the first and the third of the three last equations, we find $(x_1 + p z_1) dx_1 + (y_1 + q z_1) dy_1 = 0$; and this being compared to the second equation gives

$$\frac{r x_1 + s y_1}{x_1 + p z_1} = \frac{s x_1 + t y_1}{y_1 + q z_1} = \frac{x_1(r x_1 + s y_1) + y_1(s x_1 + t y_1)}{x_1(x_1 + p z_1) + y_1(y_1 + q z_1)}$$

and then, since we have $r x_1^2 + 2s x_1 y_1 + t y_1^2 = \pm r_1$, $p x_1 + q y_1 = z_1$ and $\rho = x_1^2 + y_1^2 + z_1^2$, we shall get

$$\frac{r x_1 + s y_1}{(1 + p^2) x_1 + p q y_1} = \frac{s x_1 + t y_1}{(1 + q^2) y_1 + p q x_1} = \pm \frac{r_1}{\rho} = q_1;$$

or, which is the same thing,

$$[r - (1 + p^2) q_1] x_1 + (s - p q q_1) y_1 = 0, (s - p q q_1) x_1 + \{t - (1 + q^2) q_1\} y_1 = 0. \dots (a).$$

To obtain from these formulæ the value of q_1 , it is sufficient to eliminate x_1 and y_1 . We shall find thus,

$$(r - (1 + p^2) q_1) \{t - (1 + q^2) q_1\} - (s - p q q_1)^2 = 0, \text{ or } (1 + p^2 + q^2) q_1^2 - \{ (1 + p^2) t - 2 p q s + (1 + q^2) r \} q_1 + r t - s^2 = 0.$$

We have besides, $\frac{1}{\rho} = \pm \frac{q_1}{\sqrt{1 + p^2 + q^2}}$, and by combining the equation (a) with the equation $p x_1 + q y_1 = z_1$,

we find

$$\frac{x_1}{s - p q q_1} = \frac{y_1}{(1 + p^2) q_1 - r} = \frac{z_1}{p s - q r + q q_1} = \frac{\rho^{\frac{1}{2}} \sqrt{1 + p^2}}{\sqrt{\{ (1 + p^2) s - p q r \}^2 + (1 + p^2 + q^2) [(1 + p^2) q_1 - r]^2}};$$

Integral Calculus. and, consequently,

$$\frac{\cos \alpha}{s - p q q_1} = \frac{\cos \beta}{(1 + p^2) q_1 - r} = \frac{\cos \gamma}{p s - q r + q q_1} = \pm \frac{\sqrt{(1 + p^2)}}{\sqrt{\{(1 + p^2) s - p q r\}^2 + (1 + p^2 + q^2) [(1 + p^2 + q^2) q_1 - r]^2}}.$$

The two values of q_1 derived from the equation of the second degree, found above, are

$$q_1 = \frac{(1 + p^2) t - 2 p q s + (1 + q^2) r \pm \sqrt{\{(1 + p^2) t - 2 p q s + (1 + q^2) r\}^2 - 4 (1 + p^2 + q^2) (r t - s^2)}}{2 (1 + p^2 + q^2)}.$$

But the quantity under the radical is identically equal to

$$\frac{\{(1 + p^2) [(1 + p^2) t - (1 + q^2) r] + 2 p q [p q r - (1 + p^2) s]^2\} + 4 (1 + p^2 + q^2) [p q r - (1 + p^2) s]^2}{(1 + p^2)^2};$$

it follows that the two values of q_1 are essentially real. When $r t - s^2 > 0$, the equation from which those two values are derived shows that these values are of the same sign. Therefore in that case the two principal radii of curvature are in the same direction, and represent a maximum and a minimum of the variable ρ . If we had $r t - s^2 < 0$, the two values of q_1 would have contrary signs, and the principal radii of curvature would have opposite directions, and represent two minima of the variable ρ . Lastly, if we had $r t - s^2 = 0$ one of the values of $q_1 = 0$, and the maximum value of ρ becomes infinite; therefore the curvature of one of the principal sections would be equal to nothing, that is to say, that one of the principal sections would be a straight line. This takes place in each point of a *surface développable*; consequently, the values of r, s, t derived from the equation of such a surface will verify the formula $r t - s^2 = 0$, whatever be the values of x, y, z .

The two values of q_1 become equal in the case where the quantity under the radical becomes equal to nothing. This cannot take place unless we have, at the same time, $p q r - (1 + p^2) s = 0$, and $(1 + p^2) t - (1 + q^2) r = 0$,

or which is the same thing, $\frac{r}{1 + p^2} = \frac{s}{p q} = \frac{t}{1 + q^2}$. But in this case $q_1 = \frac{r}{1 + p^2} = \frac{s}{p q} = \frac{t}{1 + q^2}$. Therefore

all the values of the variables q_1 and ρ_1 become equal. In the same supposition the values of $\cos \alpha, \cos \beta, \cos \gamma$ become indeterminate.

In order that the principal radii of curvature should be equal and in opposite directions, it is necessary that the coefficient of the first power of q_1 should be equal to nothing, or $(1 + p^2) - 2 p q s + (1 + q^2) r = 0$.

It was Euler who first established the theory of the curvature of surfaces, and showed the relations which exist between the radii of curvature of the several sections made in a surface by normal planes. (See *Mémoires de l'Académie de Berlin*, 1760.)

(367.) We shall investigate now the values of the radii of curvature of the curves which may be drawn upon a given surface,

Let $u = 0$ be the equation of the surface, and let us suppose that on this surface a curve is drawn, passing through the point, the coordinates of which are represented by x, y, z . If s be the length of the arc of this curve, and ρ its radius of curvature corresponding to the point x, y, z , the cosines of the angles formed by this radius with

the axes of coordinates will be according to (316.) $\rho \frac{d^2 x}{d s^2}, \rho \frac{d^2 y}{d s^2}, \rho \frac{d^2 z}{d s^2}$. If through the same point (x, y, z) we

draw a normal to the surface, and if, for brevity sake, we suppose $r = \sqrt{\left\{\left(\frac{d u}{d x}\right)^2 + \left(\frac{d u}{d y}\right)^2 + \left(\frac{d u}{d z}\right)^2\right\}}$ the cosines of the angles formed by the normal, produced in a certain direction, and the axes will be respectively $\frac{1}{r} \frac{d u}{d x}, \frac{1}{r} \frac{d u}{d y}, \frac{1}{r} \frac{d u}{d z}$. Let now δ be the angle formed by the direction of the normal with the direction of the

radius of curvature, we shall have

$$\cos \delta = \frac{\rho}{r} \frac{\frac{d u}{d x} \frac{d^2 x}{d s^2} + \frac{d u}{d y} \frac{d^2 y}{d s^2} + \frac{d u}{d z} \frac{d^2 z}{d s^2}}{d s^2}.$$

Let, also, α, β, γ be the angles which the tangent to the curve forms with the three axes, we shall have, in making

$$q = \frac{d^2 u}{d x^2} \cos^2 \alpha + \frac{d^2 u}{d y^2} \cos^2 \beta + \frac{d^2 u}{d z^2} \cos^2 \gamma + 2 \frac{d^2 u}{d y d z} \cos \beta \cos \gamma + 2 \frac{d^2 u}{d z d x} \cos \gamma \cos \alpha + 2 \frac{d^2 u}{d x d y} \cos \beta \cos \alpha,$$

$$\frac{d u}{d x} \frac{d^2 x}{d s^2} + \frac{d u}{d y} \frac{d^2 y}{d s^2} + \frac{d u}{d z} \frac{d^2 z}{d s^2} = - q d s^2,$$

and, consequently,

$$\cos \delta = \frac{\rho}{r} q, \text{ or } \frac{\cos \delta}{\rho} = - \frac{q}{r}, \text{ or } \rho = - \frac{r}{q} \cos \delta.$$

The quantity r contained in the right side of this equation depends only on the position of the point (x, y, z) on the surface; the quantity q depends not only on this position but also on the direction of the tangent to the curve drawn upon the surface; and δ represents one of the two angles formed by the osculating plane of the curve, or,

Integral Calculus. which is the same thing, the angle formed by the principal normal to the curve with the normal to the surface. Part III. This understood, it is obvious that if together with the point, (x, y, z) the tangent to the curve and the osculating plane are given, the quantities q and r will be known, as well as the numerical value of $\cos \delta$, and the radius

of curvature will be determined by the above formula $\rho = -\frac{r}{q} \cos \delta$. Hence, since the quantities ρ and r are

quantities which are essentially positive, we may conclude that $\cos \delta$ and q will always be quantities of different signs. This remark will enable us to determine first the sign of $\cos \delta$, and consequently in what direction, on the principal normal, the radius of curvature should be taken.

From what precedes, results, first, that, if two curves drawn on the same surface through the same point, have at that point the same osculating plane, they will also have the same radius of curvature; secondly, that if these two curves have the same tangent without having the same osculating plane, their radii of curvature will be proportional to the cosines of the angles which their principal normals form with the normal to the surface. In the particular case where the osculating plane of a curve becomes a normal plane to the surface upon which the curve is drawn, we have $\cos \delta = \pm 1$, the sign being determined by the direction of the radius of curvature; and

we have therefore $\rho = \mp \frac{r}{q}$, which is the same formula we have already obtained in (363.) By comparing this value

of ρ with the general value $\rho' = -\frac{r}{q} \cos \delta$, we obtain a theorem which may be stated in the following manner.

Any curve whatever being drawn on a surface, if through the tangent to this curve, at a given point, (x, y, z) we conceive a normal plane to the surface, the radius of curvature of the curve will be equal to the product of the radius of curvature of the section corresponding to the normal plane, by the cosine of the angle formed by that plane and the osculating plane of the curve.

It is easy to verify the preceding theorem in several simple cases. Thus, for instance, if through a given point on a sphere, a great circle and a small circle are drawn, having, at that point, the same tangent, it is obvious that the radius of the small circle is equal to the radius of the sphere multiplied by the cosine of the acute angle formed by the two planes.

Let us consider for a second example the surface generated by the revolution, round the axis of x , of a curve drawn in the plane of x, y , and represented by the equation $y = f(x)$; and let it be required to find the radius of curvature ρ , corresponding to the point (x, y, z) in the curve of intersection of that surface, and of a normal plane to it, drawn through that point, perpendicularly to the generating curve passing through the same point. The acute angle which this normal plane makes with the plane passing through the point (x, y, z) perpendicularly to the axis of x , will clearly be equal to the angle τ of the generating curve, at the point (x, y, z) with the axis of x . Therefore, since the intersection of the second plane with the surface of revolution will be a circle, the radius of this circle will be equal to $\rho \cos \tau$. It is obvious, moreover, that this radius is equal in length to the ordinate $f(x)$ of the generating curve, and consequently, we shall have $\rho \cos \tau = \pm f(x)$; or, since

$$\cos \tau = \frac{1}{\sqrt{1 + (f'(x))^2}}, \quad \rho = \pm f(x) \sqrt{1 + (f'(x))^2},$$

which is a formula already obtained in Example 2. (365.)

Let us suppose now the equation of the surface resolved with respect to z , and reduced to the form $z = f(x, y)$, then if we assume $df(x, y) = p dx + q dy$, and $d^2f(x, y) = r dx^2 + 2s dx dy + t dy^2$, we shall have,

according to the preceding formulæ $\frac{\cos \delta}{\rho} = \frac{r \cos^2 \alpha + 2s \cos \alpha \cos \beta + t \cos^2 \beta}{\sqrt{1 + p^2 + q^2}}$, when δ will be the angle included

between the radius ρ and the normal, this normal being produced in such a manner as to form with the axis the angles λ, μ, ν , determined by the equations

$$\cos \lambda = \frac{p}{\sqrt{1 + p^2 + q^2}}, \quad \cos \mu = \frac{q}{\sqrt{1 + p^2 + q^2}}, \quad \cos \nu = \frac{r}{\sqrt{1 + p^2 + q^2}}.$$

(368.) Two surfaces are said to have a point of osculation, when, having a common point, they have at that point, not only the same tangent plane, but also their principal sections, for that point, contained in the same normal planes, and their principal radii of curvature equal, and in the same direction.

This understood, if we conceive any plane passing through the point of osculation of two surfaces, it is easy to conclude from what has been demonstrated in the preceding paragraph, that the two curves of intersection of that plane with the two surfaces, will have, at their common point, the same radii of curvature. Consequently the

formula $\frac{r \cos^2 \alpha + 2s \cos \alpha \cos \beta + t \cos^2 \beta}{\sqrt{1 + p^2 + q^2}}$ will have the same value for both surfaces, for any values of α and β

which satisfy the equation $\cos^2 \alpha + \cos^2 \beta + (p \cos \alpha + q \cos \beta)^2 = 1$. Moreover, the two surfaces having the same tangent plane at their common point, the quantities p and q , and consequently the denominator $\sqrt{1 + p^2 + q^2}$ will be the same for both surfaces; hence, the numerator $r \cos^2 \alpha + 2s \cos \alpha \cos \beta + t \cos^2 \beta$ must retain the same value for both surfaces; and as for the supposition $\cos \alpha = 0$, this numerator is reduced to $t \cos^2 \beta$, and for the supposition $\cos \beta = 0$, to $r \cos^2 \alpha$; it is easy to see that r, t , and s must have the same values for both surfaces. Therefore two surfaces, represented by two equations between rectangular coordinates

Integral
Calculus.

x, y, z have a point of osculation, the values $z, p = \frac{dz}{dx}, q = \frac{dz}{dy}, r = \frac{d^2z}{dx^2}, s = \frac{d^2z}{dx dy}, t = \frac{d^2z}{dy^2}$, have for the

coordinates of the common point, the same values in both surfaces. In general, the inverse of this proposition is obviously true; however, it might not be so, if the values of some of the quantities, p, q, r, s, t , were infinite.

(369.) From the preceding number, and from what has been demonstrated (363.), it clearly results, that in order that a point belonging to two surfaces should be a point of osculation, it is sufficient, 1. that the two surfaces should have, at that point, the same tangent plane; 2. that the conic section drawn on the tangent plane, any radius vector of which is equal to the radius of curvature of the normal section, made in the first surface, through the same radius vector of the conic section, should coincide with the analogous curve drawn on the same tangent plane, corresponding to the second surface. But a conic section is completely determined when the centre is known, as well as three lines drawn from the centre to three points of the curve. Moreover, when the radius of curvature of the curve of intersection of a surface by an oblique plane passing through one of its points is known, it is easy to find the radius of curvature of the normal section, which has the same tangent, at that point, as the preceding curve, and, consequently, the length of the radius vector for one of the points of the above-mentioned conic section. Hence, in order that the common point of two surfaces, which have at that point the same tangent plane, should be a point of osculation, it is sufficient that this point should be a point of osculation of the three pairs of curves of intersection of the surfaces by any three planes drawn through the same point. This condition will be satisfied, for instance, if the radii of curvature of the sections made in the first and second surfaces by three planes parallel to the coordinates planes are the same in length and direction.

(370.) Let $u = 0, v = 0$ be the equations of two curve surfaces, we shall have, by differentiating successively with respect to x and y , $\frac{du}{dx} + \frac{du}{dz} \frac{dz}{dx} = 0, \frac{du}{dy} + \frac{du}{dz} \frac{dz}{dy} = 0$; and by differentiating again each of these equations with respect to x and y ,

$$\begin{aligned} \frac{d^2u}{dx^2} + 2 \frac{d^2u}{dx dz} \frac{dz}{dx} + \frac{d^2u}{dz^2} \left(\frac{dz}{dx}\right)^2 + \frac{du}{dz} \frac{d^2z}{dx^2} &= 0, \\ \frac{d^2u}{dx dy} + \frac{d^2u}{dy dz} \frac{dz}{dx} + \frac{d^2u}{dx dz} \frac{dz}{dy} + \frac{d^2u}{dz^2} \frac{dz}{dx} \frac{dz}{dy} + \frac{du}{dz} \frac{d^2z}{dx dy} &= 0, \\ \frac{d^2u}{dy^2} + 2 \frac{d^2u}{dy dz} \frac{dz}{dy} + \frac{d^2u}{dz^2} \left(\frac{dz}{dy}\right)^2 + \frac{du}{dz} \frac{d^2z}{dy^2} &= 0; \end{aligned}$$

or, which is the same thing,

$$\begin{aligned} \frac{du}{dx} + p \frac{du}{dz} &= 0, & \frac{du}{dy} + q \frac{du}{dz} &= 0, & \frac{d^2u}{dx^2} + 2p \frac{d^2u}{dx dz} + p^2 \frac{d^2u}{dz^2} + q \frac{du}{dz} &= 0, \\ \frac{d^2u}{dy^2} + 2q \frac{d^2u}{dy dz} + q^2 \frac{d^2u}{dz^2} + t \frac{du}{dz} &= 0, & \frac{d^2u}{dx dy} + p \frac{d^2u}{dy dz} + q \frac{d^2u}{dx dz} + pq \frac{d^2u}{dz^2} + s \frac{du}{dz} &= 0 \end{aligned}$$

and, consequently,

$$\begin{aligned} p &= -\frac{\left(\frac{du}{dx}\right)}{\left(\frac{du}{dz}\right)}, & q &= -\frac{\left(\frac{du}{dy}\right)}{\left(\frac{du}{dz}\right)}, & r &= -\frac{\frac{d^2u}{dx^2} \left(\frac{du}{dz}\right)^2 - 2 \frac{d^2u}{dx dz} \frac{du}{dz} + \frac{d^2u}{dz^2} \left(\frac{du}{dx}\right)^2}{\left(\frac{du}{dz}\right)^3}, \\ s &= -\frac{\frac{d^2u}{dx dy} \left(\frac{du}{dz}\right)^2 - \frac{d^2u}{dy dz} \frac{du}{dz} \frac{du}{dx} - \frac{d^2u}{dx dz} \frac{du}{dy} \frac{du}{dz} + \frac{d^2u}{dz^2} \frac{du}{dx} \frac{du}{dy}}{\left(\frac{du}{dz}\right)^3}, \\ t &= -\frac{\frac{d^2u}{dy^2} \left(\frac{du}{dz}\right)^2 - 2 \frac{d^2u}{dy dz} \frac{du}{dz} \frac{du}{dy} + \frac{d^2u}{dz^2} \left(\frac{du}{dy}\right)^2}{\left(\frac{du}{dz}\right)^3}. \end{aligned}$$

By substituting v for u in these formulæ we shall have the values of p, q, r, s, t for the second surface, and by equalling those last values to the preceding five equations which will express the conditions which ought to be satisfied in order that the point (x, y, z) should be a point of osculation of the two surfaces.

(371.) When two curves in space have a common point, and have, at that point, a common tangent, they are said, as it has already been stated, to touch each other. Now the contact between two curves in space which touch each other, is said to be of various degrees or orders according to circumstances we are going to examine, and which are analogous to those which establish the different orders of contact between two plane curves, and which have been discussed (291.) and following.

If from the point of contact of two curves in space, touching each other, as a centre, with an infinitely small radius, the length of which shall be designated by i , we conceive a sphere to be described, the surface of this

Part III.
Integral
Calculus.

Part III.

sphere will meet the two curves in two points very near each other. The distance of these two points will be the distance of the two curves at a distance i of the point of contact. This distance is clearly measured by the chord of the arc of a great circle of the described sphere, contained between the two curves. The radii drawn from the centre of the sphere to the extremities of this small arc will include a small angle, which we shall call w , and each of these radii will form a very small angle with the common tangent to both curves. The arc of the great circle, above mentioned, will be equal to $i w$, and the chord to $2 i \sin \frac{w}{2}$.

It is obvious now that the less the length of the chord $2 i \sin \frac{w}{2}$ is, the nearer to each other will be the two curves at the distance i from the point of contact. But the degree of smallness of the chord $2 i \sin \frac{w}{2}$, for the same value of i , will depend on the degree of smallness of $\sin \frac{w}{2}$, or of w . Hence, it is natural to take the degree of smallness of w , considered as a function of i , to indicate the order of contact of the two curves.

Let us then suppose that w , considered as a function of i , is an infinitely small quantity of the order α . Since

the ratio $\frac{\sin \frac{1}{2} w}{\frac{1}{2} w}$ has unity for its limit, the product $w \cdot \frac{\sin \frac{w}{2}}{\frac{w}{2}} = 2 \sin \frac{w}{2}$, will also be an infinitely small quantity

of the order α , and consequently the expressions $i w$, and $2 i \sin \frac{w}{2}$, infinitely small quantities of the order $\alpha + 1$.

We shall, therefore, say, that the order of contact of two curves in space, which touch each other at a point P , is less by one than the order of the infinitely small quantity which represents the distance between two points Q and R , situated on the two curves, at equal distances from the point of contact, and the distance of which to that point is an infinitely small quantity of the first order.

It is necessary to remark, that the line $Q R$, being the base of an isosceles triangle, opposite to the very small angle w of that triangle, will nearly be perpendicular to the sides $P Q$, $P R$, and consequently to the common tangent to the two curves. It is also obvious that the surface of this small triangle is equal to $\frac{i^2}{2} \sin w$, that is to an infinitely small quantity of the order $\alpha + 2$.

Let us imagine now that the two curves and the triangle $P Q R$ are projected on a plane not very nearly perpendicular to the plane of the triangle $P Q R$. The projections of the two curves will have a common tangent, and therefore will touch each other. Let the three points which are the projections of P , Q , and R be denoted by $P' Q' R'$. Let δ be the angle of the two planes $P Q R$, $P' Q' R'$, and ϕ , χ , and ψ be the angles which the lines $P Q$, $P R$, $Q R$ make respectively with their projections $P' Q'$, $P' R'$, $Q' R'$. We shall have

$$P' Q' = P Q \cos \phi = i \cos \phi, \quad P' R' = P R \cos \chi = i \cos \chi, \quad Q' R' = Q R \cos \psi = 2 i \sin \frac{w}{2} \cos \psi,$$

and also by a well-known theorem, the surface of

$$P' Q' R' = P Q R \cos \delta = \frac{1}{2} i^2 \sin w \cos \delta = i^2 \sin \frac{1}{2} w \cos \frac{1}{2} w \cos \delta.$$

Moreover, the sine of the angle $P' Q' R'$ is equal to the double of the surface of the triangle $P' Q' R'$ divided by the rectangle $P' Q' \times Q' R'$ of the sides including the angle. Hence, $\sin P' Q' R' = \frac{\cos \frac{1}{2} w \cos \delta}{\cos \phi \cos \psi}$, and the product of this sine by the line $P' Q'$, or the length of the perpendicular drawn from the P' on the line $Q' R'$, will be represented by $\frac{i \cos \frac{1}{2} w \cos \delta}{\cos \psi}$. But the value of w being very small, and those of the angles ϕ , χ , ψ ,

being sensibly different from $\frac{\pi}{2}$, the quantities $\cos \frac{1}{2} w$, $\cos \delta$, $\cos \phi$, $\cos \chi$, $\cos \psi$, will have values which will not be infinitely small. Consequently, the line $Q' R'$ will be an infinitely small quantity of the order $\alpha + 1$, the angle $P' Q' R'$, which it forms with the line $P' Q'$, will be sensibly different from nothing, and the distance of the point P' to the line $Q' R'$ an infinitely small quantity of the first order. Besides, the common tangent to the projections of the two curves will nearly coincide with the line $P' Q'$, and will therefore form with the secant $Q' R'$ a finite angle. Consequently, the projections of the two curves will have, as well as the curves in space, a contact of the order α .

If the plane of the triangle $P' Q' R'$ were sensibly perpendicular to the plane of the triangle $P Q R$, and if, at the same time, the angles of the lines $P Q$, $P R$, and, consequently, the angle of the common tangent to the two curves with this same plane $P' Q' R'$, were sensibly different from nothing, the projections of the two curves on the plane $P' Q' R'$ would have a constant of an order equal or superior to α . For then, the distances $P' Q'$, $P' R'$, would still be infinitely small quantities of the first order, and the distance $Q' R'$ an infinitely small quantity of the order $\alpha + 1$, or of a superior order. If, therefore, in this hypothesis, we imagine that a sphere be described having P' for its centre, and $P' Q'$ for its radius, and that it cut the projection of the second curve in a point s' ,

Integral
Calculus.

the line $R'S'$ will very nearly be parallel to the common tangent to the projections of the two curves in space, since its two extremities will be situated on one of these curves at infinitely small distances from P' . On the contrary, the line $Q'S'$, basis of the small isosceles triangle $P'Q'S'$, will nearly be perpendicular to the same tangent. Therefore the triangle $Q'R'S'$ will nearly be right-angled at S' , and consequently the line $Q'S'$ nearly equal to $Q'R' \cos R'Q'S'$, that is to say, to an infinitely small quantity of the order $a+1$, or even of an order superior to that number; and, hence, the order of contact of the two projections will be equal or superior to the number a .

Let us suppose now that the two curves in space are projected on the planes of the x, y , and x, z , and, moreover, that the angle of the common tangent to the curves and the axis of x differs sensibly from a right angle. This tangent will then be neither nearly perpendicular to the plane of x, y , nor to the plane of x, z . These coordinate planes, besides, cannot be at the same time nearly perpendicular to the plane of the triangle PQR , for if it were so, their line of intersection, that is to say the axis of x , would necessarily form an angle nearly equal to 90° with the lines PQ, PR , and, consequently, with the common tangent to the two curves. This understood, it results from the principles above established, that the contact of the projections of the two curves on the plane of the x, y , and that of the projections of the two curves on the plane of the x, z , will always be of the order a , or of an order superior to the number a , and on one of the two coordinate planes, at least, of an order equal to a .

Hence, to obtain the order of contact of two curves which touch each other in a point where the common tangent to the two curves does not form a right angle with the axis of x , it is sufficient to find the numbers which indicate the orders of contact of the projections of the two curves on the planes of x, y , and on the plane of x, z . Each of these numbers, if they be equal, or the smallest of the two, if they be unequal, will indicate the order of contact of the two curves in space. This is equally true whether x, y, z represent rectangular or oblique coordinates.

(372.) Let us suppose that two curves, each represented by two equations between the three rectangular or oblique coordinates x, y, z , have a common point, corresponding to the abscissa x , and, at that point, a common tangent not perpendicular to the axis of x , with a contact of the order a . Let us, moreover, take x for the independent variable, and let $y', y'', y''', \&c.$, and $z', z'', z''', \&c.$, designate the successive derived functions of y and z , considered as functions of x . Then, according to the preceding principles, and to what has been before stated with respect to the contact of two plane curves, the quantities $y, y', y'', \dots y^{(n)}, z, z', z'', \dots z^{(n)}$, will assume the same values, for the value of x , corresponding to the point of contact in both curves, n being equal to a , or the integer immediately superior to a , whilst the values of $y^{(n+1)}$, and $z^{(n+1)}$, or at least the values of one of them, will be different.

Hence, when the common tangent to the two curves is not perpendicular to the axis of x , and that it is known that the order of contact is an integer, it is sufficient to determine this order to find the greatest value which can be taken for n , in choosing this number in such a manner that the values of the quantities $y, y', y'', \dots y^{(n)}, z, z', z'', \dots z^{(n)}$, corresponding to the abscissa of the point of contact, should be the same in passing from one curve to the other. This value of n precisely indicates the required order of contact. If the common tangent to the two curves formed a right angle with the axis of x , it could not be, at the same time, perpendicular to the plane of x, y , and to the plane of x, z . Consequently, it would form an angle differing from 90° with the axis of y , and with the axis of z , or, at least, with one of these two axes. Therefore to find, in this hypothesis, the order of contact of the two given curves, it would be sufficient to substitute the axis of y , or the axis of z for the axis of x , and the plane of y, z for the plane of x, z or x, y .

(373.) The order of contact of two curves may also be obtained by a different process, which has on the preceding the advantage of presenting no restriction.

Let P be the common point of the two curves which touch each other. Let also Q and R be two other points situated on the first and second curve, at equal distances from the point of contact, which distance is infinitely small and represented by i . Moreover, from the point P , on the second curve, let an arc PS be taken, having the same length and direction as the arc PQ , and terminating at a point S . The secant QS , as well as the secant QR , will nearly be perpendicular to the common tangent; and the chord RS nearly be parallel to the same tangent. Consequently, in the triangle QRS , the sides QR and QS will form angles with the third side RS which will very little differ from a right angle. Therefore the ratio between the two first sides, or, which is the same thing, the ratio between the sines of the opposite angles, will very little differ from one, and, designating by I an infinitely small quantity, we shall have $QS = QR(1 + I) = (1 + I) 2i \sin \frac{w}{2}$. But the limit of

the ratio between the arc PQ and the chord PQ is also equal to one, therefore if j designate another infinitely small quantity we shall have $\text{arc } PQ = (1 + j)i$. This understood, let us suppose that the two curves have a contact of the order a , and that i is an infinitely small quantity of the first order. It is clear that the arc PQ will also be an infinitely small quantity of the first order, whilst the distance QS will be an infinitely small quantity of the order $a+1$; and the order of this distance will not vary, if we suppose that the arc PQ , or a quantity such as the arc PQ , remains an infinitely small quantity of the first order.

Hence, to obtain the order of contact of two curves which touch each other. It suffices to find the number which represents the order of the infinitely small distance, between the extremities of two equal lengths taken on the two curves from the point of contact, in the case where these same lengths become infinitely small quantities of the first order. This number minus one indicates in every case the order of contact.

Let i be the infinitely small quantity which represents each of the two equal lengths above mentioned. Let x, y, z , and x_1, y_1, z_1 , be the coordinates of the extremities of those lengths, and l the length of the line which joins

Integral Calculus. them. Then $l = \sqrt{(x - x_1)^2 + (y - y_1)^2 + (z - z_1)^2}$. If i be an infinitely small quantity of the first order, and if α be the order of contact of the two curves, according to (371.) l will be an infinitely small quantity of the order $\alpha + 1$, and consequently, $l^2 = (x - x_1)^2 + (y - y_1)^2 + (z - z_1)^2$ an infinitely small quantity of the order $2\alpha + 2$. Therefore each of the differences $x - x_1, y - y_1, z - z_1$ must be infinitely small quantities of the order $\alpha + 1$, or, at least, one of them, the others being then infinitely small quantities of higher orders. The same conclusion results also from the remark that the quantities $x - x_1, y - y_1, z - z_1$, are the projections of l on the three axes, and that, generally, an infinitely small distance and its projection on any axis whatever are quantities of the same order, only the order of the projection may be higher than the order of the distance in the case where that distance is nearly perpendicular to the axis, and it is obvious that this circumstance cannot occur at the same time for the three axes of x, y, z .

Let n represent the integer equal or immediately superior to α . Then since i being considered as an infinitely small quantity of the first order, one of the three differences $x - x_1, y - y_1, z - z_1$, must be of the order $\alpha + 1$; the two others being of the same or of an higher order, it follows that if we take i for the independent variable.

$$x - x_1, \frac{d(x - x_1)}{di}, \frac{d^2(x - x_1)}{di^2}, \dots, \frac{d^n(x - x_1)}{di^n}, \quad y - y_1, \frac{d(y - y_1)}{di}, \frac{d^2(y - y_1)}{di^2}, \dots, \frac{d^n(y - y_1)}{di^n},$$

$$z - z_1, \frac{d(z - z_1)}{di}, \frac{d^2(z - z_1)}{di^2}, \dots, \frac{d^n(z - z_1)}{di^n},$$

will vanish with the quantity i , whilst, on the contrary, each of the quantities

$$\frac{d^{n+1}(x - x_1)}{di^{n+1}}, \quad \frac{d^{n+1}(y - y_1)}{di^{n+1}}, \quad \frac{d^{n+1}(z - z_1)}{di^{n+1}},$$

or at least one of them, will not vanish for $i = 0$. Let s and s_1 be the arcs of the first and second curve beginning at the point of contact, and terminating respectively at the points x, y, z , and x_1, y_1, z_1 . Let us also suppose that these arcs are in the same direction as the arc i . Since the three variables i, s , and s_1 , will differ from each other by constant quantities, we shall have $di = ds = ds_1$, and, with respect to the first curve, we may take for the independent variable s instead of i , and with respect to the second curve s_1 instead of i . This understood, the quantities written above, which were said to vanish for $i = 0$, will become

$$x - x_1, \frac{dx}{ds} - \frac{dx_1}{ds_1}, \frac{d^2x}{ds^2} - \frac{d^2x_1}{ds_1^2}, \dots, \frac{d^nx}{ds^n} - \frac{d^nx_1}{ds_1^n}, \quad y - y_1, \frac{dy}{ds} - \frac{dy_1}{ds_1}, \frac{d^2y}{ds^2} - \frac{d^2y_1}{ds_1^2}, \dots, \frac{d^ny}{ds^n} - \frac{d^ny_1}{ds_1^n},$$

$$z - z_1, \frac{dz}{ds} - \frac{dz_1}{ds_1}, \frac{d^2z}{ds^2} - \frac{d^2z_1}{ds_1^2}, \dots, \frac{d^nz}{ds^n} - \frac{d^nz_1}{ds_1^n},$$

and

$$\frac{d^{n+1}x}{ds^{n+1}} - \frac{d^{n+1}x_1}{ds_1^{n+1}}, \quad \frac{d^{n+1}y}{ds^{n+1}} - \frac{d^{n+1}y_1}{ds_1^{n+1}}, \quad \frac{d^{n+1}z}{ds^{n+1}} - \frac{d^{n+1}z_1}{ds_1^{n+1}}.$$

In making each of the differences in the first line equal to nothing, we shall form the equations

$$x = x_1, \quad \frac{dx}{ds} = \frac{dx_1}{ds_1}, \quad \frac{d^2x}{ds^2} = \frac{d^2x_1}{ds_1^2}, \dots, \frac{d^nx}{ds^n} = \frac{d^nx_1}{ds_1^n}, \quad y = y_1, \quad \frac{dy}{ds} = \frac{dy_1}{ds_1}, \quad \frac{d^2y}{ds^2} = \frac{d^2y_1}{ds_1^2}, \dots, \frac{d^ny}{ds^n} = \frac{d^ny_1}{ds_1^n},$$

$$z = z_1, \quad \frac{dz}{ds} = \frac{dz_1}{ds_1}, \quad \frac{d^2z}{ds^2} = \frac{d^2z_1}{ds_1^2}, \dots, \frac{d^nz}{ds^n} = \frac{d^nz_1}{ds_1^n},$$

which must be verified by the coordinates of the point of contact of the two given curves, whilst, for the same point, each of the three differences between the partial differential coefficients of the order $n + 1$, or, at least, one of them, must obtain a value different from zero.

Hence we may conclude that, when two curves have a common point, and touch each other at that point, if the coordinates x, y, z , of each of them be considered as functions of the arc s , taken for the independent variable, and if we suppose that this arc s is taken on each curve, in such a manner that its prolongation beyond the point of contact be in the same direction in both cases; not only for that point of contact, the variables x, y, z , and

their first differential coefficients $\frac{dx}{ds}, \frac{dy}{ds}, \frac{dz}{ds}$, will not change their values in passing from the first curve to the

second, but it will also be the same thing with respect to the differential coefficients $\frac{d^2x}{ds^2}, \frac{d^2y}{ds^2}, \frac{d^2z}{ds^2}, \dots, \frac{d^2y}{ds^2}, \frac{d^2z}{ds^2}, \dots$

$\frac{d^3x}{ds^3}, \frac{d^3y}{ds^3}, \frac{d^3z}{ds^3}, \dots$, up to that the order of which will be indicated by the integer equal or immediately superior to the order of contact. These differential coefficients will be the last which will verify the above-stated condition, so that the three following of the next order, or at least one of the three following, will change value in passing from one curve to another.

Hence, without repeating almost the whole of the preceding paragraph, it is easy to see what will happen when the two curves will have a contact of the n^{th} order, n designating an integer.

(374.) Let $r = f(x, y, z)$ be any function whatever of the three variables x, y, z . If we consider these variables as functions of s , r will also be a function of s , and we shall find

Integral
Calculus.

$$\begin{aligned}\frac{dr}{ds} &= \frac{d \cdot f(x, y, z)}{dx} \cdot \frac{dx}{ds} + \frac{d \cdot f(x, y, z)}{dy} \cdot \frac{dy}{ds} + \frac{d \cdot f(x, y, z)}{dz} \cdot \frac{dz}{ds}, \\ \frac{d^2 r}{ds^2} &= \frac{d \cdot f(x, y, z)}{dx} \frac{d^2 x}{ds^2} + \frac{d \cdot f(x, y, z)}{dy} \frac{d^2 y}{ds^2} + \frac{d \cdot f(x, y, z)}{dz} \frac{d^2 z}{ds^2} + \frac{d^2 f(x, y, z)}{dx^2} \cdot \frac{dx^2}{ds^2} + \frac{d^2 f(x, y, z)}{dy^2} \cdot \frac{dy^2}{ds^2} \\ &\quad + \frac{d^2 f(x, y, z)}{dz^2} \cdot \frac{dz^2}{ds^2} + \frac{2 d^2 f(x, y, z)}{dy dz} \cdot \frac{dy dz}{ds^2} + \frac{2 d^2 f(x, y, z)}{dx dz} \cdot \frac{dx dz}{ds^2} + \frac{2 d^2 f(x, y, z)}{dy dx} \cdot \frac{dy dx}{ds^2}, \\ &\dots\dots\dots \\ \frac{d^n r}{ds^n} &= \frac{d \cdot f(x, y, z)}{dx} \cdot \frac{d^n x}{ds^n} + \frac{d \cdot f(x, y, z)}{dy} \cdot \frac{d^n y}{ds^n} + \frac{d \cdot f(x, y, z)}{dz} \cdot \frac{d^n z}{ds^n} + \&c.\end{aligned}$$

From these equations, and what precedes, it easily results, that if the two curves have a contact of the n^{th} order, each of the quantities

$$r = f(x, y, z), \quad \frac{dr}{ds} = \frac{df(x, y, z)}{ds}, \quad \frac{d^2 r}{ds^2} = \frac{d^2 \cdot f(x, y, z)}{ds^2}, \dots, \quad \frac{d^n r}{ds^n} = \frac{d^n \cdot f(x, y, z)}{ds^n},$$

will have the same values, for the point of contact, in passing from one curve to the other. It is what will happen, for instance, if we take for r the radius drawn from the origin of coordinates to the point x, y, z ; in which case $r = \sqrt{(x^2 + y^2 + z^2)}$. At the same time the value of $\frac{d^{n+1} r}{ds^{n+1}} = \frac{d^{n+1} f(x, y, z)}{ds^{n+1}}$, determined by the equation

$$\frac{d^{n+1} f(x, y, z)}{ds^{n+1}} = \frac{d \cdot f(x, y, z)}{dx} \cdot \frac{d^{n+1} x}{ds^{n+1}} + \frac{d \cdot f(x, y, z)}{dy} \cdot \frac{d^{n+1} y}{ds^{n+1}} + \frac{d \cdot f(x, y, z)}{dz} \cdot \frac{d^{n+1} z}{ds^{n+1}} + \&c.$$

will generally change in passing from one curve to the other, because this will be the case for at least one of the quantities $\frac{d^{n+1} x}{ds^{n+1}}, \frac{d^{n+1} y}{ds^{n+1}}, \frac{d^{n+1} z}{ds^{n+1}}$. Nevertheless, the contrary might take place in some particular cases,

of, for instance, the values of x, y, z , relative to the point of contact, reduced to nothing, in the value of $\frac{d^{n+1} r}{ds^{n+1}}$, the coefficients of the three above coefficients of the $n+1^{\text{th}}$ order, or, at least, the coefficient of that, among the three, the value of which changes in passing from one curve to the other. The same remark applies to the differential

coefficients $\frac{d^{n+2} r}{ds^{n+2}}, \frac{d^{n+3} r}{ds^{n+3}}$.

(375.) Let us suppose now that it is required to take r instead of s for the independent variable. Then we may conceive that the coordinates x, y, z , being always functions of s , s becomes a function of r ; and we shall obtain by successive differentiations of the equation $r = f(x, y, z)$,

$$\begin{aligned}1 &= \frac{df(x, y, z)}{ds} \cdot \frac{ds}{dr}, \quad 0 = \frac{d \cdot f(x, y, z)}{ds} \cdot \frac{d^2 s}{dr^2} + \frac{d^2 f(x, y, z)}{ds^2} \cdot \left(\frac{ds}{dr}\right)^2, \\ &\&c. \\ 0 &= \frac{d \cdot f(x, y, z)}{ds} \cdot \frac{d^n s}{dr^n} + \&c.\end{aligned}$$

These formulæ, combined with the preceding rule to find the order of contact of two curves in space, show that if these curves have a contact of the n^{th} order, the quantities $\frac{ds}{dr}, \frac{d^2 s}{dr^2}, \&c. \dots, \frac{d^n s}{dr^n}$, will have the same values for the coordinates of the point of contact in passing from one curve to the other. If, therefore, we substitute the values of these quantities in the following formulæ,

$$\begin{aligned}\frac{dx}{dr} &= \frac{dx}{ds} \cdot \frac{ds}{dr}, \quad \frac{d^2 x}{dr^2} = \frac{dx}{ds} \cdot \frac{d^2 s}{dr^2} + \frac{d^2 x}{ds^2} \cdot \left(\frac{ds}{dr}\right)^2, \quad \&c. \dots, \quad \frac{d^n x}{dr^n} = \frac{dx}{ds} \cdot \frac{d^n s}{dr^n} + \&c., \\ \frac{dy}{dr} &= \frac{dy}{ds} \cdot \frac{ds}{dr}, \quad \frac{d^2 y}{dr^2} = \frac{dy}{ds} \cdot \frac{d^2 s}{dr^2} + \frac{d^2 y}{ds^2} \cdot \left(\frac{ds}{dr}\right)^2, \quad \&c. \dots, \quad \frac{d^n y}{dr^n} = \frac{dy}{ds} \cdot \frac{d^n s}{dr^n} + \&c., \\ \frac{dz}{dr} &= \frac{dz}{ds} \cdot \frac{ds}{dr}, \quad \frac{d^2 z}{dr^2} = \frac{dz}{ds} \cdot \frac{d^2 s}{dr^2} + \frac{d^2 z}{ds^2} \cdot \left(\frac{ds}{dr}\right)^2, \quad \&c. \dots, \quad \frac{d^n z}{dr^n} = \frac{dz}{ds} \cdot \frac{d^n s}{dr^n} + \&c.,\end{aligned}$$

it will become evident that, if the two curves have a contact of the order n , and if we take $r = f(x, y, z)$ for the independent variable, not only the coordinates x, y, z , but also their derived functions,

$$\frac{dx}{dr}, \frac{d^2 x}{dr^2}, \dots, \frac{d^n x}{dr^n}, \quad \frac{dy}{dr}, \frac{d^2 y}{dr^2}, \dots, \frac{d^n y}{dr^n}, \quad \frac{dz}{dr}, \frac{d^2 z}{dr^2}, \dots, \frac{d^n z}{dr^n},$$

will have the same values, corresponding to the point of contact, in passing from one curve to the other. It is, however, necessary to exclude from this result some particular cases, which might occur, and in which the values

Integral
Calculus.

Part III.

of the above derived functions would present themselves, for both curves, under the form $\frac{0}{0}$, or $\frac{\infty}{\infty}$, and would,

however, vary in passing from one curve to the other. In every other case the variable r may be, as it has just been demonstrated, substituted to the variable s . Only, it is necessary to remark, that it is not possible then to affirm

that, for the point of contact, one, at least, of the three differential coefficients, $\frac{d^{n+1}x}{dr^{n+1}}$, $\frac{d^{n+1}y}{dr^{n+1}}$, $\frac{d^{n+1}z}{dr^{n+1}}$, will change value in passing from one curve to the other.

(376.) Supposing again that the order of contact of the two curves is n , and that r is taken for the independent variable, let p, q , &c. represent new functions of the coordinates x, y, z . We shall have

$$\begin{aligned}\frac{dp}{dr} &= \frac{dp}{dx} \cdot \frac{dx}{dr} + \frac{dp}{dy} \cdot \frac{dy}{dr} + \frac{dp}{dz} \cdot \frac{dz}{dr}, \\ \frac{d^2p}{dr^2} &= \frac{dp}{dx} \cdot \frac{d^2x}{dr^2} + \frac{dp}{dy} \cdot \frac{d^2y}{dr^2} + \frac{dp}{dz} \cdot \frac{d^2z}{dr^2} + \frac{d^2p}{dx^2} \cdot \frac{dx^2}{dr^2} + \frac{d^2p}{dy^2} \cdot \frac{dy^2}{dr^2} + \frac{d^2p}{dz^2} \cdot \frac{dz^2}{dr^2} \\ &\quad + 2 \frac{d^2p}{dydz} \cdot \frac{dydz}{dr^2} + 2 \frac{d^2p}{dzdx} \cdot \frac{dzdx}{dr^2} + 2 \frac{d^2p}{dxdy} \cdot \frac{dxdy}{dr^2}, \\ &\text{&c.} \dots \dots \dots\end{aligned}$$

$$\frac{d^n p}{dr^n} = \frac{dp}{dx} \frac{d^n x}{dr^n} + \frac{dp}{dy} \frac{d^n y}{dr^n} + \frac{dp}{dz} \frac{d^n z}{dr^n} + \text{&c.}$$

Hence it is obvious that, in passing from one curve to the other, the differential coefficients $\frac{dp}{dr}, \frac{d^2p}{dr^2}, \dots, \frac{d^n p}{dr^n}$,

and even the differentials $dp, d^2p, \dots, d^n p$, will have the same values. Similar conclusions would be obtained by substituting the function q for the function p . We might also take p or q for the independent variable. Thus, for instance, we might prove, that the differentials $dq, d^2q, \dots, d^n q$, and $dr, d^2r, \dots, d^n r$, taken with respect to p considered as the independent variable, do not vary, for the coordinates of the point of contact, in passing from one curve to the other.

If we suppose $r = x, p = y, q = z$, these last conditions would become identical with those found above.

We may now remark, that it is always possible to choose the axis of x in such a manner as it should form with the common tangent to the two curves an angle differing from a right angle. This understood, from what has been demonstrated in the last paragraphs, and from what has been stated (311.), it readily follows that if a curve have a contact of the second order, or of a higher order, with another curve, each of them is an osculating curve of the other, and reciprocally that two curves which have an osculation have a contact, at least of the second order.

(377.) Let us consider now two curved surfaces which touch each other at a point P . If through this point we imagine a normal plane to the two surfaces, the two lines of intersection will be tangents to each other; and if we imagine this plane to turn round the normal, the two lines will generally change both their position and form. As to the number which will represent the order of contact of these two lines, it may remain constantly the same, or change value with the position of the normal plane. Now, this number, when it is constant, or its minimum value, in the contrary case, is used to measure what is called the order of contact of the two surfaces. Let a be this order; and let us suppose that the two surfaces being cut by any plane passing through the normal, Q and R represent the points where the curves of intersection are met by an arc of a circle having P for its centre, and an infinitely small quantity of the first order, designated by i , for its radius. The distance QR , which varies with the position of the normal plane, will be an infinitely small quantity, the order of which will be equal to a constant or variable number, the minimum of which will be $a + 1$.

Let us conceive now that through the point Q , situated on the first surface, a secant is drawn in a direction parallel to a line which forms with the plane, tangent at both surfaces, an angle δ having a value sensibly different from 0, but inferior, or at most equal to $\frac{\pi}{2}$. Let us, moreover, suppose, that this secant meets the other surface

in a point s . In the triangle QRS , the side RS will nearly be parallel to the tangent plane, since it joins two points of the second surface, situated very near the point of contact. Hence it will form with the sides QR, QS , finite angles, the first of which will very little differ from a right angle, whilst the second will be equal or superior to δ . Therefore, if we designate by I an infinitely small quantity, and by Δ an angle greater

than δ , and less than 90° , we shall have $QS = \frac{\sin(\frac{\pi}{2} + I)}{\sin \Delta} QR$. From this last formula it results that the

infinitely small distance QS will be, for all the positions of the normal plane, of the same order as the distance QR . Moreover, since the ratio between the perpendicular drawn from the point P on the line QS and the line $PQ = i$ will be the sine of the angle PQS , formed by the line QS with a line PQ sensibly parallel to the tangent plane, and consequently a finite quantity, this perpendicular will clearly be an infinitely small quantity of the first order. From these various remarks the following proposition is readily deduced.

The order of contact of two surfaces which touch each other at a point P , is inferior by one unity to the value or to the minimum value of the number which represents the order of the infinitely small distance of the points Q and S , where those surfaces are met by a secant, which forms with the tangent plane, common to the two

surfaces, a finite angle, the distance of the point of contact to that secant being considered as an infinitely small quantity of the first order.

(378.) Let us suppose now that a plane passing through the point P forms a finite angle with the tangent plane. The intersections of this plane with the two surfaces will be two new curves. We may imagine that the secant above mentioned, coincides with a line situated in this same plane, and then it will easily follow, that when two surfaces have, at a given point, a contact of the order a , the intersections with both surfaces of every normal or oblique plane which forms a finite angle with the tangent plane, common to both surfaces, are two curves which have a contact of the order a , or of a superior order.

It is important to remark here, that not only the two sections above mentioned may have a contact of an order much higher than the number a , but that even, in certain cases, they may coincide. Then the number which represents the order of contact of the two sections becomes infinite. These two sections, in some cases, are reduced to one straight line. We may take as an instance the straight line common to two conical or cylindrical surfaces which touch each other.

(379.) If the two surfaces are represented by two equations between the coordinates x, y, z , and if the tangent plane drawn through the point of contact of the two surfaces is not very nearly parallel to the axis of z , then supposing the secant QS parallel to this same axis, we shall immediately conclude the following proposition.

To obtain the order of contact of two surfaces which touch each other at a given point where the tangent plane to the two surfaces is not parallel to the axis of z , it is sufficient to draw an ordinate very near the point of contact, and to find the value, or the minimum value of the number constant, or variable, which represents the order of the infinitely small portion of ordinate contained between the two surfaces, supposing that the distance of the point of contact to that ordinate is considered as an infinitely small quantity of the first order. This value, or this minimum value decreased by one order indicates the order of contact.

Let $z = f(x, y)$ and $z = F(x, y)$ be the equations of the two curved surfaces. They will have a common point corresponding to a system of given values of the variables x, y , and, at that point, a tangent plane common to both, not parallel to the axis of z , if for the proposed values of x and y the equations $z = f(x, y)$ and $z = F(x, y)$ give equal and finite values, not only for the ordinate z , but also for its partial differential coefficients $p = \frac{dz}{dx}$, $q = \frac{dz}{dy}$, so that the equations

$$f(x, y) = F(x, y), \quad \frac{df(x, y)}{dx} = \frac{dF(x, y)}{dx}, \quad \frac{df(x, y)}{dy} = \frac{dF(x, y)}{dy},$$

should be verified, and that both sides of each should take finite values. In this hypothesis the difference $F(x, y) - f(x, y)$ will vanish for the values of x and y relative to the point of contact, and will become infinitely small when the variables x and y will receive infinitely small increments $\Delta x, \Delta y$; and if we consider the distance $\sqrt{(\Delta x)^2 + (\Delta y)^2}$ as being an infinitely small quantity of the first order, the order of the infinitely small quantity which will represent the new value of $F(x, y) - f(x, y)$ will be higher by one unity than the order of contact of the two surfaces. It is necessary, moreover, to remark that the expression $\sqrt{(\Delta x)^2 + (\Delta y)^2}$ will be an infinitely small quantity of the first order, if each of the increments $\Delta x, \Delta y$, is an infinitely small quantity of that order, or if one of them be of that order, the other being nothing or of a higher order.

If the two surfaces touch each other in a point of the axis of z , but in such a manner that the axis of z should not be contained in the tangent plane drawn through the point of contact, it will be sufficient, according to what has just been stated, to determine the order of contact, to find the number which indicates the order of the difference $F(x, y) - f(x, y)$, in considering the two variables x and y as infinitely small quantities of the first order and to diminish this number by one. By operating according to this method, it will be easy to ascertain that the four surfaces represented by the four equations $z = x^2 + y^2$, $z = x^3 + y^3$, $z = x^2 + y^3$, $z = x^3 + y^2$, have at the origin of coordinates a contact of the first order, whilst, at the same point, the two surfaces $z = x^n + y^n$, $z = x^{n+1} + y^{n+1}$, have a contact of the order n , and the two surfaces $z = x^{\frac{5}{3}} + y^{\frac{5}{3}}$, $z = x^{\frac{5}{4}} + y^{\frac{5}{4}}$, a contact of the order $\frac{5}{4} - 1 = \frac{1}{4}$.

Let us suppose, again, that the two surfaces have, in a common point, the coordinates of which are x and y , the same tangent plane, not parallel to the axis of z , with a contact of the order a , and let, besides, n be the integer equal or immediately superior to a . The difference $F(x, y) - f(x, y)$ will vanish; and, if we designate by Δx and Δy infinitely small increments of the first order, given to the coordinates x and y , the expression $F(x + \Delta x, y + \Delta y) - f(x + \Delta x, y + \Delta y)$ will be an infinitely small quantity of the order $a + 1$. In order that the increments Δx and Δy should be infinitely small, it is sufficient to take $\Delta x = \alpha dx$, $\Delta y = \alpha dy$, α designating an infinitely small quantity of the first order, and to give to dx and dy finite values. Then we shall have $F(x + \alpha dx, y + \alpha dy) - f(x + \alpha dx, y + \alpha dy)$, an infinitely small quantity of the order $a + 1$, whatever be the values given to dx and dy . Let us suppose, for the sake of brevity,

$$F(x + \alpha dx, y + \alpha dy) - f(x + \alpha dx, y + \alpha dy) = \psi(\alpha).$$

Then $\psi^{n+1}(\alpha)$ will be the first of the derived functions $\psi(\alpha)$, $\psi'(\alpha)$, $\psi''(\alpha)$, &c. which will not vanish at the same time as α . We shall have, therefore, $\psi(0) = 0$, $\psi'(0) = 0$, $\psi''(0) = 0 \dots \psi^{(n)}(0) = 0$. But we have, for the coordinates of the point of contact,

$$\psi(0) = F(x, y) - f(x, y), \quad \psi'(0) = dF(x, y) - df(x, y), \quad \psi''(0) = d^2F(x, y) - d^2f(x, y), \quad \&c. \dots \psi^{(n)}(0) = d^n F(x, y) - d^n f(x, y).$$

Integral
Calculus.

Therefore, for the coordinates of the point of contact of the two surfaces, we shall have

Part III.

$$F(x, y) = f(x, y), \quad dF(x, y) = df(x, y), \quad d^2F(x, y) = d^2f(x, y), \quad \&c. \dots d^n F(x, y) = d^n f(x, y),$$

or which is the same thing,

$$F(x, y) = f(x, y), \quad \frac{dF(x, y)}{dx} dx + \frac{dF(x, y)}{dy} dy = \frac{df(x, y)}{dx} dx + \frac{df(x, y)}{dy} dy,$$

$$\frac{d^2F(x, y)}{dx^2} dx^2 + 2 \frac{d^2F(x, y)}{dx dy} dx dy + \frac{d^2F(x, y)}{dy^2} dy^2 = \frac{d^2f(x, y)}{dx^2} dx^2 + 2 \frac{d^2f(x, y)}{dx dy} dx dy + \frac{d^2f(x, y)}{dy^2} dy^2,$$

$$\&c. \dots$$

$$\frac{d^n F(x, y)}{dx^n} dx^n + \frac{n}{1} \frac{d^n F(x, y)}{dx^{n-1} dy} dx^{n-1} dy + \dots + \frac{d^n F(x, y)}{dy^n} dy^n = \frac{d^n f(x, y)}{dx^n} dx^n$$

$$+ \frac{n}{1} \frac{d^n f(x, y)}{dx^{n-1} dy} dx^{n-1} dy + \dots + \frac{d^n f(x, y)}{dy^n} dy^n.$$

 Since these last formulæ must be verified whatever be the finite values given to dx and dy , they will obviously lead to the following equations,

$$F(x, y) = f(x, y), \quad \frac{dF(x, y)}{dx} = \frac{df(x, y)}{dx}, \quad \frac{dF(x, y)}{dy} = \frac{df(x, y)}{dy}, \quad \frac{d^2F(x, y)}{dx^2} = \frac{d^2f(x, y)}{dx^2},$$

$$\frac{d^2F(x, y)}{dx dy} = \frac{d^2f(x, y)}{dx dy}, \quad \frac{d^2F(x, y)}{dy^2} = \frac{d^2f(x, y)}{dy^2}, \quad \&c. \dots \frac{d^n F(x, y)}{dx^n} = \frac{d^n f(x, y)}{dx^n},$$

$$\frac{d^n F(x, y)}{dx^{n-1} dy} = \frac{d^n f(x, y)}{dx^{n-1} dy}, \quad \dots \frac{d^n F(x, y)}{dx dy^{n-1}} = \frac{d^n f(x, y)}{dx dy^{n-1}}, \quad \frac{d^n F(x, y)}{dy^n} = \frac{d^n f(x, y)}{dy^n}.$$

Consequently when two surfaces touch each other at a point where the tangent plane to both surfaces is not parallel to the axis of z , not only, for that point, the ordinate z considered as a function of the two independent variables x and y , and its partial differential coefficients of the first order $\frac{dz}{dx}, \frac{dz}{dy}$, have the same values in passing from one curve to the other, but the same thing takes place with respect to the partial differential coefficients

$$\frac{d^2z}{dx^2}, \frac{d^2z}{dx dy}, \frac{d^2z}{dy^2}, \frac{d^3z}{dx^3}, \frac{d^3z}{dx^2 dy}, \frac{d^3z}{dx dy^2}, \frac{d^3z}{dy^3}, \dots$$

up to these the order of which is an integer equal or immediately superior to the order of contact. In other words, if we designate by n this integer, the ordinate z and its total differentials of all the orders up to the order n , that is to say, the quantities $dz, d^2z, d^3z, \&c. \dots d^nz$, will have the same values in passing from one surface to the other, whatever be the values given to the differentials dx, dy of the independent variables.

(380.) If, the two surfaces having a contact of the order a , the tangent plane were parallel to the axis of z , then by giving to the values of the coordinates x, y , relative to the point of contact, infinitely small increments of the first order, the difference $F(x, y) - f(x, y)$ would not generally be found an infinitely small quantity of the order $a + 1$. Nevertheless we might still determine the order of contact by the method we have made use of, in substituting one of the variables x or y for the variable z . Thus, for instance, to show that the two surfaces $z = x^{\frac{1}{3}}(1 - y^2)^{\frac{1}{3}}, z = x^{\frac{1}{4}}(1 - y^2)^{\frac{1}{4}}$, which touch the plane of y, z , at the origin of coordinates, have, at that point, a contact of the second order, it is sufficient to remark that the two equations resolved with respect to x assume the forms $x = \frac{z^3}{1 - y^2}, x = \frac{z^4}{1 - y^2}$, and that the difference $\frac{z^4}{1 - y^2} - \frac{z^3}{1 - y^2}$, is an infinitely small quantity of the third order, when y and z are considered as infinitely small quantities of the first order. As to the difference $F(x, y) - f(x, y)$, it is reduced in this example to $x^{\frac{1}{4}}(1 - y^2)^{\frac{1}{4}} - x^{\frac{1}{3}}(1 - y^2)^{\frac{1}{3}}$, and when we consider x and y as infinitely small quantities of the first order, it is an infinitely small quantity, not of the second order, but of the order $\frac{1}{4}$ only.

(381.) When the tangent plane to both surfaces is not parallel to the axis of z , and the order of contact is an integer, it suffices to determine this order to find which is the last of the equations

$$F(x, y) = f(x, y), \quad dF(x, y) = df(x, y), \quad d^2F(x, y) = d^2f(x, y), \quad \&c.$$

which is verified for the point of contact, independently of the values given to dx and dy . The order of the total differentials contained in this last equation, will be precisely the order required.

The axis of z may always be chosen so as not to be parallel to the tangent plane drawn through the point of contact of the two surfaces. This understood, from what precedes it results that, generally, when a surface has with another a contact of the second or a higher order, one of them is always an osculating surface of the other; and reciprocally when two surfaces have a point of osculation, they have at that point, at least a contact of the second order.

(382.) The principal object of the preceding pages has been to show the application of Differential Calculus to Geometry. But it is only, as it may have been observed, those geometrical questions which relate to the position of lines and surfaces with respect to each other, that Differential Calculus can be instrumental to resolve. To that other and most important part of Geometry, which has for its object to measure lines, surfaces, and bulks, Differential Calculus can be of little use, but to that part, on the contrary, Integral Calculus can be applied with the greatest advantage. These applications will form the subject of the following pages.

We shall first propose a curve being given by its equation, or equations, to find the length of any portion of it contained between two given points.

Let the curve be a plane curve, represented by an equation between the rectangular coordinates x, y , or a curve of double curvature, represented by two equations between the three rectangular coordinates x, y, z . Let s be the length of the arc contained between a point A on this curve, and another point of the curve, the abscissa of which is x ; and let it be agreed, moreover, that s will be taken with the sign $+$ or $-$ according to the side of A the length s is supposed to be taken on the curve. If τ represent the angle of the curve with the axis of x , at the extremity of the arc s , we shall have $ds = \pm \sec \tau dx$, the first sign being taken when the arc s increases at the same time as the abscissa x , and the second sign in the contrary case. This understood, let P and Q be two points of the curve, respectively determined, the first by the coordinates x_0, y_0 , and the second by the coordinates x_1, y_1 . Let us also suppose that the abscissa x increases or decreases constantly from the point P to the point Q. And, finally, let s_0 and s_1 be the two values of s corresponding to $x = x_0$ and $x = x_1$. Then since $ds = \pm \sec \tau dx$, we shall have by integrating both sides of this equation, and supposing the integrals to begin with $x = x_0$,

$s - s_0 = \pm \int_{x_0}^x \sec \tau dx$, and supposing, in this last expression $x = x_1$, we get $s_1 - s_0 = \pm \int_{x_0}^{x_1} \sec \tau dx$. This formula will give the value of the arc PQ, the sign $+$ being taken when the differences $s_1 - s_0, x_1 - x_0$, have the same sign, and the sign $-$ in the contrary case. If the point P be supposed to coincide with the point A, then if we suppose the quantities $s, s_1, x - x_0, x_1 - x_0$, to be positive, the above formulæ would give $s = \int_{x_0}^x \sec \tau dx$, $s_1 = \int_{x_0}^{x_1} \sec \tau dx$. When the abscissa x is considered as the independent variable, we have

$$\sec \tau = \sqrt{1 + \frac{dy^2}{dx^2}} = \pm \frac{n}{y},$$

n being the normal. Therefore $s = \int_{x_0}^x \sqrt{1 + \frac{dy^2}{dx^2}} dx$. In the same manner for a curve of double cur-

vature, $\sec \tau = \sqrt{1 + \frac{dy^2}{dx^2} + \frac{dz^2}{dx^2}}$, and consequently $s = \int_{x_0}^x \sqrt{1 + \frac{dy^2}{dx^2} + \frac{dz^2}{dx^2}} dx$.

If the angle τ were constant, which is the case when the proposed curve is a straight line, or an helix drawn upon a cylinder the axis of which is the axis of x , then we have $s = \sec \tau \int_{x_0}^x dx = (x - x_0) \sec \tau$. But $x - x_0$ is equal to the projection of the arc s on the axis of x ; hence it appears, that when a curve, at every point, is equally inclined to the axis of x , the length of a portion of this line is equal to the product of its projection on the axis of x , by the secant of the inclination.

Let us now apply the preceding formula to a few examples.

Example 1. Let the curve be the circumference represented by the equation $x^2 + y^2 = r^2$. We shall have $n = r$, and consequently $\sec \tau = \pm \frac{n}{y} = \frac{r}{\sqrt{r^2 - x^2}}$. Therefore $s = r \int_{x_0}^x \frac{dx}{\sqrt{r^2 - x^2}} = r \left(\sin^{-1} \frac{x}{r} - \sin^{-1} \frac{x_0}{r} \right)$, a result which might easily have been foreseen.

Example 2. Let the curve be the ellipse represented by the equation $\frac{x^2}{a^2} + \frac{y^2}{b^2} = 1$; we have then

$$\frac{dy^2}{dx^2} = \frac{b^4 x^2}{a^4 y^2} = \frac{b^2 x^2}{a^2 (a^2 - x^2)}, \text{ and } \sec \tau = \sqrt{\frac{a^4 - (a^2 - b^2)x^2}{a^2 (a^2 - x^2)}}.$$

Let e be the eccentricity of that ellipse, then $ae = \sqrt{a^2 - b^2}$, and $\sec \tau = \sqrt{\frac{a^2 - e^2 x^2}{a^2 - x^2}}$. Therefore we shall have $s = \int_{x_0}^x \sqrt{\frac{a^2 - e^2 x^2}{a^2 - x^2}} dx$. If, in this last formula, we make $x_0 = 0$ and $x = a$, we have for the fourth part of the perimeter of the ellipse $s = \int_0^a \sqrt{\frac{a^2 - e^2 x^2}{a^2 - x^2}} dx$, and consequently four times that quantity for the whole perimeter. If we suppose $x = at$, we have the whole perimeter of the ellipse

$$= 4a \int_0^1 \sqrt{\frac{1 - e^2 t^2}{1 - t^2}} dt.$$

This definite integral cannot be obtained in finite terms, but various methods give the means to calculate the values of it, with as great an approximation as may be desired.

Example 3. Let the curve be the hyperbola represented by the equation $\frac{x^2}{a^2} - \frac{y^2}{b^2} = 1$, we shall have

Integral Calculus. $\sec \tau = \sqrt{\frac{(a^2 + b^2)x^2 - a^4}{a^2(x^2 - a^2)}}$. Let ϵ be the eccentricity of the curve, then $a\epsilon = \sqrt{a^2 + b^2}$, and Part III.

$\sec \tau = \sqrt{\frac{\epsilon^2 x^2 - a^2}{x^2 - a^2}}$, therefore $s = \int_{x_0}^x \sqrt{\frac{\epsilon^2 x^2 - a^2}{x^2 - a^2}} dx$. This formula is the same as that obtained for the length of an arc of ellipse, but, in the last case, the quantity ϵ is less than one, whilst in the case of the hyperbola it is greater.

Example 4. Let the curve be the parabola represented by the equation $y^2 = 2px$. We shall have $\sec \tau = \sqrt{1 + \frac{p}{2x}}$, and $s = \int_{x_0}^x \sqrt{1 + \frac{p}{2x}} dx$.

To find the value of this integral, let us make $\sqrt{1 + \frac{p}{2x}} = t$, or $x = \frac{p}{2(t^2 - 1)}$, and we shall find,

$$\begin{aligned} \int \sqrt{1 + \frac{p}{2x}} dx &= \int t dx = tx - \int x dt = tx - \frac{p}{2} \int \frac{dt}{t^2 - 1} = tx - \frac{p}{4} l \left(\frac{t-1}{t+1} \right) \\ &+ C = x \sqrt{1 + \frac{p}{2x}} - \frac{p}{4} l \left\{ \frac{\sqrt{1 + \frac{p}{2x}} - 1}{\sqrt{1 + \frac{p}{2x}} + 1} \right\} + C. \end{aligned}$$

If we suppose $x_0 = 0$, we shall have for the value of the arc of parabola contained between the summit and the point corresponding to the abscissa x ,

$$s = x \sqrt{1 + \frac{p}{2x}} - \frac{p}{4} l \left\{ \frac{\sqrt{1 + \frac{p}{2x}} - 1}{\sqrt{1 + \frac{p}{2x}} + 1} \right\}$$

Example 5. Let the curve be the logarithmic represented by the equation $y = alx$. We shall have $\tan \tau = \frac{a}{x}$, $x = a \tan \tau$, $dx = -\frac{a d\tau}{\sin^2 \tau}$. This understood, if we designate by τ_0 , the value of τ corresponding to $x = x_0$, we shall have $s = -a \int_{\tau_0}^{\tau} \frac{d\tau}{\cos \tau \sin^3 \tau}$. But we have $\frac{1}{\cos \tau \sin^3 \tau} = \frac{\cos^2 \tau + \sin^2 \tau}{\cos \tau \sin^3 \tau} = \frac{\cos \tau}{\sin^3 \tau} + \frac{1}{\cos \tau}$, and, moreover,

$$\int \frac{\cos \tau d\tau}{\sin^3 \tau} = -\frac{1}{\sin \tau} + C, \quad \int \frac{d\tau}{\cos \tau} = \int \frac{\frac{1}{2} d\tau}{\sin \left(\frac{\pi}{4} + \frac{\tau}{2} \right) \cos \left(\frac{\pi}{4} + \frac{\tau}{2} \right)} = l \tan \left(\frac{\pi}{4} + \frac{\tau}{2} \right) + C,$$

hence we shall have

$$s = a \left\{ \frac{1}{\sin \tau} - \frac{1}{\sin \tau_0} - l \tan \left(\frac{\pi}{4} + \frac{\tau}{2} \right) + l \tan \left(\frac{\pi}{4} + \frac{\tau_0}{2} \right) \right\}.$$

It would now be easy to introduce in this formula the abscissa x instead of the angle τ .

Example 6. Let us next consider the curve represented by the equation $y = a \frac{e^{\frac{x}{a}} + e^{-\frac{x}{a}}}{2}$ which is the catenary, that is, the curve formed by a heavy and flexible chain attached by its two ends. We shall have for this curve $y' = \frac{e^{\frac{x}{a}} - e^{-\frac{x}{a}}}{2}$, consequently, $\sec \tau = \frac{e^{\frac{x}{a}} + e^{-\frac{x}{a}}}{2}$, and hence

$$s = \int_0^x \frac{e^{\frac{x}{a}} + e^{-\frac{x}{a}}}{2} dx = a \frac{e^{\frac{x}{a}} - e^{-\frac{x}{a}}}{2} = ay'.$$

Moreover, it is easy to see that in this curve the point corresponding to the abscissa $x = 0$ is precisely the lowest point. Consequently, in the catenary, the length of an arc, beginning at the lowest point, is proportional to $y' = \tan \tau$, that is to say, to the trigonometrical tangent of the inclination corresponding to the extremity of the same arc.

(383.) If in the general formula $ds = \sec \tau dx$, we change x into y , we must, at the same time, change τ into $\frac{\pi}{2} - \tau$. We shall have, therefore, $ds = \pm \operatorname{cosec} \tau dy$. This understood, we shall have $s_1 - s_0 = \int_{y_0}^{y_1} \operatorname{cosec} \tau dy$ if the differences $s_1 - s_0$ and $y_1 - y_0$ are quantities of the same sign, and $s_1 - s_0 = -\int_{y_0}^{y_1} \operatorname{cosec} \tau dy$, if

Integral
Calculus.

Part III.

these same differences have contrary signs. When the curve is plane, $\operatorname{cosec} \tau = \sqrt{1 + \frac{1}{y^2}}$, and, consequently,

supposing $s_0 = 0$, we shall have $s = \int_y^y \sqrt{1 + \frac{1}{y^2}} dy$. To show an application of this last formula, let us

suppose that the arc s is the arc of a cycloid, represented by the equation $x = r \cos^{-1} \frac{r-y}{r} - \sqrt{(2ry - y^2)}$, the origin of the arc being supposed to be the origin of the coordinates. We shall have then

$$dx = \sqrt{\left(\frac{y}{2r-y}\right)} dy, \quad y' = \sqrt{\left(\frac{2r-y}{y}\right)}, \quad 1 + \frac{1}{y'^2} = \frac{2r}{2r-y},$$

$$s = \sqrt{2r} \int_0^y \frac{dy}{\sqrt{(2r-y)}} = 2\sqrt{2r} \{ \sqrt{2r} - \sqrt{2r-y} \},$$

and consequently $4r - s = 2\sqrt{2r(2r-y)}$. This last equation gives the arc s of a cycloid in function of the ordinate y , provided the extremity of the arc is situated between the origin of coordinates and the summit of the first branch of the curve. If in the value of s we suppose $y = 2r$, we shall have the value of the whole arc $= 4r$, and by doubling it, the whole length of any branch of a cycloid, between two consecutive cusps.

(384.) The formula $s_1 - s_0 = \pm \int_{s_0}^{s_1} \sec \tau dx$ is no longer exact, when it is not possible to go from one of the extremities P of the arc to the other extremity Q, without making the abscissa increase and decrease alternately. Let us suppose that $s_0, s', s'', \dots, s^{(m)}, s_1$ are values of the arc s forming a series of increasing or decreasing terms. Let us also suppose that the abscissa x increases or decreases constantly, from the extremity of s_0 to the extremity of the arc s' from this last extremity to the extremity of the arc s'' , and, finally, from the extremity of the arc $s^{(m)}$ to the extremity Q. Then the whole length of the arc P Q cannot be determined by means of the above formula, but this formula may clearly be used to determine the length of each of the differences $s' - s_0, s'' - s', \dots, s_1 - s^{(m)}$, and it will be sufficient to add them together to obtain the value of $s_1 - s_0$, that is the length of the arc P Q.

In the same manner, to apply the formula $s_1 - s_0 = \pm \int_{y_0}^{y_1} \operatorname{cosec} \tau dy$ to the determination of an arc P Q, it would be sufficient to choose the arcs $s', s'', \dots, s^{(m)}$, in such a manner that the ordinate y should continually increase or decrease from the extremity of one of these arcs to the extremity of the next.

To make an application of what precedes, let us propose to find the length of an arc s contained between the origin and any point whatever of the cycloid represented by the equation $x = \cos^{-1} \left(\frac{r-y}{r} \right) \pm \sqrt{(2ry - y^2)}$, in which the radical quantity ought to be taken with the sign $+$ or $-$ according as the angle ω , determined by the formula $\omega = \cos^{-1} \left(\frac{r-y}{r} \right)$, has for its sine a negative or positive quantity. Let us, moreover, suppose $s_0 = 0$, the arc s_1 to be a positive quantity, and the coordinates of the extremity of this arc to be designated by x_1 and y_1 . In this case, we shall take for the extremities of the arcs $s', s'', \dots, s^{(m)}$, the summits and cusps of the cycloid which are between the origin and the point (x_1, y_1) . Then, it is obvious that each of the arcs $s', s'' - s', s''' - s'', \dots, s^{(m)} - s^{(m-1)}$ will be contained between two points, one corresponding to the ordinate $y = 0$, and the other to the ordinate $y = 2r$, and the arc $s_1 - s^{(m)}$ between a point corresponding to one of these two ordinates, and the point, the coordinates of which are x_1 and y_1 . From the above equation of the curve we find

$$dx = \pm \frac{y}{\sqrt{(2ry - y^2)}} dy, \quad \frac{dy}{dx} = \pm \sqrt{\frac{2r-y}{y}}, \quad \operatorname{cosec} \tau = \sqrt{\frac{2r}{2r-y}}.$$

This understood, if we suppose that s is a positive quantity, we shall find, according to the formula

$$s_1 - s_0 = \int_{y_0}^{y_1} \operatorname{cosec} \tau dy,$$

$$s' = s''' - s'' = s^{(m)} - s^{(m-1)} = \&c. \dots = \int_0^{2r} \sqrt{\left(\frac{2r}{2r-y}\right)} dy = 4r;$$

and, according to the formula $s_1 - s_0 = \int_{y_0}^{y_1} \operatorname{cosec} \tau dy$,

$$s'' - s' = s^{(m)} - s^{(m-1)} = \&c. \dots = \int_{2r}^0 \sqrt{\left(\frac{2r}{2r-y}\right)} dy = 4r.$$

As to the value of $s_1 - s^{(m)}$ which must be determined by the first of the two last formulæ mentioned if m be an even number, and by the last if it be odd, it will be in the first case

$$s_1 - s^{(m)} = \int_0^{y_1} \sqrt{\left(\frac{2r}{2r-y}\right)} dy = 4r - 2\sqrt{[2r(2r-y)]};$$

and, in the second,

$$s_1 - s^{(m)} = - \int_{2r}^{y_1} \sqrt{\left(\frac{2r}{2r-y}\right)} dy = 2\sqrt{[2r(2r-y)]}.$$

Integral Calculus. If we add now the arcs $s', s'' - s', s''' - s'', \dots, s^{(m)} - s^{(m-1)}, s_1 - s^{(m)}$, we shall find for the even values of m , $s_1 = 4(m+1)r - 2\sqrt{2r(2r-y)}$, and for the odd values of m , $s' = 4mr + 2\sqrt{2r(2r-y)}$, results which were both easy to foresee. Part III.

(385.) When the integrals contained in the general formulæ cannot be obtained in finite terms, it is then necessary to make use of methods of approximation. One of the simplest consists in developing the values of

$\sec \tau = \sqrt{1 + \frac{dy^2}{dx^2}}$, or $\operatorname{cosec} \tau = \sqrt{1 + \frac{dx^2}{dy^2}}$ in a converging series, each term of which multiplied by dz or dy should be easily integrable. This is obtained in various cases in making use of one of the two following formulæ.

$$\sec \tau = \left(1 + \frac{dy^2}{dx^2}\right)^{\frac{1}{2}} = 1 + \frac{1}{2} \frac{dy^2}{dx^2} - \frac{1}{2} \cdot \frac{1}{4} \frac{dy^4}{dx^4} + \frac{1}{2} \cdot \frac{1}{4} \cdot \frac{3}{6} \frac{dy^6}{dx^6} - \&c.$$

$$\operatorname{cosec} \tau = \left(1 + \frac{dx^2}{dy^2}\right)^{\frac{1}{2}} = 1 + \frac{1}{2} \frac{dx^2}{dy^2} - \frac{1}{2} \cdot \frac{1}{4} \frac{dx^4}{dy^4} + \frac{1}{2} \cdot \frac{1}{4} \cdot \frac{3}{6} \frac{dx^6}{dy^6} - \&c.$$

The first of which is converging when $\frac{dy}{dx}$ is less than one, and the other when it is superior to one. Thus, for instance, by means of these formulæ, we may develop in a converging series an arc of ellipse or hyperbola, provided no point of the curve corresponding to $\frac{dy^2}{dx^2} = 1$ should be between the extremities of this arc.

(386.) Another method by means of which an arc of ellipse or hyperbola may easily be obtained, consists in developing $\sqrt{\frac{a^2 - e^2 x^2}{a^2 - x^2}}$, or $\sqrt{\frac{e^2 x^2 - a^2}{x^2 - a^2}}$, according to the increasing or decreasing powers of the eccentricity. Let us suppose first, that it is required to find the length of an arc of ellipse. If to obtain it we make use of the formula $s = \int_{x_0}^x \sqrt{\frac{a^2 - e^2 x^2}{a^2 - x^2}} dx$, it is clear that the numerical value of x will always be less than a , we may therefore suppose $x = a \cos \phi$, and if ϕ_0 be the value of ϕ corresponding to $x = x_0$, the preceding formula will become $s = -a \int_{\phi_0}^{\phi} \sqrt{1 - e^2 \cos^2 \phi} d\phi$. If now we develop according to the increasing powers of e the radical, we shall find

$$\sqrt{1 - e^2 \cos^2 \phi} = 1 - \frac{e^2}{2} \cos^2 \phi - \frac{1}{2} \cdot \frac{e^4}{4} \cos^4 \phi - \frac{1}{2} \cdot \frac{3}{4} \cdot \frac{e^6}{6} \cos^6 \phi - \frac{1 \cdot 3 \cdot 5}{2 \cdot 4 \cdot 6 \cdot 8} e^8 \cos^8 \phi - \&c.,$$

a developement which is always converging since by hypothesis e is less than one. Hence we shall find

$$s = a(\phi_0 - \phi) + \frac{e^2}{2} \int_{\phi_0}^{\phi} \cos^2 \phi d\phi + \frac{1}{2} \cdot \frac{e^4}{4} \int_{\phi_0}^{\phi} \cos^4 \phi d\phi + \frac{1 \cdot 3}{2 \cdot 4} \cdot \frac{e^6}{6} \int_{\phi_0}^{\phi} \cos^6 \phi d\phi + \&c.$$

But we have $\cos \phi = \frac{1}{2}(e^{\phi \sqrt{-1}} + e^{-\phi \sqrt{-1}})$, and also n being any integer whatever,

$$\cos 2n\phi = \frac{1}{2^{2n}}(e^{\phi \sqrt{-1}} + e^{-\phi \sqrt{-1}})^{2n},$$

or, which is the same thing,

$$\cos^{2n} \phi = \frac{1}{2^{2n-1}} \left\{ \cos 2n\phi + \frac{2n}{1} \cos (2n-2)\phi + \frac{2n(2n-1)}{1 \cdot 2} \cos (2n-4)\phi + \dots \right. \\ \left. + \frac{1}{2} \cdot \frac{1 \cdot 2 \cdot 3 \dots 2n}{1 \cdot 2 \dots n \cdot 1 \cdot 2 \dots n} \right\},$$

and in multiplying by $d\phi$, and integrating, the integral beginning with $\phi = \phi_0$, we find

$$\int_{\phi_0}^{\phi} \cos^{2n} \phi d\phi = \frac{1}{2^{2n-1}} \left\{ \frac{\sin 2n\phi - \sin 2n\phi_0}{2n} + \frac{2n \sin (2n-2)\phi - \sin (2n-2)\phi_0}{1} \right. \\ \left. + \dots + \frac{1}{2} \cdot \frac{1 \cdot 2 \cdot 3 \dots 2n}{1 \cdot 2 \dots n \cdot 1 \cdot 2 \dots n} (\phi - \phi_0) \right\}.$$

From this last expression it results that it is possible to express by means of a finite number of terms each term of the infinite series which represents the value of s and therefore to find s by means of a converging series each term of which may be calculated exactly.

It is not unnecessary to remark that in the preceding formula, the angle ϕ , determined by the equation $\cos \phi = \frac{x}{a}$, is precisely the angle included between the positive axis of x , and the radius drawn from the origin to

Integral Calculus. the point where the ordinate corresponding to the abscissa x meets the circumference of the circle which has for its diameter the transverse axis of the ellipse equal to $2a$. Part III.

If it were required to find the arc s equal to the fourth part of the whole perimeter of the ellipse, the limits of the integral relative to x would be 0 and a , and consequently those of the integral relative to ϕ , 0 and $\frac{\pi}{2}$, then the above formula gives

$$\int_0^{\frac{\pi}{2}} \cos^{2n} \phi d\phi = - \int_0^{\frac{\pi}{2}} \cos^{2n} \phi d\phi = - \frac{1}{2n} \cdot \frac{1.2.3 \dots 2n}{1.2.3 \dots n.1.2.3 \dots n} \frac{\pi}{2} = - \frac{1.2.3 \dots 2n}{(2.4 \dots 2n)(2.4 \dots 2n)} \frac{\pi}{2} \\ = - \frac{1.3.5 \dots 2n-1}{2.4.6 \dots 2n} \frac{\pi}{2},$$

and, consequently,

$$s = a \int_0^{\frac{\pi}{2}} \sqrt{1 - \epsilon^2 \cos^2 \phi} d\phi = \frac{a\pi}{2} \left\{ 1 - \left(\frac{1}{2}\epsilon\right)^2 - \frac{1}{3} \left(\frac{1}{2} \cdot \frac{3}{4}\epsilon^2\right)^2 - \frac{1}{5} \left(\frac{1.3.5}{2.4.6}\epsilon^3\right)^2 - \frac{1}{7} \left(\frac{1.3.5.7}{2.4.6.8}\epsilon^4\right)^2 - \&c. \right\}.$$

When the ellipse becomes a circle, then $\epsilon = 0$, and $s = \frac{a\pi}{2}$.

It may be remarked, that the different products included between parentheses, in the right side of this equation, are precisely the different terms which compose the developement of $(1 - \epsilon^2)^{\frac{1}{2}}$.

Let us suppose now that it is required to calculate an arc of hyperbola. Then x is always greater than a , and we shall assume $x = \frac{a}{\cos \phi}$. Designating, as before, by ϕ_0 , the value of ϕ corresponding to $x = x_0$, we shall

have $s = a \int_{\phi_0}^{\phi} \sqrt{\epsilon^2 - \cos^2 \phi} \frac{d\phi}{\cos^2 \phi}$. And by developing, according to the decreasing powers of ϵ we shall obtain the equation

$$\frac{\sqrt{\epsilon^2 - \cos^2 \phi}}{\cos^2 \phi} = \frac{\epsilon}{\cos^2 \phi} - \frac{1}{2\epsilon} - \frac{1}{2} \cdot \frac{1}{4\epsilon^3} \cos^2 \phi - \frac{1.3}{2.4} \frac{1}{6\epsilon^5} \cos^4 \phi - \frac{1.3.5}{2.4.6} \frac{1}{8\epsilon^7} \cos^6 \phi$$

the left side of which is a converging series, since, in the hyperbola, we have $\epsilon > 1$. Hence we shall find

$$s = a\epsilon [\tan \phi - \tan \phi_0] - \frac{a}{2\epsilon} (\phi - \phi_0) - \frac{1}{2} \frac{a}{4\epsilon^3} \int_{\phi_0}^{\phi} \cos^2 \phi d\phi - \frac{1.3}{2.4} \frac{a}{6\epsilon^5} \int_{\phi_0}^{\phi} \cos^4 \phi d\phi - \frac{1.3.5}{2.4.6} \frac{a}{8\epsilon^7} \int_{\phi_0}^{\phi} \cos^6 \phi d\phi - \&c.$$

We have seen above that each of the integrals remaining in this series may be expressed in finite terms, therefore we have the value of s by means of a converging series, each term of which may be easily calculated. If we suppose that the origin of the arc coincides with the summit of the hyperbola corresponding to the abscissa $x = a$, we must suppose $\phi_0 = 0$, and the formula will be simply reduced to the following:

$$s = a\epsilon \tan \phi - \frac{a}{2\epsilon^3} \phi - \frac{1}{2} \frac{a}{4\epsilon^3} \int_0^{\phi} \cos^2 \phi d\phi - \frac{1.3}{2.4} \frac{a}{6\epsilon^5} \int_0^{\phi} \cos^4 \phi d\phi - \frac{1.3.5}{2.4.6} \frac{a}{8\epsilon^7} \int_0^{\phi} \cos^6 \phi d\phi - \&c.$$

It may be remarked, that the angle ϕ is precisely the angle contained between the positive axis of x , and the radius drawn through the origin to the point where the circle, having its centre at the origin, and for radius a , is touched by a tangent which cuts the axis of x at the point, the abscissa of which is x .

Since the asymptotes of the hyperbola are represented by the equation $\frac{x^2}{a^2} - \frac{y^2}{b^2} = 0$, it is clear that if we call r the distance between the origin and a point of one of the asymptotes corresponding to the abscissa x , we shall

have $r^2 = x^2 + \frac{b^2 x^2}{a^2} = \frac{a^2 + b^2}{a^2} x^2 = \epsilon^2 x^2$, and, consequently, if we suppose x to be a positive quantity,

$r = \epsilon x = \frac{a\epsilon}{\cos \phi}$. If from the preceding value of r we subtract the arc s , determined by the above formula, we shall find

$$r - s = a\epsilon \left(\frac{\cos \phi}{\sin \phi} + \frac{1}{2\epsilon} \phi + \frac{1}{2} \frac{a}{4\epsilon^3} \int_0^{\phi} \cos^2 \phi d\phi + \frac{1.3}{2.4} \frac{a}{6\epsilon^5} \int_0^{\phi} \cos^4 \phi d\phi + \frac{1.3.5}{2.4.6} \frac{a}{8\epsilon^7} \int_0^{\phi} \cos^6 \phi d\phi + \&c. \right)$$

Integral
Calculus.

If now we suppose $\phi = \frac{\pi}{2}$, the last equation will give the value of $r - s$ corresponding to $x = \frac{a}{\cos \frac{\pi}{2}} = \infty$, that Part III.

is very nearly the difference between two very great lengths, taken, the first from the origin on the asymptote, the second on the hyperbola from the summit, in such a manner that the extremities should correspond to the same abscissa. Therefore if we call D this difference, we shall have very nearly, when x will be very large,

$$D = \frac{a\pi}{4e} \left\{ 1 + \frac{1}{2} \left(\frac{1}{2} \cdot \frac{1}{e} \right)^2 + \frac{1}{3} \left(\frac{1.3}{2.4} \cdot \frac{1}{e^3} \right)^2 + \frac{1}{4} \left(\frac{1.3.5}{2.4.6} \frac{1}{e^5} \right)^2 + \dots \right\}.$$

(387.) The determination of the length of an arc of ellipse may also be obtained by other means. We have clearly

$$\sec^2 \tau = \frac{1}{\cos^2 \tau} = \frac{e^2 x^2 - a^2}{x^2 - a^2}, \text{ and consequently, } x^2 = \frac{a^2 (1 - \cos^2 \tau)}{1 - e^2 \cos^2 \tau}, \text{ or } x = \pm \frac{a \sin \tau}{\sqrt{1 - e^2 \cos^2 \tau}},$$

$$dx = \pm \frac{a (1 - e^2) \cos \tau d\tau}{(1 - e^2 \cos^2 \tau)^{\frac{3}{2}}}, \text{ and } ds = \pm \sec \tau dx = \pm \frac{a (1 - e^2) d\tau}{(1 - e^2 \cos^2 \tau)^{\frac{3}{2}}}.$$

This understood, if we admit that, for increasing values of τ , the arc s increases in the ellipse and decreases in the hyperbola, and if we designate by τ_0 the value of τ corresponding to the origin of the arc s , we shall find for

$$\text{the ellipse } s = a (1 - e^2) \int_{\tau_0}^{\tau} \frac{d\tau}{(1 - e^2 \cos^2 \tau)^{\frac{3}{2}}}, \text{ and for the hyperbola } s = -a (1 - e^2) \int_{\tau_0}^{\tau} \frac{d\tau}{(1 - e^2 \cos^2 \tau)^{\frac{3}{2}}}.$$

The quantities under the sign of integration may be developed in converging series according to the increasing or decreasing powers of the eccentricity. If we develop, for instance, the first formula, and if we suppose the

integrals taken between the limits $\tau = 0$ and $\tau = \frac{\pi}{2}$, we shall obtain a value of s equal to the fourth part of the perimeter of an ellipse, and hence we shall find the whole perimeter P ,

$$P = 2a\pi (1 - e^2) \left\{ 1 + 3 \left(\frac{1}{2} e^2 \right) + 5 \left(\frac{1.3}{2.4} e^4 \right) + 7 \left(\frac{1.3.5}{2.4.6} e^6 \right) + \&c. \dots \right\}$$

which value, it is easy to ascertain, agrees with the value already found above.

If, in the equation $x = \frac{a^2 (1 - \cos^2 \tau)}{1 - e^2 \cos^2 \tau}$ we substitute for x its value $a \cos \phi$, we find

$$1 \cos^2 \phi - \cos^2 \tau + e^2 \cos^2 \phi \cos^2 \tau = 0,$$

and consequently, when $\cos \phi$ is a positive quantity,

$$\cos \phi = \frac{\sin \tau}{\sqrt{1 - e^2 \cos^2 \tau}}.$$

This understood, we shall have

$$d(e^2 \cos \phi \cos \tau) = d \left\{ \frac{e^2 \cos \tau \sin \tau}{\sqrt{1 - e^2 \cos^2 \tau}} \right\} = -\sqrt{1 - e^2 \cos^2 \tau} d\tau + \frac{(1 - e^2) d\tau}{(1 - e^2 \cos^2 \tau)^{\frac{3}{2}}},$$

and hence

$$(1 - e^2) \int_{\tau_0}^{\tau} \frac{d\tau}{(1 - e^2 \cos^2 \tau)^{\frac{3}{2}}} = e^2 (\cos \phi \cos \tau - \cos \phi_0 \cos \tau_0) + \int_{\tau_0}^{\tau} \sqrt{1 - e^2 \cos^2 \tau} d\tau.$$

We shall therefore be able to put the value of s under the following form :

$$s = a e^2 (\cos \phi \cos \tau - \cos \phi_0 \cos \tau_0) + a \int_{\tau_0}^{\tau} \sqrt{1 - e^2 \cos^2 \tau} d\tau.$$

This formula supposes $\tau > \tau_0$. Then the product $a \int_{\tau_0}^{\tau} \sqrt{1 - e^2 \cos^2 \tau} d\tau$, is positive, and represents the arc of the ellipse, the extremities of which correspond to the abscissæ $a \cos \tau$ and $a \cos \tau_0$. If this arc be designated by s' we shall have $s = a e^2 (\cos \phi \cos \tau - \cos \phi_0 \cos \tau_0) + s'$, or $s - s' = a e^2 (\cos \phi \cos \tau - \cos \phi_0 \cos \tau_0)$, or again if x' and x'_0 be the abscissæ of the extremities of s' , $s - s' = e^2 \frac{x x' - x_0 x'_0}{a}$.

Hence the difference which exists between two arcs of ellipse so situated that the inclinations of the tangents drawn by the extremities of one of these arcs be respectively equal to the inclinations of the two radii drawn through the centre of the ellipse to the points where the circumference described on the transverse axis as a diameter, is met by the ordinates of the extremities of the second arc, may be expressed in finite terms.

When we suppose $\tau_0 = 0$, we have clearly $\phi_0 = \frac{\pi}{2}$ and $x_0 = 0$, and we find $s - s' = e^2 \frac{x x'}{a}$, which equation is

Integral
Calculus.

the expression of a theorem discovered by Count Fagnano, an Italian Geometer. Let us observe, moreover, Part III. that, in every case, the abscissæ x and x' relative to the extremities of the arcs s and s' should verify the equation $a^4 - a^2(x^2 + x'^2) + \epsilon^2 x^2 x'^2 = 0$, which is derived from the equation $1 - \cos^2 \phi - \cos^2 \tau + \epsilon^2 \cos^2 \phi \cos^2 \tau = 0$

by putting $\frac{x}{a}$ and $\frac{x'}{a}$ for $\cos \phi$ and $\cos \tau$.

(388.) We shall next consider the quadrature of plane surfaces, that is to say, that we shall propose to find the value of a plane surface limited by curves the equations of which are given.

Let $y = f(x)$ be the equation of a plane curve referred to rectangular coordinates. Let P and Q be two points on this curve corresponding, the first to the abscissa x_0 , and the second to the abscissa x_1 ; let p be any point of the curve corresponding to the abscissa x , and let it be required to find the area included between the curve the axis of x , and the two ordinates corresponding to the abscissæ x_0 and x . This area will be a function of x , which we shall designate by u , and which will vanish for $x = x_0$. Moreover, if we suppose $x > x_0$, and if we call Δx a positive and very small increment of x , the corresponding increment of u or Δu will represent the element of surface contained between the curve, the axis of x , and the two ordinates $f(x)$, $f(x + \Delta x)$. This understood, let q be the point of the curve corresponding to the abscissa $x + \Delta x$. The ordinate of any point of the arc $p q$ will necessarily be of the form $f(x + \theta \Delta x)$, θ being a number inferior to one. Hence the ordinates of two points situated on the same arc, the one at the least distance from the axis of x , the other at the greatest distance, will be of the form $f(x + \theta_1 \Delta x)$, $f(x + \theta_2 \Delta x)$, θ_1 and θ_2 being numbers less than one. The numerical values of these ordinates will clearly represent the heights of the inscribed and circumscribed rectangles to the element of surface Δu , whilst the area of these rectangles will be measured by the numerical values of the products $\Delta x \cdot f(x + \theta_1 \Delta x)$, $\Delta x \cdot f(x + \theta_2 \Delta x)$. Hence, if we use the notation $M(a, a', a'', \&c.)$ to represent a mean quantity between the quantities $a, a', a'', \&c.$, that is to say, a quantity the value of which is greater than the least, and less than the greatest of the quantities $a, a', a'', \&c.$ we shall have,

$$\frac{\Delta u}{\Delta x} = \pm M[f(x + \theta_1 \Delta x), f(x + \theta_2 \Delta x)],$$

and taking the limits $\frac{d u}{d x} = \pm f(x) = \pm y$, or $d u = \pm y d x$. If therefore we integrate, in the supposition

that the integral begins with $x = x_0$, we shall have $u = \pm \int_{x_0}^x y d x$, and if we call u_1 , the value of u corre-

sponding to $x = x_1$, $u_1 = \pm \int_{x_0}^{x_1} y d x$. According to the hypothesis the function u increasing at the same time

as the abscissa x , it will be necessary to take the right side of the preceding formula with the sign $+$ when the ordinate $y = f(x)$ will be positive, and with the sign $-$ in the contrary case. Let us now apply this formula to some examples.

Example 1. Let the curve be the circumference represented by the equation $x^2 + y^2 = r^2$, we shall have for the positive value of y , $y = \sqrt{r^2 - x^2}$, and hence $u = \int_{x_0}^x \sqrt{r^2 - x^2} d x$. But according to the rules of integration $\int \sqrt{r^2 - x^2} = \frac{1}{2} x \sqrt{r^2 - x^2} - \frac{1}{2} r^2 \tan^{-1} \frac{\sqrt{r^2 - x^2}}{x} + \text{const.}$ If we suppose $x_0 = 0$, we shall have, therefore, $u = \frac{1}{2} x \sqrt{r^2 - x^2} + \frac{1}{2} r^2 \left(\frac{\pi}{2} - \tan^{-1} \frac{\sqrt{r^2 - x^2}}{x} \right) = \frac{1}{2} x \sqrt{r^2 - x^2} + \frac{1}{2} r^2 \tan^{-1} \frac{x}{\sqrt{r^2 - x^2}}$, or, which is the same thing, $u = \frac{1}{2} x y + \frac{1}{2} r^2 \tan^{-1} \frac{x}{y}$, a result which it is easy to verify. If in this last formula we suppose $x = r$, we must suppose at the same time $y = 0$, and the value of u becomes $\frac{\pi}{4} r^2$, therefore the whole surface of the circle is equal to πr^2 .

Example 2. Let the curve be the ellipse represented by the equation $\frac{x^2}{a^2} + \frac{y^2}{b^2} = 1$. We get for the positive value of y , $y = \frac{b}{a} \sqrt{a^2 - x^2}$, and consequently $u = \frac{b}{a} \int_{x_0}^x \sqrt{a^2 - x^2} d x$; but

$$\int \sqrt{a^2 - x^2} d x = \frac{1}{2} x \sqrt{a^2 - x^2} + \frac{1}{2} a^2 \tan^{-1} \frac{x}{\sqrt{a^2 - x^2}},$$

therefore we shall have

$$u = \frac{1}{2} \frac{b}{a} x \sqrt{a^2 - x^2} + \frac{1}{2} a b \tan^{-1} \frac{x}{\sqrt{a^2 - x^2}},$$

or, which is the same thing,

$$u = \frac{1}{2} x y + \frac{1}{2} a b \tan^{-1} \frac{b x}{a y}.$$

Part III.
Integral
Calculus.

If from the surface u we subtract the surface of the right-angled triangle, having for the two sides of the right angle x and y , that is to say, $\frac{1}{2}xy$, the remainder,

$$\frac{1}{2}ab \tan^{-1} \frac{bx}{ay} = \frac{1}{2}ab \tan^{-1} \left(\frac{\frac{x}{a}}{\frac{y}{b}} \right),$$

will represent the elliptical sector contained between the radius drawn in the direction of the positive y , and the radius drawn from the centre to the point the coordinates of which are x and y . The surface of the fourth part of the ellipse will be the value of the preceding expression of u , corresponding to $x = a$ and $y = 0$. Therefore this surface $= \frac{\pi}{4}ab$, and that of the whole ellipse will be πab .

Example 3. Let us consider the hyperbola represented by one of the equations $\frac{x^2}{a^2} - \frac{y^2}{b^2} = 1$, $\frac{y^2}{b^2} - \frac{x^2}{a^2} = 1$, a and b being two positive quantities. We shall find for the positive value of y , $y = \frac{b}{a}\sqrt{x^2 \mp a^2}$, and, consequently $u = \frac{b}{a} \int_{x_0}^x \sqrt{x^2 \mp a^2} dx$. But

$$\int \sqrt{x^2 \mp a^2} dx = \frac{1}{2}x \sqrt{x^2 \mp a^2} \mp \frac{1}{8}a^2 l \left\{ \frac{x + \sqrt{x^2 \mp a^2}}{x - \sqrt{x^2 \mp a^2}} \right\} + c.$$

Therefore if we consider the hyperbola the transverse axis of which is $2a$, and if we take $x_0 = a$, and suppose x to be a positive quantity, we shall have

$$u = \frac{1}{2} \frac{b}{a} x \sqrt{x^2 - a^2} - \frac{1}{4} ab l \left\{ \frac{x + \sqrt{x^2 - a^2}}{x - \sqrt{x^2 - a^2}} \right\},$$

or, which is the same thing,

$$u = \frac{1}{2}xy - \frac{1}{4}ab l \left(\frac{\frac{x}{a} + \frac{y}{b}}{\frac{x}{a} - \frac{y}{b}} \right) = \frac{1}{2}xy - \frac{1}{2}ab l \left(\frac{x}{a} + \frac{y}{b} \right).$$

Such is the value of the area contained between the axis of x , the ordinate y , and the arc of hyperbola the two extremities of which coincide, the first with the summit of the curve corresponding to $x = a$, and the second with the point the coordinates of which are x and y . If we subtract this area from the surface of the right-angled triangle the sides of which are x and y , the remainder,

$$\frac{1}{2}ab l \left(\frac{x}{a} + \frac{y}{b} \right) = \frac{1}{2}ab l \left(\frac{1}{\frac{x}{a} - \frac{y}{b}} \right),$$

will represent the hyperbolic sector contained between the radius drawn in the direction of the positive x , and the radius drawn from the centre to the point the coordinates of which are x and y . In the case where this last point is situated at an infinite distance, that is to say, in the case where x and y are infinite, the expression of the surface of the sector becomes also infinite.

If we designate by x_1 and y_1 the coordinates of a point of the asymptote corresponding to the branch of curve we consider, we shall have $\frac{y_1}{b} = \frac{x_1}{a}$; therefore if we suppose $y_1 = y$, we shall have $\frac{y}{b} = \frac{x_1}{a}$, and the value of the

hyperbolic sector above mentioned will become $\frac{1}{2}ab l \left(\frac{a}{x - x_1} \right) = -\frac{1}{2}ab l \left(\frac{x - x_1}{a} \right)$. Therefore this surface

is equal, but of contrary sign to half the product of the semi-axis a and b by the hyperbolic logarithm of the ratio obtained in comparing with half the transverse axis the length $x - x_1$; reckoned upon a parallel to this axis, between the curve and its asymptote.

In the case of the equilateral hyperbola, represented by the equation $x^2 - y^2 = r^2$, the surface of the hyperbolic sector would be $\frac{1}{2}r^2 l \left(\frac{x+y}{r} \right)$. If the same hyperbola were referred to its asymptotes, its equation would be

$$xy = \frac{1}{2}r^2, \text{ or } y = \frac{1}{2} \frac{r^2}{x}, \text{ and we would have } u = \frac{1}{2}r^2 \int_{x_0}^x \frac{dx}{x} = \frac{1}{2}r^2 l \frac{x}{x_0}.$$

Example 4. Let the curve be the parabola represented by the equation $y^2 = 2px$, the positive value of y will be $y = 2p^{\frac{1}{2}}x^{\frac{1}{2}}$, and we shall have therefore $u = (2p)^{\frac{1}{2}} \int_{x_0}^x x^{\frac{1}{2}} dx = \frac{2}{3}(2p)^{\frac{1}{2}}x^{\frac{3}{2}} = \frac{2}{3}xy$. Hence the area con-

tained between the axis of the parabola, an arc of this curve which has the summit for origin, and an ordinate perpendicular to the axis, is equal to the $\frac{2}{3}$ of the circumscribed rectangle. From this we may immediately conclude, that the area contained between the arc of the parabola, the tangent drawn through the summit, and a straight line parallel to the axis, has for its measure the third of the surface of the circumscribed rectangle.

Example 5. Let the curve be the parabola of the degree a represented by the equation $y = Ax^a$, A and a being two real and constant quantities. We shall have $u = A \int_0^x x^a dx = \frac{A}{a+1} x^{a+1}$ or, which is the same thing, $u = \frac{xy}{a+1}$. Hence in a parabola of the degree a the surface contained between an arc beginning at the summit

or at the point of inflexion, the tangent drawn through that point, and a straight line perpendicular to this tangent, is to the surface of the circumscribed rectangle as one to $1+a$. If a were less than one, the ratio between these two surfaces would be that of the two numbers a and $a+1$. If we suppose $a=2$, or $a=1$, this general theorem gives results already known.

Example 6. Let the curve be the logarithmic represented by the equation $y = al(x)$ in which a designates a positive and constant quantity, we shall derive from the general formula, in supposing $x_0 = 1$ and $x > 1$,

$u = a \int_1^x l x dx = a(xlx - x + 1)$. To find the area included between the negative axis of y , and the part of the logarithmic which has this axis for asymptote, we should make use of the general formula $u = \pm \int_{x_0}^{x_1} y dx$. Then by taking the left side with the sign $-$, and supposing $x_0 = 0$, and $x_1 = 1$, we would

find for the required area $u = -a \int_0^1 l x dx = a$. This area, therefore, is not infinite as that contained between the hyperbola and its asymptote; but it is equal to the number a , that is to say, that this number represents the limit of the area contained between the axis of x the part of the curve produced on the side of the negative y , and an ordinate of the same curve, supposing this ordinate to approach nearer and nearer to the axis of y .

Example 7. Let the curve be the catenary represented by the equation $y = a \frac{e^{\frac{x}{a}} + e^{-\frac{x}{a}}}{2}$. If we suppose $x_0 = 0$ we shall find $u = a^2 \frac{e^{\frac{x}{a}} - e^{-\frac{x}{a}}}{2}$. Such is the expression of the surface contained between the axis of x , the catenary, and the two ordinates a and y , corresponding to the two abscissæ 0 and x . If besides, we designate by s , the arc contained between these two ordinates, we have found before $s = a \frac{e^{\frac{x}{a}} - e^{-\frac{x}{a}}}{2}$. Consequently $u = as$. Hence

the area contained between the axis of abscissa, the arc s beginning at the lowest point, and the two ordinates of the extremities of this arc, is equal to the rectangular parallelogram, having for its base the arc s , and for its height the ordinate of the lowest point.

(389.) In several cases the valuation of surfaces may be more easily obtained by substituting for the variable x another variable. Let it be supposed that u represents the surface contained between the axis of x , and the cycloid represented by the equations $x = r(w - \sin w)$, $y = r(1 - \cos w)$. Then $dx = y dw$, and if we designate by

w_0 the value of w corresponding to $x = x_0$, we have $u = \int_{w_0}^w y^2 dw = r^2 \int_{w_0}^w (1 - \cos w)^2 dw$. Let us suppose that

the area begins at the origin of coordinates, then $w_0 = 0$, and we have

$$u = \int_0^w (1 - \cos w)^2 dw = r^2 \int_0^w (1 - 2 \cos w + \cos^2 w) dw = r^2 \int_0^w \left(\frac{3}{2} - 2 \cos w + \frac{1}{2} \cos 2w \right) dw \\ = r^2 \left\{ \frac{3}{2} w - 2 \sin w + \frac{1}{4} \sin 2w \right\}.$$

And, since w designates the angle described by the generating circle of the cycloid, it is obvious that by making $w = 2\pi$ in the last formula, we shall have the area contained between the axis of x , and the first branch of the cycloid. We find thus $u = 3\pi r^2$, therefore the area contained between the basis of the cycloid and one of the branches of the curve is equal to three times the area of the generating circle.

(390.) Let u now represent the area contained between two curves represented by the equations $y = f(x)$ and $y = F(x)$, and secondly, between the ordinates corresponding to the abscissæ x_0 and x . Then it is easy to prove that $du = \pm \{F(x) - f(x)\} dx$, the sign $+$ being taken when the difference $F(x) - f(x)$ is positive, and the sign $-$ when it is negative. If we suppose $\phi(x)$ equal to the numerical value of the difference $\pm \{F(x) - f(x)\}$,

Integral
Calculus.

we shall have $du = \phi(x) dx$, and $u = \int_{x_0}^x \phi(x) dx$. This formula is similar to that we have used before, only

$\phi(x)$ does not represent here the ordinate of a curve, but the length of the linear section made in the surface u by a plane perpendicular to the axis of x , and corresponding to the abscissa x . If the curves represented by the equations $y = f(x)$ and $y = F(x)$, intersected in two points corresponding to the abscissæ x_0 and x , then u would designate the area contained between the two curves. It would also be the area contained between the two curves, if they touch each other at the points corresponding to the abscissæ x_0 and x . Lastly, the values $y = f(x)$ and $y = F(x)$ may be two values derived from the same equation, $f(x, y) = 0$, representing a curve limited all

round. Then to derive from the formula $u = \int_{x_0}^x \phi(x) dx$ the value of the area inclosed by this curve, it will be

sufficient to substitute for x and x_0 the greatest and smallest abscissæ of the points of the curve, or, which is the same thing, the abscissæ of the two points of the axis of x which include between them the projection of the curve on this axis. In most cases, these abscissæ will be those of the points of the curve when the tangent becomes parallel to the axis of y .

Let us take for example the curve represented by the equation $x^{2m} + y^{2m} = 1$, m being any integer whatever. We shall have two values of the ordinate

$$y = -(1 - x^{2m})^{\frac{1}{2m}}, y = (1 - x^{2m})^{\frac{1}{2m}}, \text{ and consequently, } \phi(x) = 2(1 - x^{2m})^{\frac{1}{2m}}.$$

The equation of the curve gives besides $\frac{dy}{dx} = -\left(\frac{x}{y}\right)^{2m-1}$, and it is obvious that the tangent will become parallel

to the axis of y , at the points where $y = 0$, and consequently $x = -1$, or $x = +1$. It is easy to verify that these two values of x are the maximum and minimum of all the values corresponding to the different points of the

curve. This understood, we shall have for the whole area of the curve $u = 2 \int_{-1}^1 (1 - x^{2m})^{\frac{1}{2m}} dx$, or which is the same thing, $u = 4 \int_0^1 (1 - x^{2m})^{\frac{1}{2m}} dx$. If $m = 1$ the curve becomes a circle, and we find $u = \pi$.

Let us next suppose that the curve is represented by the equation $x^{\frac{2m}{2n+1}} + y^{\frac{2m}{2n+1}} = 1$. We shall have for the area inclosed by the curve $u = 2 \int_{-1}^1 \left(1 - x^{\frac{2m}{2n+1}}\right)^{\frac{2n+1}{2m}} dx$. But if we suppose m to be inferior, or at most equal, to n , we shall find that the abscissæ -1 and $+1$ belong to points where the curve presents cusps, and where the tangent, instead of being parallel to the axis of y , is parallel to the axis of x .

If we suppose $m = 1$, we find $u = 2 \int_{-1}^1 \left(1 - x^{\frac{2}{2n+1}}\right)^{\frac{2n+1}{2}} dx = 4 \int_0^1 \left(1 - x^{\frac{2}{2n+1}}\right)^{\frac{2n+1}{2}} dx$. To find this value let us suppose $x = \sin^{\frac{2n+1}{2}} \phi$, we shall get

$$u = 4(2n+1) \int_0^{\frac{\pi}{2}} \cos^{2n+2} \phi \sin^{\frac{2}{2n+1}} \phi d\phi = (8n+4) \int_0^{\frac{\pi}{2}} \cos^{(2n+2)} \phi (1 - \cos^2 \phi)^{\frac{n}{2}} d\phi;$$

developing, and making use of the formula

$$\int_0^{\frac{\pi}{2}} \cos^{2n} \phi d\phi = -\frac{1.3.5 \dots 2n-1}{2.4.6 \dots 2n} \frac{\pi}{2},$$

we find

$$u = (4n+2) \pi \left\{ \frac{1.3.5 \dots 2n+1}{2.4.6 \dots 2n+2} - \frac{n}{1} \frac{1.3.5 \dots 2n+3}{2.4.6 \dots 2n+4} + \frac{n(n-1)}{1.2} \frac{1.3.5 \dots (2n+5)}{2.4.6 \dots (2n+6)} - \&c. \right\}.$$

If we suppose at the same time $m = 1$ and $n = 1$, the equation of the curve becomes $x^{\frac{2}{3}} + y^{\frac{2}{3}} = 1$, and

$$u = \frac{3}{8} \pi.$$

(391.) It is also essential to remark, that the formula $u = \int_{x_0}^x \phi(x) dx$ is true in the case where the functions $f(x)$, $F(x)$, change their forms, so as to represent the ordinates of several curves, or even of several straight lines drawn one after the other in the plane of x, y . Let us suppose $F(x) = (1 - x^2)$, that is to say, that the first curve is the parabola represented by the equation $y = 1 - x^2$, and that $f(x)$, for negative values of x , coincides with the ordinate of the straight line $y = -\frac{3}{2}x$, and for positive values with the ordinate of the straight line represented by the equation $y = \frac{5}{6}x$. Then, for $x < 0$, we shall have $\phi(x) = 1 - x^2 + \frac{3}{2}x$, and for $x > 0$,

Integral
Calculus.

$\phi(x) = 1 - x^2 - \frac{5}{6}x$. The first value of $\phi(x)$ becomes equal to nothing for $x = -\frac{1}{2}$, and the second for $x = \frac{2}{3}$. Therefore to find the area contained between the parabola and the two straight lines on the positive side of the y , we shall have the formula

$$u = \int_{-\frac{1}{2}}^0 (1x^2 + \frac{3}{2}x) dx + \int_0^{\frac{2}{3}} (1 - x^2 - \frac{5}{6}x) dx = \frac{1}{2} - \frac{1}{24} - \frac{3}{16} + \frac{2}{3} - \frac{8}{81} - \frac{5}{27} = \frac{847}{1296}.$$

It would not be more difficult to find the area limited by the sides of a polygon, these sides being either straight or curve lines.

(392.) Lastly, let us suppose that the surface u is composed of several parts so disposed that the linear section made in this surface by a plane perpendicular to the axis of x , and corresponding to the abscissa x , is composed of several and distinct lengths represented by $f_1(x), f_2(x), f_3(x)$, &c., the first of which is contained between two given curves, the second between two other given curves, &c. If we suppose, moreover, that this surface is limited by the

ordinates corresponding to the abscissæ x_0 and x , we shall have still $u = \int_{x_0}^x \phi(x) dx$, provided we take

$\phi(x) = f_1(x) + f_2(x) + f_3(x) + \&c.$ The same remark applies when the surface u is contained by a curve limited on all sides, and so bent as to be met by the same ordinate in more than two points. Then the equation of the curve resolved with respect to y , would give for each value of x an even number of real values of x ; and after arranging these real values, according to their magnitude, it would be sufficient to subtract successively the first from the second, the third from the fourth, to obtain the quantities which have been designated above by $f_1(x), f_2(x)$, &c., that is to say, the quantities the sum of which would be designated by $\phi(x)$.

(393.) We shall now proceed to prove several propositions which are of great utility in the quadrature of plane surfaces.

1. If the linear sections made in two surfaces by a system of parallel planes are to each other in a constant ratio, the two surfaces are to each other in the same ratio.

Let us suppose that the points of each surface are referred to two rectangular axes contained in the plane of this same surface, the axis of y being moreover contained in one of the parallel planes that are under consideration. If we call $f(x)$ and $\phi(x)$ the linear sections made in these two surfaces by one of these parallel planes, that corresponding to the abscissa x , we shall have $f(x) = a\phi(x)$, a designating the constant ratio between the linear sections. Let x_0 and x_1 be the limits between which the value of x must remain in order that the plane corresponding to this abscissa, and perpendicular to the axis of x should

meet the two surfaces. Then the first surface will be represented by $\int_{x_0}^{x_1} f(x) dx$, and the second by $\int_{x_0}^{x_1} \phi(x) dx$,

but since $f(x) = a\phi(x)$, we shall have $\int_{x_0}^{x_1} f(x) dx = a \int_{x_0}^{x_1} \phi(x) dx$, which is the analytical expression of the proposition to be demonstrated.

Let us consider two curves in the plane of the x, y , the one represented by the equation $f(x, y) = 0$, and the other by the equation $f\left(x, \frac{y}{b}\right) = 0$, b designating a constant quantity. It is clear that, for each value of

the abscissa x , we shall get from the equations of the two curves values of y which will be to each other in the ratio of 1 to b . Consequently, the limits x_0 and x_1 , between which the value of x ought to remain, in order that the value of the ordinate y should be real, will be the same for both curves. If we designate by y_0, y_1, y_2, y_3 , &c., the various real values of y corresponding to an abscissa x given by the equation

$f(x, y) = 0$, those corresponding to the same abscissa given by the equation $f\left(x, \frac{y}{b}\right) = 0$, will be by_0, by_1, by_2, by_3 ,

&c. If, besides, we suppose the quantities y_0, y_1, y_2 , &c. arranged according to their magnitude, the lengths previously designated by $f_1(x), f_2(x)$, &c. will be, respectively, for the curve $f(x, y) = 0$, $y_1 - y_0, y_2 - y_1$, &c., and consequently, the linear section of the surface contained within this curve will be represented by the formula $y_1 - y_0 + y_2 - y_1 + \&c.$ In the same manner, the linear section made in the curve represented

by the equation $f\left(x, \frac{y}{b}\right) = 0$ will be represented by $b(y_1 - y_0 + y_2 - y_1 + \&c.)$ Hence the area limited by

the curve $f(x, y) = 0$ is to the area limited by the curve $f\left(x, \frac{y}{b}\right) = 0$ in the ratio of 1 to b .

By similar reasonings it may be proved, that the area limited by the curve represented by the equation $f(x, y) = 0$ is to the area limited by the curve represented by the equation $f\left(\frac{x}{a}, y\right) = 0$ in the ratio of 1 to a .

But this last area is also to the area of the curve represented by the equation $f\left(\frac{x}{a}, \frac{y}{b}\right) = 0$ in the ratio of 1 to b ,

Integral
Calculus.

Part III.

hence the area limited by the curve represented by the equation $f(x, y) = 0$ is to that limited by the curve represented by the equation $f\left(\frac{x}{a}, \frac{y}{b}\right) = 0$ in the ratio of 1 to $a b$.

Thus, for instance, the area of the ellipse represented by the equation $\frac{x^2}{a^2} + \frac{y^2}{b^2} = 1$ will be equal to $a b$ multiplied by the area of the curve represented by the equation $x^2 + y^2 = 1$, that is to $\pi a b$. In the same manner the expression we have found for the area of the curve represented by the formula $x^{\frac{2m}{2n+1}} + y^{\frac{2m}{2n+1}} = 1$ multiplied by $a b$ will be the area of the curve represented by the equation $\left(\frac{x}{a}\right)^{\frac{2m}{2n+1}} + \left(\frac{y}{b}\right)^{\frac{2m}{2n+1}} = 1$. Thus we have found for the equation of the evolute of the ellipse $\left(\frac{x}{A}\right)^{\frac{2}{3}} + \left(\frac{y}{B}\right)^{\frac{2}{3}} = 1$, in which A and B designate two quantities determined by the formula $A a = B b = \pm (a^2 - b^2)$, therefore the surface limited by this curve will be equal to $A B$ multiplied by the area of the curve represented by the equation $x^{\frac{2}{3}} + y^{\frac{2}{3}} = 1$, which we have found to be $\frac{3}{8}\pi$. Hence the area of the evolute of the ellipse is equal to $\frac{3}{8}\pi \left(\frac{a^2 - b^2}{a b}\right)^2$.

If we suppose $b = a$, then the equation $f\left(\frac{x}{a}, \frac{y}{a}\right) = 0$ is the equation of a curve similar to the curve represented by the equation $f(x, y) = 0$. Hence the areas limited by two similar curves are to each other as the squares of the linear dimensions of these curves.

Let, as in the preceding paragraph, $f(x)$ and $\phi(x)$ be the linear sections made in two surfaces, situated in the same plane, by a plane perpendicular to the axis of x , drawn at a distance x from the origin of coordinates. Let us suppose that this last plane moves, but so as to be always perpendicular to the axis of x , and that it cannot meet one of the two surfaces without meeting also the other. Let x_0 and x_1 be the limits between which the value of the abscissa x ought to remain, in order that the plane perpendicular to the axis of x should really meet the two surfaces. Then the ratio of the two surfaces contained between the ordi-

nates corresponding to the abscissæ x_0 and x_1 will be $\frac{\int_{x_0}^{x_1} f(x) dx}{\int_{x_0}^{x_1} \phi(x) dx}$. Let the integral general of $f(x) dx$,

beginning with x_0 be represented by $F(x)$, and that of $\phi(x) dx$, beginning also with x_0 , be represented by $\Phi(x)$. Then we have $\int_{x_0}^x f(x) dx = F(x)$, $\int_{x_0}^x \phi(x) dx = \Phi(x)$, and $F(x_0) = 0$, $F'(x) = f(x)$, $\Phi(x_0) = 0$, $\Phi'(x) = \phi(x)$. Consequently,

$$\frac{\int_{x_0}^{x_1} f(x) dx}{\int_{x_0}^{x_1} \phi(x) dx} = \frac{F(x_1)}{\Phi(x_1)} = \frac{F'(x_0 + \theta(x_1 - x_0))}{\Phi'(x_0 + \theta(x_1 - x_0))} = \frac{f(x_0 + \theta(x_1 - x_0))}{\phi(x_0 + \theta(x_1 - x_0))},$$

θ designating a number less than one. But it is obvious that $\frac{f(x_0 + \theta(x_1 - x_0))}{\phi(x_0 + \theta(x_1 - x_0))}$ is one of the values which the fraction $\frac{f(x)}{\phi(x)}$ may obtain for the values of x between the limits x_0 and x_1 , and therefore is a quantity contained

between the greatest and the least of these same values. Hence, the ratio of the two integrals $\int_{x_0}^{x_1} f(x) dx$, $\int_{x_0}^{x_1} \phi(x) dx$, that is of the two surfaces under consideration, is a quantity less than the greatest value of the ratio of the two linear sections $f(x)$ and $\phi(x)$ made in these two surfaces by a plane perpendicular to the axis of x , and greater than the least value of the same ratio.

If, for certain values of the abscissa, the plane perpendicular to the axis of x did not meet one of the surfaces, the last proposition might still be demonstrated, but then x_0 and x_1 ought to designate the values, which values of x ought not to exceed, in order that the plane perpendicular to the axis of x should meet one of the two surfaces, and the value of $f(x)$, or $\phi(x)$, should be considered as becoming equal to nothing for every value of x for which the plane perpendicular to the axis of x should not meet the corresponding surface.

Hence two plane surfaces are equal when a plane remaining in every position parallel to the same plane, cuts,

in every position, each of these two surfaces, so that the linear sections are equal to each other. If we suppose $\phi(x) = 1 \int_{x_0}^{x_1} \phi(x) dx = x_1 - x_0$, and consequently $\int_{x_0}^{x_1} f(x) dx = (x_1 - x_0) f(x_0 + \theta(x_1 - x_0))$. But $x_1 - x_0$

represents the linear projection of the surface on the axis of x , and $f(x_0 + \theta(x_1 - x_0))$ a mean value of $f(x)$, between the limits x_0 and x_1 . Hence the ratio between a plane area, and its projection on the axis of x , is a quantity the value of which is a mean between the various values of the linear sections made in that surface by planes perpendicular to the axis of x .

Quadrature of Curve Surfaces.

(394.) Let $z = f(x, y)$ be the equation of a curve surface referred to three rectangular coordinates. Let p be the point of the surface which has for its coordinates x, y, z , and τ be the acute angle which the tangent plane, at that point, makes with the plane of x, y . Let us suppose, that an element w of the surface, both dimensions of which are very small, and included in the point p , is projected, on the tangent plane, and on the plane of x, y . If through a point of the element w , a third plane is drawn perpendicular to the two first, the intersection of this plane with the element w will be a small arc, and with the two projections of the element two small straight lines which will be the projections of the small arc, or of the chord which joins the extremities of this arc. Now, this chord forms a very small angle with the tangent planes drawn to the surface, first through one of the extremities of the arc, and secondly through the point p , which by hypothesis is very near that extremity. If the last angle is represented by δ , the angle which the same chord will form with the plane of x, y will obviously be $\tau \pm \delta$, and, consequently, the two projections of the chord, or the linear sections made in the two projections of the element w will be to each other in the ratio of the two quantities $\cos \delta, \cos(\tau \pm \delta)$. Therefore, according to the theorem demonstrated in the last number, the projection of the element w on the plane of x, y , will have for its measure the projection of the same element on the tangent plane at the point p multiplied by a quantity less than the greatest value of the ratio $\frac{\cos(\tau \pm \delta)}{\cos \delta}$, and greater than the less value of the same

ratio. But the projection of the element w on the tangent plane may be represented by $w(1 + i)$, i designating a very small quantity, hence the projection on the plane of x, y will be represented by a product of the form $w \frac{\cos(\tau \pm \delta)}{\cos \delta} (1 + i)$. Now, the quantities i and δ being both very small, if we designate by i , a third

quantity, also very small, we shall find $\frac{\cos(\tau \pm \delta)}{\cos \tau} (1 + i) = \cos \tau + i_1$, and since the plane of x, y may be supposed to coincide with any plane whatever, the following proposition is demonstrated.

If w be an element of a curve surface, both dimensions of which are very small, and τ the acute angle formed by the tangent plane drawn through a point p of the element to the surface, and another plane, the projection of w on the last plane will be $w(\cos \tau + i_1)$, i_1 being a very small quantity.

Let now P and p be two points of the surface, the first having for its coordinates x_0 and y_0 , and the second corresponding to the coordinates of the variables x and y . If through each of the points P and p we draw two planes respectively perpendicular to the axis of x and y , the intersections of the surface with these four planes will be four curves, and the area included between these four curves will vary with the position of the point p . The projection of this area on the plane of x, y will be a rectangle, the sides of which will be equal to the numerical values of $x - x_0$ and $y - y_0$. Let $\phi(x, y)$ represent this area, and u its projection on the plane of x, y . We shall have, if we suppose $x > x_0$ and $y > y_0$, $u = (x - x_0)(y - y_0)$. Let also Δx and Δy denote very small increments of the variables x and y , and q the point of the surface corresponding to the coordinates $x + \Delta x, y + \Delta y$. Then $\phi(x + \Delta x, y + \Delta y) - \phi(x, y)$ and $\Delta x \Delta y$ will represent, the first the area of the portion of the surface included between the four planes drawn through the points p and q perpendicularly to the axis x and y , and the second the projection of the same area on the plane of x, y . Hence if τ be the acute angle formed by the tangent plane at p with the plane of x, y , we shall have

$$\Delta x \Delta y = (\cos \tau + i_1) \{ \phi(x + \Delta x, y + \Delta y) - \phi(x, y) \},$$

or

$$\frac{\phi(x + \Delta x, y + \Delta y) - \phi(x, y)}{\Delta x \Delta y} = \frac{1}{\cos \tau + i_1}.$$

If in this formula we suppose that the value of Δx and Δy decreases indefinitely, we shall have

$$\frac{d^2 \phi(x, y)}{dx dy} = \frac{1}{\cos \tau} = \sec \tau.$$

It is now easy to find the value of the area $\phi(x, y)$. This area becomes equal to nothing, at the same time as its projection on the plane of x, y , not only for $y = y_0$ whatever be the value of x , but also for $x = x_0$, whatever be the value of y . We have, therefore, generally,

$$\phi(x, y_0) = 0, \phi(x_0, y) = 0, \text{ and, consequently, } \frac{d\phi(x, y_0)}{dx} = 0, \frac{d\phi(x_0, y)}{dy} = 0.$$

Integral
Calculus.

Part III.

This understood, if we integrate the expression $\frac{d^2 \phi(x, y)}{dx dy} = \sec \tau$, first with respect to y , supposing the integral

to begin with $y = y_0$, and secondly with respect to x , supposing the integral to begin with $x = x_0$, we shall find

successively $\frac{d \phi(x, y)}{dx} = \int_{y_0}^y \sec \tau dy$, and $\phi(x, y) = \int_{x_0}^x \int_{y_0}^y \sec \tau dy dx$. If in this last formula, we substitute

for the coordinates x, y of the variable point p , the coordinates x_1, y_1 of a given point Q , situated on the surface, the value A of the area contained between the four planes drawn through the points P and Q perpendicularly to

the axis of x and y , will be $A = \int_{x_0}^{x_1} \int_{y_0}^{y_1} \sec \tau dy dx$. As to $\sec \tau$, if the differential of the equation of the

surface $z = f(x, y)$, be $dz = p dx + q dy$, we shall have $\sec \tau = \sqrt{1 + p^2 + q^2}$.

It is important to remark that in the formula representing the value of A , the order of the two integrations may be inverted.

(395.) Let us suppose now that the surface represented by the equation $z = f(x, y)$ is cut by two planes perpendicular to the axis of x , the first passing through the given point P corresponding to the abscissa x_0 , the second passing through the variable point p corresponding to the abscissa x . Let the same surface be also cut by two cylindrical surfaces, parallel to the axis of z and represented by the equations $y = \phi(x)$ and $y = \phi_1(x)$. We shall have four curves of intersection, and the area contained between these four curves will vary with the value of x and the position of the corresponding plane. Thus this area will be a function of x , which we shall designate by $\psi(x)$. If Δx be a very small increment of x , the expression $\Delta \psi(x)$ will represent a small surface, the projection of which on the plane of x, y will be contained between two small arcs $p q, r s$, measured on the curves represented by the equations $y = \phi(x)$ and $y = \phi_1(x)$, and between two planes perpendicular to the axis of x , corresponding to the abscissæ x and $x + \Delta x$. This understood, let θ and Θ be two numbers positive and less than unity. We shall find by a process of reasoning similar to that used in (393.) that, among the numerical values of the product $\Delta x (\phi_1(x + \Theta \Delta x) - \phi(x + \theta \Delta x))$ which correspond to the various values of the numbers θ and Θ , the least and greatest represent the surfaces of the inscribed and circumscribed rectangular parallelograms to the projection of the surface $\Delta \psi(x)$, and consequently, the projections of two new surfaces, measured on the surface represented by the equation $z = f(x, y)$. Each of these new surfaces, being included between four planes perpendicular to the axis of x , or the axis of y , and corresponding to abscissæ $x, x + \Delta x$, and to ordinates of the form $\phi(x + \theta \Delta x)$,

$\phi_1(x + \Theta \Delta x)$, will be represented by $\Delta x \int_{\phi(x + \theta \Delta x)}^{\phi_1(x + \Theta \Delta x)} \frac{1}{\cos \tau + i_1} dy$, if we suppose the difference $\phi_1(x) - \phi(x)$

positive. Hence the limit of the ratio $\frac{\Delta \psi(x)}{\Delta x}$, or $\frac{d \psi(x)}{dx} = \int_{\phi(x)}^{\phi_1(x)} \sec \tau dy$. And lastly, as we have obviously

$\psi(x_0) = 0$, we shall have $\psi x = \int_{x_0}^x \int_{\phi(x)}^{\phi_1(x)} \sec \tau dy dx$, and for a particular value x_1 of the abscissa x ,

$A = \int_{x_0}^{x_1} \int_{\phi(x)}^{\phi_1(x)} \sec \tau dy dx$, A being the portion of the curve surface represented by the equation $z = f(x, y)$

limited by two planes perpendicular to the axis of x , the equations of which are $x = x_0$ and $x = x_1$, and by two cylindrical surfaces perpendicular to the plane of x, y , the equations of which are $y = \phi(x)$ and $y = \phi_1(x)$. It is necessary here to observe, that in this last formula, representing the value of A , the order of integration cannot be inverted.

If the bases of the cylindrical surfaces, situated in the plane of x, y , and represented by the equations $y = \phi(x)$ and $y = \phi_1(x)$ meet in two points, and if x_0 and x_1 be the abscissæ of these points, the value A , given by the preceding formula, will represent the surface, the projection of which, on the plane of the x, y , is the area contained between the bases of the two cylindrical surfaces. It would still be the same thing if the two curves $y = \phi(x)$ and $y = \phi_1(x)$ touch each other in two points having for abscissæ x_0 and x_1 . Lastly, $\phi(x)$ and $\phi_1(x)$ might be two values of y derived from the same equation, $\phi(x, y) = 0$ representing a curve limited on all sides, it would then be sufficient to substitute for x_0 and x_1 the least and greatest value of the abscissæ, which correspond to the different points of this curve, in order that the preceding value of A should represent the area, measured on the surface $z = f(x, y)$, and limited by the cylindrical surface represented by the equation $\phi(x, y) = 0$.

(396.) If for the surface $z = f(x, y)$ we substitute a surface limited on all sides, and which cannot be met in more than two points by a parallel to the axis of z , then to derive from the preceding value of A the whole area of this new surface, it will be sufficient to suppose that the cylindrical surface $\phi(x, y) = 0$ of the last paragraph, coincides with the cylindrical surface generated by a line parallel to the axis of z , and tangent, in every position, to the surface $z = f(x, y)$ and to divide the required area in two parts, separated by the curve of contact of the cylindrical surface and of the surface represented by the equation $z = f(x, y)$. In most cases this curve of contact is no other than that formed by the points for which the tangent plane is parallel to the axis of z ; and, consequently, the cylindrical surface abovementioned will be represented by the equation $\cos \tau = 0$, or

2 c 2

$\frac{1}{\sqrt{1+p^2+q^2}} = 0$. The contrary, however, might take place, if the sections made in the surface, represented by the equation $z = f(x, y)$ presented cusps. In the hypothesis we have made, the equation of the surface $z = f(x, y)$ will give for each value of x , two positive values of $\sec \tau$, which ought to be substituted one after the other in the preceding value of A , in order to obtain the two areas, the sum of which will be equal to the required area.

(397.) It is essential to remark, that the formula $A = \int_{x_0}^{x_1} \int_{\phi(x)}^{\phi_1(x)} \sec \tau \, dy \, dx$ may still be employed in the case where the functions $\phi(x)$, $\phi_1(x)$ would change their forms with the value of x so as to represent not the ordinate of one curve, but the ordinates of several curves or straight lines placed one after the other. Thus this formula might be used to find the area, measured on the surface $z = f(x, y)$ and limited by a prism having for its basis a polygon drawn in the plane of x, y , and its lateral edge parallel to the axis of z .

(398.) If the projection of the area A , on the plane of x, y , was composed of several parts so disposed that the linear section made in this surface by a plane perpendicular to the axis of x , and corresponding to the abscissa x , were composed of several lengths, the first contained between two given lines, the second between two other lines, &c., then to find the value of the area A , it would be sufficient to divide it in several parts. Let us suppose that $y_0, y_1; y_2, y_3$ are the functions of x , which represent, between the limits x_0 and x_1 , the ordinates which contain between them the parts of the area. We shall divide the area A , in as many corresponding parts, which will be measured by the integrals

$$\int_{x_0}^{x_1} \int_{y_0}^{y_1} \sec \tau \, dy \, dx, \int_{x_0}^{x_1} \int_{y_2}^{y_3} \sec \tau \, dy \, dx, \&c.$$

and by adding all these integrals we shall have the value of A ,

$$\begin{aligned} A &= \int_{x_0}^{x_1} \int_{y_0}^{y_1} \sec \tau \, dy \, dx + \int_{x_0}^{x_1} \int_{y_2}^{y_3} \sec \tau \, dy \, dx + \&c. \dots \\ &= \int_{x_0}^{x_1} \left\{ \int_{y_0}^{y_1} \sec \tau \, dy \, dx + \int_{y_2}^{y_3} \sec \tau \, dy \, dx + \&c. \dots \right\}. \end{aligned}$$

In the same hypothesis the projection of the area A will be represented by

$$\int_{x_0}^{x_1} \left\{ \int_{y_0}^{y_1} dy + \int_{y_2}^{y_3} dy + \&c. \dots \right\} dx = \int_{x_0}^{x_1} (y_1 - y_0 + y_3 - y_2 + \dots) dx.$$

The formulæ given for the value of A , in the different cases we have examined, would be inexact, if the surface were met in several points by lines parallel to the axis of z . Then it would be necessary to divide the required area in several parts, by means analogous to those we have made use of in the case of a plane area limited by curves.

(399.) We shall now apply those general formulæ to some particular cases. First it may be remarked, that $\int_{y_0}^{y_1} \sec \tau \, dy = (y_1 - y_0) \sec t$, t being a mean value between the various values of τ , corresponding to the various

values of y between the limits y_1 and y_0 . Hence $A = \int_{x_0}^{x_1} (y_1 - y_0) \sec t \, dx = \sec t_1 \int_{x_0}^{x_1} (y_1 - y_0) \, dx$, t_1 being a mean value between the various values of t which correspond to the values of x , between the limits x_1 and x_0 , that is to say, t_1 being a mean value between the acute angles which the plane of x, y forms with the tangent planes at the different points of the surface A . Moreover, since as any plane may be taken for the plane of x, y , the truth of the following proposition becomes obvious. The ratio between a curve surface and its projection upon any plane, is a mean quantity between the values of the secants of the acute angles which the tangent planes at the different points of the surface make with the same plane. Hence, if the angle of the tangent plane with the plane of x, y is the same at every point of the surface, the area measured on this surface is equal to the product of its projection on the plane of x, y by the secant of the angle which the tangent plane makes with the plane of x, y . According to this last proposition, the area of the frustum of a cone is equal to the projection of the surface on the base, which projection is equal to the difference of the two bases, multiplied by the secant of the angle which the side of the frustum makes with the base. And it is easy to verify that this expression of the surface of a frustum of a cone agrees with that given in Geometry.

When the equation of the surface is of the form $z = f(x)$, that is to say, when the surface is a cylindrical surface parallel to the axis of y , we have $\sec \tau = \sqrt{1 + (f'(x))^2}$, and $\sec \tau$ containing only x , the integration relative to y gives immediately $A = \int_{x_0}^{x_1} (y_1 - y_0) \sec \tau \, dx$. By means of this formula, it is easy to find the area measured on a cylindrical surface, parallel to the axis of y , and contained between two straight lines parallel to the axis of y , and two planes perpendicular to it. Then y_1 and y_0 are two constant quantities, and we have $A = (y_1 - y_0) \int_{x_0}^{x_1} \sec \tau \, dx$, $y_1 - y_0$ being the distance between the two planes. Moreover, it is obvious that τ is equal to the angle which the tangent to the base of the cylinder, on the plane of xz , makes with the axis of x ,

Integral
Calculus.

hence $\int_{x_0}^{x_1} \sec \tau dx$ represents the length of the arc measured on this curve, and having for its extremities the two

points corresponding to the abscissæ x_1 and x_0 . Therefore the area measured on the surface of a cylinder, parallel to the axis of y , between two planes parallel to the same line, and two planes perpendicular to it, is equal to the distance of these two planes, multiplied by the length of the arc of the base of the cylinder, contained between the planes parallel to the axis of y .

Let us next consider the surface of the cylinder represented by the equation $x^2 - rx + z^2 = 0$, and let it be proposed to find the portion of this surface limited by the surface of the sphere having the origin for its centre and for radius r . The equation of the sphere is therefore $x^2 + y^2 + z^2 = r^2$, and the curve of intersection of the sphere and cylinder has for projection on the plane of x, y the parabola represented by the equation $y^2 = r(r - x)$, which gives for y the two values $y = -\sqrt{r(r - x)}$, $y = \sqrt{r(r - x)}$. Hence the area measured on the cylindrical surface on the positive side of the axis of z , and limited by the curve of intersection of the

cylinder with the sphere, is equal to $\int_0^r 2 \sqrt{r(r - x)} \sec \tau dx$, τ being the angle made by the tangent plane to the cylindrical surface, at the point corresponding to the abscissa x , with the plane of x, y . If we take $z = +\sqrt{r(r - x)}$, we shall have

$$\sec \tau = \sqrt{1 + \frac{(\frac{1}{2}r - x)^2}{rx - x^2}} = \frac{\frac{1}{2}r}{\sqrt{rx - x^2}},$$

and, consequently,

$$\int_0^r 2 \sqrt{r(r - x)} \sec \tau dx = r^{\frac{3}{2}} \int_0^r \frac{dx}{\sqrt{x}} = 2r^2;$$

therefore A , or the whole surface limited by the sphere, not only on the positive side of z , but also on the negative side, is equal to $4r^2$.

If it were required to find the area of the portion of the surface of the sphere, limited by the surface of the cylinder, on the positive side of y and z , we should make use of the formula of (397.), and assume $x_0 = 0$, $x_1 = r$, $y_0 = \sqrt{r^2 - rx}$, $y_1 = \sqrt{r^2 - x^2}$. Moreover, the equation of the sphere being differentiated successively with respect to x and y , gives

$$x + z \frac{dz}{dx} = 0, \quad y + z \frac{dz}{dy} = 0, \quad \text{and } p = -\frac{x}{z}, \quad q = -\frac{y}{z}, \quad \text{therefore } \sec \tau = \frac{r}{z} = \frac{r}{\sqrt{r^2 - x^2 - y^2}}.$$

This understood, we shall have

$$A = r \int_0^r \int_{\sqrt{r^2 - rx}}^{\sqrt{r^2 - x^2}} \frac{1}{\sqrt{r^2 - x^2 - y^2}} dy dx.$$

We have, generally,

$$\int \frac{dy}{\sqrt{r^2 - x^2 - y^2}} = \sin^{-1} \frac{y}{\sqrt{r^2 - x^2}} + c,$$

c being a quantity independent of y , and, consequently,

$$\int_{\sqrt{r^2 - rx}}^{\sqrt{r^2 - x^2}} \frac{dy}{\sqrt{r^2 - x^2 - y^2}} = \frac{\pi}{2} - \sin^{-1} \sqrt{\frac{r}{r+x}} = \cos^{-1} \sqrt{\frac{r}{r+x}}.$$

Therefore

$$A = \int_0^r \cos^{-1} \left(\sqrt{\frac{r}{r+x}} \right) dx.$$

To find this integral let $s \cos^{-1} \left(\sqrt{\frac{r}{r+x}} \right)^{\frac{1}{2}}$, we shall have $x = r \tan^2 s$, and

$$\int \cos^{-1} \left(\sqrt{\frac{r}{r+x}} \right)^{\frac{1}{2}} dx = \int s dx = sx - \int x ds = sx - r \int \left(\frac{1}{\cos^2 s} - 1 \right) ds = (x + r)s - r \tan s + \text{const},$$

and, finally,

$$\int_0^r \cos^{-1} \left(\sqrt{\frac{r}{r+x}} \right)^{\frac{1}{2}} dx = \left(\frac{\pi}{2} - 1 \right) r^2.$$

This quantity being doubled will give the portion of the surface of the sphere limited by the cylinder on the positive side of the axis of y , and corresponding to both positive and negative values of z . The area of this portion of surface is therefore $(\pi - 2)r^2 = (1.41 \dots) r^2$.

(400.) Let $y = f(x)$ be the equation of a curve drawn in the plane of (x, y) ; and let us suppose that this curve turns round the axis of x , it will generate a surface of revolution represented by the equation $y^2 + z^2 = \{f(x)\}^2$. The portion of this surface, situated on the positive side of the axis of y , between two planes perpendicular to the

axis of x , will be represented by the formula $\int_{x_0}^{x_1} \int_{-f(x)}^{f(x)} \sec \tau dx$, x_1 and x_0 being the abscissæ corresponding to the two given planes, and $f(x)$ being supposed not to change its sign between the limits x_0 and x_1 . As to the

Integral
Calculus.

value of $\sec \tau$, it is easy to find $\sec \tau = \pm \frac{f(x) \sqrt{1 + (f'(x))^2}}{\sqrt{(f(x))^2 - y^2}}$. Moreover, it is easy to see that

$$\int_{-f(x)}^{f(x)} \frac{dy}{\sqrt{(f(x))^2 - y^2}} = \pi,$$

and also that $f(x) \sqrt{1 + (f'(x))^2}$ is precisely the length of the normal of the generating curve of the surface of revolution, corresponding to the abscissa x . Consequently, the integral may be reduced to $\pi \int_{x_0}^{x_1} N dx$. The

double of this formula will be the whole area, measured on the surface of revolution, and contained between two planes perpendicular to the axis of x corresponding to the abscissæ x_0 and x_1 .

This formula being demonstrated for the case in which $f(x)$ does not change sign between the limits x_0 and x_1 , it is sufficient to make use of it in the contrary case, to divide the area A into several parts corresponding to the different portions of the curve situated on different sides of the axis of x .

It is also easy to see, that a portion of the surface A contained between two planes passing through the axis of x , and inclined to each other at an angle ϕ , will be equal to $\phi \int_{x_0}^{x_1} N dx$. Lastly, if $f(x)$ does not change sign between the limits x_0 and x_1 , this last formula and the preceding, or value of A , may be replaced by either of the following expressions

$$\phi \int_{x_0}^{x_1} y \sec \tau dx = \phi \int_{x_0}^{x_1} y \sqrt{1 + y'^2} dx, \text{ and } 2\pi \int_{x_0}^{x_1} y \sec \tau dx = 2\pi \int_{x_0}^{x_1} y \sqrt{1 + y'^2} dx.$$

(401.) We may now apply these general formulæ to a few examples.

Let the generating curve $y = f(x)$ be a straight line parallel to the axis of x , and situated at a distance r from that axis. Then $N = r$, and $A = 2\pi \int_{x_0}^{x_1} r dx = 2\pi r (x_1 - x_0)$, which is the well-known expression of the

lateral surface of the cylinder generated by a parallel to the axis of x , turning round that axis, and limited by two planes perpendicular to the axis of x , and situated at distances x_0 and x_1 from the origin.

Let the generating curve be the circumference having for its radius r , and its centre on the axis of x , then A will represent the surface of a spherical zone, of the sphere generated, having for its height $x_1 - x_0$. In that case, we have still $N = r$, and consequently, $A = 2\pi r (x_1 - x_0)$. Hence the surface of a spherical zone is equal to its altitude multiplied by the circumference of a great circle of the sphere. If the altitude is equal to the diameter of the sphere, the spherical zone becomes the whole area of the sphere, which therefore is equal to four great circles.

Let the generating curve be the ellipse represented by the equation $\frac{x^2}{a^2} + \frac{y^2}{b^2} = 1$. The equation of the surface generated will be $\frac{x^2}{a^2} + \frac{y^2 + z^2}{b^2} = 1$, and we shall have $N = \frac{b}{a} \sqrt{a^2 - \left(1 + \frac{b^2}{a^2}\right) x^2}$. If we suppose $a > b$, we shall have, in designating by e , the eccentricity of the ellipse, $ae = \sqrt{a^2 - b^2}$, and consequently,

$$N = \frac{b}{a} \sqrt{a^2 - e^2 x^2}, \text{ and } A = 2\pi \frac{b}{a} \int_{x_0}^{x_1} \sqrt{\left(\frac{a^2}{e^2} - x^2\right)} dx.$$

But $\frac{2b}{a} \int_{x_0}^{x_1} \sqrt{\left(\frac{a^2}{e^2} - x^2\right)} dx$ is the area of a portion of the ellipse represented by the equation

$\frac{e^2 x^2}{a^2} + \frac{y^2}{b^2} = 1$, limited by the two ordinates corresponding to the abscissæ x_0 and x_1 . Hence, if an ellipse is

supposed to turn round its transverse or greater axis, the surface generated by the revolution of an arc of this ellipse will be equal to the product of the number π by the surface limited by the two planes which contain the bases of the zone, in a second ellipse, which may be derived from the first, in increasing the transverse or greater axis in the inverse ratio of the eccentricity.

When the altitude of the zone becomes equal to the transverse axis of the generating ellipse, the preceding theorem gives the value of the area of the whole ellipsoid, and this may be put under the following form,

$$2\pi b^2 + 2\pi \frac{ab}{e} \tan^{-1} \frac{ae}{b}.$$

If we suppose $a < b$, we shall have by designating still by e the eccentricity of the ellipse, $be = \sqrt{b^2 - a^2}$, and

$$N = \frac{b^2 e}{a} \sqrt{\left(\frac{a^4}{b^2 e^2} + x^2\right)}, \text{ and hence } A = 2\pi \frac{b^2 e}{a^3} \int_{x_0}^{x_1} \sqrt{\left(\frac{a^4}{b^2 e^2} + x^2\right)} dx;$$

but $\frac{2b^2 e}{a^3} \int_{x_0}^{x_1} \sqrt{\left(\frac{a^4}{b^2 e^2} + x^2\right)} dx$ is obviously the area limited by the ordinates corresponding to the abscissæ

Integral
Calculus.

Part III.

z_0 and x_1 , in the hyperbola represented by the equation $\frac{y^2}{b^2} - \frac{e^2 x^2}{a^2} = 1$. Hence if an ellipse is made to turn

round its smaller axis, the surface of the zone generated by the revolution of an arc of this ellipse is equal to the product of the number π by the surface limited by the two planes containing the bases of the zone, in an hyperbola the transverse axis of which coincides with the smaller axis of the ellipse, and the other is equal to the square of the greater axis of the ellipse divided by the square of the smaller axis and the eccentricity.

When the altitude of the zone coincides with the smaller axis $2a$ of the generating ellipse, the preceding theorem gives the area of the whole ellipsoid, and the value may be put under the following form:

$$2\pi b^2 + \frac{\pi a^2}{e} \log \left(\frac{1+e}{1-e} \right).$$

Let the generating curve be the hyperbola represented by one of the equations $\frac{x^2}{a^2} - \frac{y^2}{b^2} = 1$, $\frac{y^2}{b^2} - \frac{x^2}{a^2} = 1$.

Then the equation of the surface of revolution will be one of the two $\frac{x^2}{a^2} - \frac{y^2 + z^2}{b^2} = 1$, $\frac{y^2 + z^2}{b^2} - \frac{x^2}{a^2} = 1$, and

we shall have $N = \frac{b}{a} \sqrt{\left(1 + \frac{b^2}{a^2}\right)x^2 \mp a^2}$, or if we make $ae = \sqrt{a^2 + b^2}$, $N = \frac{b}{a} \sqrt{e^2 x^2 \mp a^2}$. Therefore

we shall have $A = 2\pi \frac{b}{a} \int_{x_0}^{x_1} \left(x^2 \mp \frac{a^2}{e^2}\right) dx$. But it is obvious that $\frac{2b}{a} \int_{x_0}^{x_1} \left(x^2 \mp \frac{a^2}{e^2}\right) dx$ is the area limited

by the two ordinates corresponding to the abscissæ x_0 and x_1 , in one of the hyperbolas represented by the equations $\frac{e^2 x^2}{a^2} - \frac{y^2}{b^2} = 1$, $\frac{y^2}{b^2} - \frac{e^2 x^2}{a^2} = 1$. Hence, if an hyperbola represented by the equation $\frac{x^2}{a^2} - \frac{y^2}{b^2} = 1$,

turns round its real axis, the surface of the zone generated by an arc of this hyperbola is equal to the product of π by the surface limited by the two planes which contain the bases of the zone in a second hyperbola which may be derived from the first, in decreasing the length of the transverse axis of the generating hyperbola, in the inverse ratio of the eccentricity.

Let us next suppose the generating curve to be the parabola represented by the equation $y^2 = 2px$, p being a positive quantity. The equation of the surface generated by the revolution of this parabola round the axis of x

will be $y^2 + z^2 = 2px$, and we shall have $N = \sqrt{2px + p^2}$. Hence $x = N^2 - \frac{p^2}{2}$, $dx = N dN$, and the

value of A will be $\frac{2\pi}{p} \int_{n_0}^{n_1} N^3 dN = \frac{2\pi}{3p} (n_1^3 - n_0^3)$, n_1 and n_0 being the values of the normals at the points, the

abscissæ of which are x_0 and x_1 . If we suppose $x_0 = 0$, then $n_0 = p$, and $A = \frac{2\pi}{3} \left(\frac{n_1^3}{p} - p^2 \right)$.

Let the curve be the hyperbola represented by the equation $xy = \frac{r^2}{2}$. The equation of the surface generated by the revolution of this curve round the axis of x is $x^2(y^2 + z^2) = \frac{1}{4}r^4$, and we shall have

$$A = \pi r^2 \int_{x_0}^{x_1} \sec \tau \frac{dx}{x}. \quad \text{But } \tan \tau = \frac{1}{2} \frac{r^2}{x^2}, \text{ and } x^2 = \frac{r^2}{2 \tan \tau}.$$

Hence

$$lx = l(r) - \frac{1}{2} l(2) - \frac{1}{2} l \tan \tau, \quad \text{or } \frac{dx}{x} = -\frac{1}{2} \frac{d\tau}{\sin \tau \cos \tau}.$$

Consequently, if we call τ_1 and τ_0 , the values of τ corresponding to $x = x_1$ and $x = x_0$, we shall have

$$A = -\frac{1}{2} \pi r^2 \int_{\tau_0}^{\tau_1} \frac{d\tau}{\sin \tau \cos^3 \tau} = \frac{1}{2} \pi r^2 \left\{ \frac{1}{\cos \tau_0} - \frac{1}{\cos \tau_1} + l \tan \frac{\tau_0}{2} - l \tan \frac{\tau_1}{2} \right\}.$$

Let us suppose that the generating curve is the logarithmic represented by the equation $y = e^{\frac{x}{a}}$. We shall have

$$A = 2\pi \int_{x_0}^{x_1} e^{\frac{x}{a}} \sqrt{1 + y'^2} dx, \quad \text{but } y' = \frac{\tau}{a} e^{\frac{x}{a}}, \text{ and } dy' = \frac{A}{a^2} e^{\frac{x}{a}} dx,$$

hence

$$A = 2\pi a^2 \int_{y'_0}^{y'_1} \sqrt{1 + y'^2} dy',$$

y'_1 and y'_0 being the values of y' corresponding to $x = x_1$ and $x = x_0$. Moreover, we have

$$\int \sqrt{1 + y'^2} dy' = \frac{1}{2} y' \sqrt{1 + y'^2} + \frac{1}{4} l \left\{ \frac{\sqrt{1 + y'^2} + y'}{\sqrt{1 + y'^2} - y'} \right\} + \text{const} = \frac{1}{2} \frac{\sin \tau}{\cos^3 \tau} + \frac{1}{2} l \left(\frac{1 + \sin \tau}{1 - \sin \tau} \right) + \text{const}.$$

and we shall have

$$A = \pi a^2 \left\{ \frac{\sin \tau_1}{\cos^2 \tau_1} + l \tan \left(\frac{\pi}{4} + \frac{\tau}{2} \right) - \frac{\sin \tau_0}{\cos^2 \tau_0} - l \tan \left(\frac{\pi}{4} + \frac{\tau_0}{2} \right) \right\}.$$

Let again the curve be the catenary represented by the equation $y = a \frac{e^{\frac{x}{a}} + e^{-\frac{x}{a}}}{2}$. Then $N = \frac{a}{4} (e^{\frac{x}{a}} + e^{-\frac{x}{a}})^2$, and we have, in supposing $x_0 = 0$,

$$A = \pi a \int_{x_0}^{x_1} \left(1 + \frac{e^{2x/a} + e^{-2x/a}}{2} \right) dx, \text{ or } A = \pi a \left\{ x_1 + \frac{a}{4} (e^{\frac{2x_1}{a}} + e^{-\frac{2x_1}{a}}) \right\}.$$

For the last example, we shall suppose that the generating curve is the cycloid represented by the equations $x = r(w - \sin w)$, $y = r(1 - \cos w)$. Then we shall have

$$\sqrt{(1 + y'^2)} dx = \sqrt{(dx^2 + dy^2)} = 2^{\frac{1}{2}} \cdot r(1 - \cos w)^{\frac{1}{2}} dw,$$

and, consequently,

$$A = 2^{\frac{3}{2}} \pi r^2 \int_{w_0}^{w_1} (1 - \cos w)^{\frac{3}{2}} dw = 8 \pi r^2 \int_{w_0}^{w_1} \sin^3 \frac{w}{2} dw. \text{ But } 8 \sin^3 \frac{w}{2} = \left(\frac{e^{\frac{w}{2}} \sqrt{-1} - e^{-\frac{w}{2}} \sqrt{-1}}{\sqrt{1}} \right)^3 = 6 \sin \frac{w}{2} - \sin \frac{3w}{2}.$$

Hence, if we assume $w_0 = 0$, we shall have

$$A = 4 \pi r^2 \left\{ \frac{8}{3} - 3 \cos \frac{w_1}{2} + \frac{1}{3} \cos \frac{3w_1}{2} \right\}.$$

If we wish, in particular, to have the area described by a branch of hyperbola, we must suppose $w_1 = 2\pi$, and then we find $A = \frac{64}{3} \pi r^2 = \frac{\pi}{3} (8r)^2$.

(402.) We shall conclude what we proposed to say with respect to the evaluation of curve surfaces of revolution with two theorems which may be useful.

Let us suppose that the curve which is made to turn round the axis of x is represented by the equation $y = b + f(x)$, b designating a constant and positive quantity. The normal to this curve will be equal to $\{b + f(x)\} \sqrt{1 + (f'(x))^2}$, and we shall have for the area generated by the arc, the extremities of which have for abscissæ x_1 and x_0 ,

$$B = 2\pi \int_{x_0}^{x_1} f(x) \{1 + (f'(x))^2\} dx + 2\pi b \int_{x_0}^{x_1} \sqrt{1 + (f'(x))^2} dx = A + 2\pi b \int_{x_0}^{x_1} \sqrt{1 + (f'(x))^2} dx,$$

A being as before the area generated by the curve represented by the equation $y = f(x)$, revolving round the axis of x . But if s represent the length of the arc of the generating curve,

$$s = \int_{x_0}^{x_1} \sqrt{1 + (f'(x))^2} dx. \text{ Hence } B = A + 2\pi b s.$$

Therefore, if successively an arc of a curve is made to revolve, 1. round an axis arbitrarily chosen, 2. round an axis parallel to the first, and at a distance b from it, the difference between the areas of the two surfaces of revolution generated in the two hypotheses, will be the product of the generating arc by the circumference which a point of the second axis would describe if it turned round the first, provided, however, that the two axes should not meet the generating arc, and should be situated on the same side with respect to this arc.

If for the constant b the constant $-b$ be substituted, and if, moreover, we suppose $fx < b$ for every value of x between the limits x_0 and x_1 , the above formula will become $A - 2\pi b s$, and will represent the area B taken with the sign $-$. Thus we shall have $A + B = 2\pi b s$. Hence, if, in the above supposition the two axes of revolution are situated, with respect to the generating arc, the first on one side, and the other on the other side, the sum of the surfaces generated will be equal to the product of the generating arc, by the circumference which one point of the second axis will describe in turning round the other.

By means of these theorems, which may easily be extended to the case where the generating arc should meet in several points planes perpendicular to the axis of rotation, it will be easy to determine the area of the zone generated by an arc of a circle, represented by s , turning round an axis. Let r be the radius of this arc, b the distance of the centre to the axis, and h the altitude of the zone. Let us imagine that a second axis, drawn through the centre, in a direction parallel to the first, does not meet the arc s . If we call A the surface of the zone generated by the circular arc, revolving round the second axis, we shall have $A = 2\pi r h$, and, consequently, $B = 2\pi (bs + rh)$, or $B = 2\pi (bs - rh)$. If the generating arc is equal to half a circumference, then $h = 2r$, $s = \pi r$, and $B = 2\pi r (\pi b + 2r)$, or $B = 2\pi r (\pi b - 2r)$. These two values added will give the area of the surface, designated by the name of *annular surface*, and which therefore is equal to $4\pi^2 b r$.

In the same manner it may be proved that any curve having a centre, and revolving round an axis which does not meet it, generates a surface which has for its measure the product of its perimeter by the circumference which the centre describes round that axis.

Integral
Calculus.

Part III.

(403.) We shall now proceed to explain the process by which the volume or bulk limited by any given surface or surfaces may be determined. This process is called *cubature*. To arrive more easily at a general solution of the problem of the cubature of bodies, we shall first examine the case where it is required to find the volume of a cylinder, the generating line of which is perpendicular to the base, and which, for that reason, may be called a *right cylinder*.

It is easy to prove that the volume V of such a cylinder, the base of which is represented by U and the altitude by h , is equal to the product of the base by the altitude or to hU .

Let us suppose that all the points of space are referred to three rectangular axes; and let the cylinder be placed in such a manner as to have its generating line parallel to the axis of z , and its base on the plane of x, y . At a distance x from the plane of z, y , let us conceive a plane perpendicular to the axis of x ; the intersection of this plane with the base of the cylinder will be a straight line, the length of which will easily be derived from the equation of the circumference of the base of the cylinder, and will be a certain function of x ; let it be represented by $f(x)$. Let also v be that part of the volume V which is situated with respect to the same plane, on the negative side of the x , and u be the corresponding part of the base U of the cylinder. If x become $x + \Delta x$, Δx being an infinitely small quantity, the volume v will become $v + \Delta v$, and the base u of the volume v , $u + \Delta u$. Now, it is easy to see, 1. that the base Δu of the volume Δv is contained between two rectangular parallelograms the surfaces of which may be represented by the products $(f(x) + i_1) \Delta x$, and $(f(x) + i_2) \Delta x$, i_1 and i_2 designating two infinitely small quantities; 2. that the volume Δv is contained between two rectangular parallelipipeds having the same altitude as the cylinder, and for their bases the two preceding rectangular parallelograms. Hence we shall have $\Delta v = h(f(x) + i) \Delta x$, i being an infinitely small quantity, the value of which is between those of i_1 and i_2 . If we divide both sides of this equation by Δx , we shall have $\frac{\Delta v}{\Delta x} = h(f(x) + i)$, and consequently, if we take the limits of both sides $\frac{dv}{dx} = hf(x)$, or $dv = hf(x) dx$.

This understood, let x_0 and x_1 be the least and the greatest value of x which correspond to the base U , we shall have $v = h \int_{x_0}^x f(x) dx$, and $V = h \int_{x_0}^{x_1} f(x) dx$, but the definite integrals contained in these expressions represent respectively the surfaces u and U , therefore $v = hu$, and $V = hU$.

The preceding demonstration would not apply, if the line, the length of which has been represented by $f(x)$, was composed of several separate lengths $f_1(x)$, $f_2(x)$, $f_3(x)$, &c. contained, the first between two given lines, the second between two other given lines, &c. But then we might easily divide the volume V into several parts, V_1 , V_2 , &c. . . . , and the base U into corresponding parts, U_1 , U_2 , U_3 , &c. . . . , so as to establish by the preceding reasoning the following equations, $V_1 = hU_1$, $V_2 = hU_2$, $V_3 = hU_3$, &c. . . . , and the addition of these would lead to the formula $V = hU$.

Let us suppose now, that the volume V to be determined, is limited by any surface whatever. Let $F(x)$ be the area of the section made in the volume V by a plane perpendicular to the axis of x , and corresponding to the abscissa x , and let again the portion of V , situated with respect to that plane on the negative side of abscissæ, be represented by v . If we consider a second plane perpendicular to the axis of x and corresponding to the abscissa $x + \Delta x$, supposing as before Δx to be an infinitely small quantity, the area of the section corresponding to this new plane may be represented by $F(x) + \Delta F(x)$, and the corresponding volume by $v + \Delta v$. It is obvious that the volume Δv will be contained between two cylinders, the volumes of which may be represented by $(F(x) + i_1) \Delta x$, $(F(x) + i_2) \Delta x$, i_1 and i_2 being two infinitely small quantities; hence we shall have $\Delta v = \{F(x) + i\} \Delta x$, i being also an infinitely small quantity, having a mean value between those of i_1 and i_2 . Therefore, if, after having divided both sides of the last equation by Δx , we take the limits, we shall have $\frac{dv}{dx} = F(x)$, or, which is the same thing, $dv = F(x) dx$. Hence, if we call x_0 and x_1 the least and greatest

value of x corresponding to the points of the volume v , that is to say, the limits between which the value of x ought to remain, in order that a plane perpendicular to the axis of x , and corresponding to that abscissa, should

meet the volume V , we shall have $v = \int_{x_0}^x F(x) dx$, and $V = \int_{x_0}^{x_1} F(x) dx$.

The last formula holds good in the case where the area $F(x)$ of the section made in the volume V by a plane perpendicular to the axis of x is changed into the sum of several surfaces,

$$F_1(x), \quad F_2(x), \quad F_3(x), \quad \&c. \quad \dots$$

Then the volume V is the sum of several volumes represented by the integrals

$$\int_{x_0}^{x_1} F_1(x) dx, \quad \int_{x_0}^{x_1} F_2(x) dx, \quad \int_{x_0}^{x_1} F_3(x) dx, \quad \&c. \dots$$

in each of which the function under the sign $\int$ has constantly a positive value, or is equal to nothing, whilst the abscissa x varies between the limits x_0 and x_1 . This understood, we shall have, at the same time, in the present case,

$$F(x) = F_1(x) + F_2(x) + F_3(x) + \&c. \dots \quad N = \int_{x_0}^{x_1} F_1(x) dx + \int_{x_0}^{x_1} F_2(x) dx + \int_{x_0}^{x_1} F_3(x) dx + \&c. \dots$$

or

$$V = \int_{x_0}^{x_1} F(x) dx.$$

Let us suppose, for instance, that x_0 and x_1 being two constant quantities, y_0 and y_1 two functions of the

Integral Calculus. variable x , and z_0, z_1 two functions of the variables x, y , it is required to find the volume contained between the two curve surfaces represented by the equations $z = z_0, z = z_1$, between the two cylindrical surfaces represented by the two equations $y = y_0, y = y_1$, and finally between the two planes $x = x_0, x = x_1$. Part III.

The section made in this volume by a plane parallel to the plane of y, z , and corresponding to a particular value of the abscissa x , will be the area contained between four lines, namely, two curves, and two lines parallel to the axis of z . Let us add, that in order to obtain the equations of these four lines, it will be sufficient to consider x as a constant quantity in the equations $z = z_0, z = z_1, y = y_0, y = y_1$. Let $F(x)$ represent the area of this section, and $f(x, y)$ the length of the linear section made in the surface $F(x)$ by a plane perpendicular to the axis of y , and corresponding to a particular value of y . We shall obviously have $f(x, y) = z_1 - z_0$, and hence

$$F(x) = \int_{y_0}^{y_1} f(x, y) dy,$$

or which is the same thing,

$$F(x) = \int_{y_0}^{y_1} (z_1 - z_0) dy = \int_{y_0}^{y_1} \int_{z_0}^{z_1} dz dy$$

Consequently, since

$$V = \int_{x_0}^{x_1} F(x) dx, \text{ we shall have } V = \int_{x_0}^{x_1} \int_{y_0}^{y_1} \int_{z_0}^{z_1} dz dy dx,$$

$$\text{or } V = \int_{x_0}^{x_1} \int_{y_0}^{y_1} (z_1 - z_0) dy dx, \quad \text{or } V = \int_{x_0}^{x_1} \int_{y_0}^{y_1} f(x, y) dy dx.$$

It is necessary to remark, that the function $f(x, y)$ is precisely the length of a linear section made in the volume V by means of two planes perpendicular to the axis of x and y . Moreover it is easy to verify that the preceding expressions for the volume V apply to the case in which the linear section $f(x, y)$ instead of being a single straight line would be composed of several distinct lines, the lengths of which would be

$$f_1(x, y), \quad f_2(x, y), \quad f_3(x, y), \quad \&c. \dots$$

and would be contained, the first between two given surfaces, the second between two other surfaces, &c.

The preceding formulæ might also be established by another train of reasoning. Let us suppose first that the quantities y_0, y_1 are constant, that is to say, independent of x . Then the volume V will be comprised between the surfaces represented by the equations $z = z_0, z = z_1$, and four planes perpendicular to the axis of x and y , passing through two straight lines parallel to the axis of z , the first corresponding to the point the coordinates of which are x_0 and y_0 , and the second to the point the coordinates of which are x_1 and y_1 . Now, if we substitute for this second line another parallel to the axis of z corresponding to a point the coordinates of which are generally x and y , the volume V will be changed into another volume which will be a function of x and y . Let us represent this last volume by $\phi(x, y)$, and let $\Delta x, \Delta y$ be infinitely small increments of x and y . The very small increment of V , which we may designate by $\Delta x \Delta y \phi(x, y)$, will obviously have a mean value between the volumes of two parallelepipeds, the one inscribed and the other circumscribed, that is to say, a mean value between two products of the following form,

$$[f(x, y) + i_1] \Delta x \Delta y, \quad [f(x, y) + i_2] \Delta x \Delta y,$$

i_1 and i_2 being two infinitely small quantities. We shall have, therefore,

$$\Delta_y \Delta_x \phi(x, y) = [f(x, y) + i] \Delta x \Delta y,$$

i being an infinitely small quantity having a mean value between i_1 and i_2 . If, in the last equation, we take the limits, first with respect to Δy and then with respect to Δx , we shall obtain the two following equations,

$$\frac{d \Delta_x \phi(x, y)}{dy} = [f(x, y) + i] \Delta x, \quad \frac{d^2 \phi(x, y)}{dx dy} = f(x, y);$$

and consequently integrating first with respect to y , secondly with respect to x , and observing that the function $\phi(x, y)$ vanishes not only for $x = x_0$, whatever be the value of y , but also for $x = x_0$ whatever be the value of x , we shall find

$$\phi(x, y) = \int_{x_0}^x \int_{y_0}^y f(x, y) dy dx, \quad \text{and } V = \int_{x_0}^{x_1} \int_{y_0}^{y_1} f(x, y) dy dx.$$

This formula is therefore demonstrated for the case in which y_0 and y_1 are constant quantities. To deduce from this particular case the general one, the formula $\{f(x, y) + i\} \Delta x dy$ must first be integrated between the limits y_0 and y_1 . We shall thus find

$$\Delta_x \phi(x, y) = \Delta x \int_{y_0}^{y_1} \{f(x, y) + i\} dy,$$

a formula which will give the value of the volume $\Delta x \phi(x, y)$ contained between the surfaces $z = z_0, z = z_1$, and four planes parallel two and two, namely, the two first being perpendicular to the axis of y , and distant from each other of a quantity $y_1 - y_0$, and the two others perpendicular to the axis of x , at a distance from each other equal to Δx . If, in the equations $y = y_0, y = y_1$, the quantities y_0 and y_1 are no longer supposed to represent constant quantities, but functions of x , and if $v = \psi(x)$ represent that part of the volume V cut off by a plane perpendicular to the axis of x , and situated with respect to this plane on the negative side of x , then it may be easily proved that the volume $\Delta \psi(x)$ has a mean value between those of two other volumes represented by products of the following form,

Integral
Calculus.

$$\Delta x \int_{y_0+i_0}^{y_1+i_1} \{f(x, y) + i\} dy,$$

i_0 or i_1 designating quantities which have a mean value between those of the various increments of y_0 or y_1 , when x receives various infinitely small increments between 0 and Δx . Hence the value $\frac{\Delta \psi(x)}{\Delta x}$ will be a mean between two integrals of the form above, and in each of which i_0 , i_1 and i are infinitely small quantities. Besides, if the numerical value of Δx be supposed to decrease indefinitely, these two integrals will converge towards the same limit, namely, $\int_{y_0}^{y_1} f(x, y) dy$. Therefore the limit of the ratio $\frac{\Delta \psi(x)}{\Delta x}$ or $\frac{d\psi(x)}{dx}$ will be equivalent to $\int_{y_0}^{y_1} f(x, y) dy$. Integrating now this last expression with respect to x , and observing that $\psi(x)$ ought to become equal to nothing when $x = x_0$, we shall conclude

$$\psi(x) = \int_{x_0}^x \int_{y_0}^{y_1} f(x, y) dy dx, \quad \text{and for } x = x_1, V = \int_{x_0}^{x_1} \int_{y_0}^{y_1} f(x, y) dy dx.$$

This last formula leads to the following remarks. If the cylindrical surfaces represented by the equations $y = y_0$, $y = y_1$ should intersect, and the intersection be two generating lines corresponding to the abscissæ x_0 and x_1 , the volume V would be limited on all sides by the surfaces $z = z_0$, $z = z_1$ and the two cylinders. The same remark would hold if the two cylindrical surfaces touched each other along the two generating lines corresponding to $x = x_0$ and $x = x_1$. The two cylindrical surfaces would be reduced to one, if the two functions y_0 and y_1 represented two values of y derived from the same equation between y and x . In the same hypothesis, it might happen, 1. that the surfaces represented by the equations $z = z_0$, $z = z_1$, being separate and distinct surfaces, should have for their intersection a curve situated also on the cylindrical surface; 2. that z_0 and z_1 were the two values of z derived from the same equation $f(x, y, z) = 0$, representing a surface limited on all sides, and to which the cylindrical surface would be circumscribed. In the first case, the volume V would be limited on all sides by the surfaces $z = z_0$ and $z = z_1$, in the second case V would designate the volume contained by the surface $f(x, y, z) = 0$ If $z_0 = 0$, then the volume V would be that limited in the direction of the axis of x , by the two planes $x = x_0$, $x = x_1$; in the direction of the y by the cylindrical surfaces represented by the equations $y = y_0$ and $y = y_1$; finally, in the direction of the z by the surface $z = f(x, y)$.

(404.) We shall now show some applications of the formulæ we have established.

Let us first suppose that after having drawn on a plane perpendicular to the axis of x a curve limiting an area represented by B , a straight line, not parallel to the plane of z, y , moves so as to remain constantly parallel to a given direction, and to meet, in every position, the given curve. This line will generate a cylindrical surface; and if we cut the volume V limited by this surface and the two planes represented by the equations $x = x_0$, $x = x_1$ by another plane perpendicular to the axis of x , the section will be perfectly equal to B . In this case we shall have therefore $F(x) = B$; and consequently $V = B \int_{x_0}^{x_1} dx = B(x_1 - x_0)$, or if we call h the distance of the two planes $V = Bh$. Hence the volume V of an oblique cylinder the base of which is B and the altitude h is equal to the product Bh of the base by the altitude.

(405.) Let us next consider the surface of a cone having its centre at the origin of coordinates. Let us conceive, moreover, that the base of this cone is a plan curve situated in a plane perpendicular to the axis of x , and at a distance from the origin of coordinates equal to 1. Let y_1 and z_1 be the variable coordinates of the curve, and $f(y_1, z_1) = 0$ its equation. The generating line passing through the point y_1 and z_1 of this curve will be represented by the equations $y = y_1 x$, $z = z_1 x$. Now, if y_1 and z_1 be eliminated between this equation and the equation $f(y_1, z_1) = 0$, it is clear that the resulting equation, namely, $f\left(\frac{y}{x}, \frac{z}{x}\right) = 0$, will be the equation of the surface of the cone. This understood, let A represent the area of the base of this cone. The section of this cone by a plane perpendicular to the axis of x , will be a curve similar to the base of the cone, and therefore if x be the distance of this section to the origin of coordinates, the surface of the section will be Ax^2 . We shall have, therefore, in this case $F(x) = Ax^2$, and consequently, $V = A \int_{x_0}^{x_1} x^2 dx = \frac{A(x_1^3 - x_0^3)}{3}$. If the required volume

is that limited by the surface and by the plane represented by the equation $x = x_1$, then $x_0 = 0$, and $V = \frac{1}{3} Ax_1^3$. Besides, if h be the altitude of the cone, and B the surface of the base contained in the plane $x = x_1$, then $h = x_1$ and $B = Ax_1^2$, therefore $V = \frac{1}{3} Bh$. Hence the volume limited by the surface of a cone and a plane not passing through the centre is equal to the third of the product obtained in multiplying the base by the altitude.

With respect to the truncated cone, or volume limited by the surface of the cone, and two parallel planes $x = x_0$, $x = x_1$, it has already been found equal to $\frac{1}{3}(x_1^3 - x_0^3)A$; but if b and B are the surfaces of the two bases, and h the altitude, then $b = Ax_0^2$, $B = Ax_1^2$, and $h = x_1 - x_0$, consequently, $V = \frac{1}{3}h(B + b + \sqrt{Bb})$. Hence, the volume of a truncated cone is equal to the third of the product obtained in multiplying the altitude by the sum of the two bases and a mean proportional between the two bases.

Integral
Calculus.

It is obvious that this last theorem as well as the preceding one relative to the volume of a cylinder would still hold, if the bases instead of being limited by a single continuous line was limited by a system of several lines curve or straight, and consequently, the expressions found for the volumes of cylinders and cones apply also to prisms and pyramids. Part III.

(406.) Let us next suppose, that after having drawn in the plane of x, y a curve represented by the equation $y = f(x)$, this curve is made to revolve round the axis of x , it will generate a surface of revolution, such as the section made by a plane perpendicular to the axis of x will be a circumference having for radius the ordinate of the generating curve. Therefore, if we designate by y this ordinate, the surface of the circle limited by this circumference will be πy^2 . Hence the volume V limited by the surface of revolution and two planes perpendicular to the axis of revolution $x = x_0, x = x_1$, will be $V = \pi \int_{x_0}^{x_1} y^2 dx$.

Let us apply this last formula to a few examples.

Example 1. Let the generating curve be the circle represented by the equation $x^2 + y^2 = r^2$, we shall have in supposing $x_0 = 0$,

$$V = \pi \int_0^x (r^2 - x^2) dx = \pi x \left(r^2 - \frac{1}{3} x^2 \right) = \frac{2}{3} \pi r^2 x + \frac{1}{3} \pi y^2 x,$$

hence the volume of a segment of a sphere, included between two parallel planes, one of which passes through the centre of the sphere, is equal to the volume of the cone having for its base the small base of the segment, and the same altitude, plus the surface of the spherical zone limiting the segment multiplied by one-third of the radius. If the altitude of the segment becomes equal to the radius r , the volume V will be simply reduced to $\frac{2}{3} \pi r^3$, and the double of this product $\frac{4}{3} \pi r^3$ will represent the volume of the sphere.

Example 2. Let the generating curve be the parabola represented by the equation $y^2 = 2px$, we shall find by assuming $x_0 = 0$, $v = \pi p \int_0^x 2x dx = \pi p x^2 = \frac{1}{2} \pi y^2 x$. Hence it follows that the solid generated by the revolution of the parabola produced to the point the abscissa of which is x , has for its measure half the product of its altitude by the surface of the circle πy^2 which may be considered as its base.

Example 3. Let the generating curve be that represented by the equation $y = Ax^a$, A and a being two real and constant quantities. If we suppose also $x_0 = 0$, we shall have

$$V = \pi A^2 \int_0^x x^{2a} dx = \pi A^2 \frac{x^{2a+1}}{2a+1} = \frac{1}{2a+1} \pi y^2 x.$$

If the constant a is positive, the equation $y = Ax^a$ represents a parabola of the degree a , and from the preceding formula we may therefore conclude, that the volume generated by this parabola produced from the origin to the point the abscissa of which is designated by x , is to the volume of the circumscribed cylinder as 1 to $2a+1$. In the particular case where $a = \frac{1}{2}$ we are brought back to the third example.

Example 4. If the generating curve is the logarithmic represented by the equation $y = alx$, we shall have, supposing $x_0 = 0$,

$$V = \pi a^2 \int_0^x (lx)^2 dx = \pi a^2 x \left\{ (lx)^2 - 2(lx) + 2 \right\}.$$

If the equation of the logarithmic was under the form $y = e^{\frac{x}{a}}$, then

$$V = \pi \int_0^x \frac{e^{\frac{2x}{a}}}{a^2} dx = \frac{\pi a}{2} (e^{\frac{2x}{a}} - 1) = \frac{\pi a}{2} (y^2 - 1).$$

Example 5. If the generating curve be the catenary represented by the equation $y = a \frac{e^{\frac{x}{a}} + e^{-\frac{x}{a}}}{2}$, we shall have, supposing $x_0 = 0$,

$$V = \frac{\pi a^2}{4} \int_0^x (e^{\frac{2x}{a}} + 2 + e^{-\frac{2x}{a}}) dx = \frac{\pi a^2}{2} \left\{ x + \frac{a}{4} (e^{\frac{2x}{a}} - e^{-\frac{2x}{a}}) \right\}.$$

(407.) Sometimes the determination of the volume of a body may be made easier by the substitution of another variable for the variable x . Let us suppose that the generating curve is a cycloid, the equation of which has already been given in the preceding pages. Then making use of the same letters, we shall have

$$dx = y dw, \quad y^2 dx = y^3 dw = r^3 (1 - \cos w)^3 dw,$$

and if we designate by w_0 the value of w corresponding to $x = x_0$, we shall have

$$V = \pi r^3 \int_{w_0}^w (1 - \cos w)^3 dw.$$

If we suppose $x_0 = 0$, we shall have necessarily $w_0 = 0$, and consequently,

$$V = \pi r^3 \int_0^w (1 - \cos w)^3 dw.$$

We have, besides,

Integral
Calculus.

Part III.

$$(1 - \cos w)^3 = 2^3 \sin 6 \frac{w}{2} = \frac{1}{(-2)^3} \{ e^{\frac{w}{2}} \sqrt{-1} - e^{-\frac{w}{2}} \sqrt{-1} \}^3 = \frac{1}{4} (10 - 15 \cos w + 6 \cos 2w - \cos 3w).$$

Hence we shall have

$$V = \frac{\pi r^3}{4} \left(10w - 15 \sin w + 3 \sin 2w - \frac{1}{3} \sin 3w \right).$$

In this formulæ w represents the angle described by the radius of the generating circle of the cycloid, therefore to obtain the volume generated by the first branch of the cycloid, we must, in the preceding formula, suppose $w = 2\pi$, and we shall have $V = 5\pi^2 r^3$.

(408.) If we suppose now that two curves situated in the plane of x, y and represented by the equations $y = y_0$ and $y = y_1$, the right sides of these two equations being two functions of x which are positive for every value of x between x_0 and x_1 , are made to turn round the axis of x , the volume limited by the surfaces generated by the two curves, and by the two planes $x = x_0, x = x_1$ will be equal to the difference of the integrals $\pi \int_{x_0}^{x_1} y_1^2 dx$

and $\pi \int_{x_0}^{x_1} y_0^2 dx$, so that if we designate by V this volume we shall have

$$V = \pi \int_{x_0}^{x_1} (y_1^2 - y_0^2) dx = 2\pi \int_{x_0}^{x_1} \int_{y_0}^{y_1} y dy dx.$$

To deduce this formula in a direct manner from the preceding principles, it is sufficient to observe that the volume under consideration being cut by a plane perpendicular to the axis of x , gives for section a zone limited by two circumferences the radii of which coincide with the ordinates y_0 and y_1 , we have therefore, in this case, $F(x) = \pi(y_1^2 - y_0^2)$, and consequently the above expression of the volume V . This volume is precisely that generated by the area U limited, in the plane of x, y , by the curves represented by the equations $y = y_0, y = y_1$ and by the ordinates corresponding to the abscissæ x_0 and x_1 . This understood, let us suppose that the area U is made to slide in the plane of x, y in such a manner as the distance of each point of it to the axis of x increases by the same quantity b , or, which is the same thing, let us suppose that the area B revolves round a line parallel to the axis of x and distant from it by a quantity equal to b . It is obvious that the new solid generated by the revolution of the area U will be a volume equal to the difference

$$\pi \int_{x_0}^{x_1} \{ (y_1 + b)^2 - (y_0 + b)^2 \} dx = \pi \int_{x_0}^{x_1} (y_1^2 - y_0^2) dx + 2\pi \int_{x_0}^{x_1} (y_1 - y_0) dx = V + 2\pi b U.$$

It would be easy to ascertain that the same conclusion would be obtained if the area U were entirely limited by the curves $y = y_0$ and $y = y_1$, or by a single curve. Besides the product $2\pi b$ represents the circumference of a circle which has for its radius the distance b , and the axis of x may coincide with any straight line whatever drawn arbitrarily in the plane of the area U , but entirely out of this area. Hence we may conclude that if a plane surface is made to revolve, 1. round an axis situated in the plane of this area, but entirely out of it, 2. round an axis parallel to the first but more distant from the area, the difference between the volumes generated will be equal to the product of the generating area by the circumference of a circle the radius of which is precisely the distance of the two axes of revolution.

Let us suppose now, that the area U may be divided into two symmetrical parts by a straight line parallel to the axis of x , and distant from it by a quantity equal to b . In this case, the equations of the curves limiting the area U may be written under the following form,

$$y = b - f(x), \quad y = b + f(x),$$

and then

$$V = \pi \int_{x_0}^{x_1} \{ (b + f(x))^2 - (b - f(x))^2 \} dx,$$

or, which is the same thing,

$$V = 4\pi b \int_{x_0}^{x_1} f(x) dx.$$

But we have also

$$U = \int_{x_0}^{x_1} \{ (b + f(x)) - (b - f(x)) \} dx = 2 \int_{x_0}^{x_1} f(x) dx,$$

hence we shall find $V = 2\pi b U$. The same formula subsists when the area U is limited by a single curve, or by several curves joining, provided it may be divided into two symmetrical parts by the straight line $y = b$. Hence, when a plane surface may be divided by a straight line into two symmetrical parts, the solid generated by the revolution of this area round an axis parallel to that line is equal to the product of the area by the circumference of a circle having for radius the distance between the two parallel lines.

Thus, for instance, the solid generated by the revolution of the ellipse represented by the equation $\frac{x^2}{a^2} + \frac{y^2}{b^2} = 1$

round the tangent drawn through one of the extremities of the axis $2b$, is equal to the product obtained in multiplying the surface πab of the ellipse by the circumference $2\pi b$ described by the centre of this curve. Hence the volume V of this body is determined by the equation $V = 2\pi^2 ab^2$.

(409.) Another remarkable theorem results from the formula $V = \int_{x_0}^{x_1} F(x) dx$. Let us consider two parallel

Integral
Calculus.

planes, and parallel to the axis of x , let b be their distance, and let us suppose that a curve is drawn in one of them. If then, from every point of that curve perpendiculars are let fall on the axis, they will generate a surface which together with the two planes will limit a certain volume. Now, this volume is equal to its altitude b multiplied by half the sum of the two bases situated in the two planes. Part III.

To demonstrate this proposition it is sufficient to remark, that if the volume under consideration be cut by a plane perpendicular to the axis of x , the section, the area of which may be as before represented by $F(x)$, will be a trapezium, in which the parallel sides are the linear sections made by this plane in the two bases of the volume. Therefore, if these two linear sections are represented by $f_1(x)$ and $f_2(x)$, we shall have

$$F(x) = \frac{b}{2} (f_1(x) + f_2(x)),$$

and consequently,

$$V = \frac{b}{2} \int_{x_0}^{x_1} \{f_1(x) + f_2(x)\} dx,$$

which equation proves the truth of the theorem stated above.

(410.) To show an application of the formula

$$V = \int_{x_0}^{x_1} \int_{y_0}^{y_1} f(x, y) dy dx,$$

we shall suppose that it is required to find the volume V limited by the plane of x, y , a cylindrical surface of the generating line of which is parallel to the axis of z , and the hyperbolic paraboloid represented by the equation $xy = c^2$. We shall find in this case $f(x, y) = \frac{1}{c} xy$, and consequently,

$$V = \frac{1}{c} \int_{x_0}^{x_1} \int_{y_0}^{y_1} xy dx dy = \frac{1}{2c} \int_{x_0}^{x_1} (y_1^2 - y_0^2) dx dy.$$

If the base of the cylindrical surface is the circumference represented by the equation $(x-a)^2 + (y-b)^2 = r^2$, a and b being two positive quantities greater than r , then

$y_0 = b - \sqrt{r^2 - (x-a)^2}$, $y_1 = b + \sqrt{r^2 - (x-a)^2}$, and $y_1^2 - y_0^2 = 4b\sqrt{r^2 - (x-a)^2}$, $x_0 = a-r$, $x_1 = a+r$, and consequently,

$$V = 2 \frac{b}{c} \int_{a-r}^{a+r} \sqrt{r^2 - (x-a)^2} dx.$$

Then, by assuming $x-a = rt$, we shall have

$$V = 2 \frac{b}{c} r^2 \int_{-1}^{+1} (a+rt) \sqrt{1-t^2} dt.$$

Besides, we have obviously

$$\int_{-1}^{+1} t \sqrt{1-t^2} dt = 0,$$

whilst the integral

$$\int_{-1}^{+1} \sqrt{1-t^2} dt = \frac{\pi}{2}.$$

Hence $V = \pi r^2 \frac{bc}{a}$. Therefore the volume V is equal to the product of the base πr^2 by a fourth proportional to the three lines a, b, c .

If the surface required were to be limited by the same hyperbolic paraboloid, and by four planes perpendicular to the axis of x and y , then the quantities y_0 and y_1 would be constant quantities, and we should find

$$V = \frac{1}{4c} (x_1^2 - x_0^2) (y_1^2 - y_0^2),$$

or which is the same thing,

$$V = (x_1 - x_0) (y_1 - y_0) \frac{x_0 y_0 + x_0 y_1 + x_1 y_0 + x_1 y_1}{4c}.$$

But the product $(x_1 - x_0) (y_1 - y_0)$ represents the surface of the rectangular parallelogram which, in this case, is the base of the volume under consideration. Let

$$\frac{x_0 y_0}{c} = z_1, \quad \frac{x_0 y_1}{c} = z_2, \quad \frac{x_1 y_0}{c} = z_3, \quad \frac{x_1 y_1}{c} = z_4,$$

z_1, z_2, z_3, z_4 , will obviously be the four ordinates of the hyperbolic paraboloid corresponding to the four summits of this rectangular parallelogram, and we shall have

$$V = (x_1 - x_0) (y_1 - y_0) \frac{z_1 + z_2 + z_3 + z_4}{4}.$$

It may be well to remark, that in order to construct the hyperbolic paraboloid which limits this surface, it will be sufficient to join two and two the extremities of the four ordinates z_1, z_2, z_3 , and z_4 , and to suppose that a straight

Integral
Calculus.

line moves in such a manner as to meet two of the opposite sides of the quadrilateral figure so formed, and to be in a plane parallel to the other two sides. Hence the volume limited by the surface so generated, the four planes passing through the sides of the quadrilateral figure, and a fifth plane perpendicular to them, is equal to the product of the rectangular parallelogram which is the base of this volume; multiplied by the fourth part of the sum of the four ordinates corresponding to the four summits of the rectangular base.

(411.) The volume V limited by a given surface, may also be obtained by the following rule.

Let any straight line or axis be drawn, and let us draw in a plane passing through that axis, an auxiliary curve such as the section made in the volume by any plane perpendicular to the axis should always be equal in surface to a rectangular parallelogram having for one of its sides a given line b , and for the other side the linear section made by the same plane in the area drawn on the plane passing through the axis. Then, if we suppose this area limited in the direction of the axis by the two linear sections corresponding to the two extreme positions of the plane supposed to move so as to remain constantly perpendicular to the axis, and to meet the volume under consideration, this volume will be equal to that area multiplied by b .

In order to show the truth of this rule, let us suppose that the axis above mentioned is taken for the axis of x , and if we still call $F(x)$ the area of the section made in this volume by a plane perpendicular to the axis, and

corresponding to the abscissa x , $\frac{F x}{b}$ will be the ordinate of the auxiliary curve; or in other words the linear

section made in the area situated in the plane passing through the axis. Hence this area is equal to

$$\int_{x_0}^{x_1} \frac{F(x)}{b} dx = \frac{1}{b} \int_{x_0}^{x_1} F(x) dx.$$

Now if we multiply this integral by b , we shall find the expression previously found for the volume V .

If the volume V be limited by the surface of a cone or by a pyramid, with any base whatever, and if we take for the axis of the abscissæ a straight line perpendicular to the base, the section $F(x)$ will be proportional to x^2 , and the auxiliary curve will be a parabola the axis of which will be the axis of ordinates. But it has been proved that the area limited by the axis of x , the parabola, and an ordinate, is the third part of the rectangular parallelogram circumscribed to area. This understood, it may be concluded immediately that the volume limited by a cone or a pyramid, is the third part of the cylinder or prism having the same base and same altitude.

If the section $F(x)$ be a trapezium the two parallel sides of which are the linear sections made in two plane surfaces situated in planes parallel to the axis, and if we suppose that b is precisely equal to the distance of the two planes, the ordinate of the auxiliary curve will be precisely half the sum of the linear sections we have just mentioned; hence we shall conclude that the area limited by this auxiliary curve is half the sum of the two plane surfaces, and consequently the theorem of the paragraph (409.)

It would not be more difficult to find by means of the last theorem, the volume limited by two parallel planes, and the surface of a sphere, an ellipsoid, or hyperboloid, &c.

(412.) If the surfaces of the sections of two separate volumes made by a series of parallel planes are in a constant ratio, the two volumes will be to each other in the same ratio.

In order to demonstrate this theorem let us suppose that the different points of space are referred to three rectangular axes, and that the axis of x is perpendicular to the series of parallel planes. If we call $F(x)$ and $f(x)$ the surfaces of the two sections made in the two volumes by one of these planes, namely, by that which corresponds to the abscissa x , we shall have, according to the hypothesis, $F(x) = c f(x)$, c being the constant ratio. Let also x_0 and x_1 be the limits between which the values of the abscissa x must fall, in order that the plane corresponding to that abscissa, and perpendicular to the axis of x , should meet the two volumes. The measure

of the first will be $\int_{x_0}^{x_1} F(x) dx$, and that of the second $\int_{x_0}^{x_1} f(x) dx$, but since $F(x) = c f(x)$, we shall also

have $\int_{x_0}^{x_1} f(x) dx = \frac{1}{c} \int_{x_0}^{x_1} F(x) dx$, which formula agrees with the theorem stated at the beginning of this paragraph.

Hence we may conclude that two volumes are equivalent when the sections made in them by a series of parallel planes are equal in surface.

Let us next consider the sphere represented by the equation $x^2 + y^2 + z^2 = a^2$, and the ellipsoid represented by $\frac{x^2}{a^2} + \frac{y^2}{b^2} + \frac{z^2}{c^2} = 1$. It is obvious that the section made in these two bodies by a plane perpendicular to the

axis of x , and corresponding to the abscissa x , are for the first a circle the radius of which is $(a^2 - x^2)^{\frac{1}{2}}$, and for

the second an ellipse the semi-axes of which are $\frac{b}{a}(a^2 - x^2)^{\frac{1}{2}}$, and $\frac{c}{a}(a^2 - x^2)^{\frac{1}{2}}$; the surface of the first section is

therefore $\pi(a^2 - x^2)$, and that of the second $\frac{\pi b c}{a^2}(a^2 - x^2)$, the ratio of which is that of a^2 to $b c$. Hence we

shall conclude that the volume of the sphere $\frac{4}{3} \pi a^3$ is to that of the ellipsoid as $a^2 : b c$, and therefore that this

last volume is $\frac{4}{3} \pi a b c$. The same ratio subsists clearly between two segments of the sphere and ellipsoid limited by any two parallel planes.

(413.) If we suppose a line to move so as to remain parallel to a given axis, and, if we suppose, besides, that the lengths of this line, intercepted by two separate volumes, in every position, have a constant ratio, then we may conclude that this ratio is also the ratio of the two volumes.

Let, as before, the points of space be referred to three rectangular axes, and let the axis of z be parallel to the line that is supposed to move. This understood, let $f_1(x, y)$, $f_2(x, y)$ be the lengths of that straight line intercepted by the two volumes in any particular position. We shall have, according to the hypothesis $f_1(x, y) = c f_2(x, y)$, c being the constant ratio. Let also x_0, x_1 be constant quantities, and y_0 and y_1 be functions of x such as the equations $x = x_0, x = x_1, y = y_0, y = y_1$, be those of the planes and cylindrical surfaces which limit the space in which the moving line ought to remain in order to meet the two volumes. The first

volume, according to what precedes, will have for its measure $\int_{x_0}^{x_1} \int_{y_0}^{y_1} f_1(x, y) dy dx$, and the second $\int_{x_0}^{x_1} \int_{y_0}^{y_1} f_2(x, y) dy dx$, therefore since $f_1(x, y) = c f_2(x, y)$, we shall have also the first volume equal to the product of the second by c .

The preceding demonstration would not apply if each of the given volumes could be met in several points by a line parallel to the axis of x , or to the axis of y . But then it would be easy to decompose the two volumes into corresponding parts, the ratio of which determined by the preceding reasonings would be equal to c ; and, since when the parts of a sum increase or decrease in the ratio of 1 to c , this sum increases or decreases in the same ratio, it is obvious that the theorem would still be true.

The same theorem would also hold in the case where the lengths $f_1(x, y)$, $f_2(x, y)$ would be composed of several separate lengths, the first included between two given surfaces, the second between two other given surfaces, &c. Let us consider two surfaces each of which completely limits a volume. Let the equation of the

first surface be $f(x, y, z) = 0$, and that of the second $f\left(x, y, \frac{z}{c}\right) = 0$. It is clear that for each system of values

given to x and y , will be derived from these two equations corresponding values of z which will be to each other in the ratio of 1 to c . Hence the limits which the values of x and y ought not to exceed, in order that the values of z should be real, will not change when one of these surfaces is substituted for the other. Moreover, if we designate by $z_0, z_1, z_2, z_3, \dots$ &c. the various real values of z , furnished by the first equation for a given system of values of x and y , those corresponding to the same system given by the second equation will obviously be $c z_0, c z_1, c z_2, c z_3, \dots$ &c. If, besides, we suppose the quantities $z_0, z_1, z_2, z_3, \dots$ &c. to be arranged according to their magnitude, the total length which may be represented by $\phi_1(x, y)$ of the portion of the parallel to the axis of z , corresponding to the system of values of x and y under consideration, contained within the first surface, will be $\phi_1(x, y) = z_1 - z_0 + z_3 - z_2 + \dots$, and for the second the total length corresponding represented by $\phi_2(x, y)$ is equal to $c z_1 - c z_0 + c z_3 - c z_2 + \dots = c(z_1 - z_0 + z_3 - z_2 + \dots)$; we shall have, therefore, $\phi_2(x, y) = c \phi_1(x, y)$, and consequently according to the theorem demonstrated above, we may conclude that the volume limited by the surface represented

by the equation $f\left(x, y, \frac{z}{c}\right) = 0$, is equal to the product of the volume limited by the surface represented by the equation $f(x, y, z) = 0$, multiplied by c . In the same manner it might be proved that the volumes limited by the surfaces $f\left(\frac{x}{a}, y, z\right) = 0$, $f\left(x, \frac{y}{b}, z\right) = 0$ are respectively equal to the volume limited by the surface $f(x, y, z) = 0$ multiplied by a and b .

If now we compare the volumes limited by the surfaces represented by the equations

$$f(x, y, z) = 0, \quad f\left(\frac{x}{a}, y, z\right) = 0, \quad f\left(\frac{x}{a}, \frac{y}{b}, z\right) = 0, \quad f\left(\frac{x}{a}, \frac{y}{b}, \frac{z}{c}\right) = 0,$$

we shall easily establish that the second is equal to the product of the first by a , the third to the product of the second by b , and the fourth to the product of the third by c . Hence the last is equal to the product of the first by $a b c$.

Therefore, in general, to find the volume limited entirely by a surface represented by the equation $f\left(\frac{x}{a}, \frac{y}{b}, \frac{z}{c}\right) = 0$, it is sufficient to find the volume limited by the surface represented by the equation $f(x, y, z) = 0$, and to multiply it by $a b c$.

From this general theorem it is easy to deduce the volume of the ellipsoid represented by the equation

$$\frac{x^2}{a^2} + \frac{y^2}{b^2} + \frac{z^2}{c^2} = 1 \text{ from the volume of the sphere represented by the equation } x^2 + y^2 + z^2 = 1.$$

If we suppose $a = b = c$, then we see that the surface represented by the equation $f\left(\frac{x}{a}, \frac{y}{a}, \frac{z}{a}\right) = 0$ is similar to the surface represented by the equation $f(x, y, z) = 0$, and we conclude from the preceding theorem that the volumes limited by two similar surfaces are to each other as the cubes of their linear dimensions.

CALCULUS OF VARIATIONS.

Calculus of Variations. (414.) IN the problems of Maxima and Minima which have been treated in the preceding pages, the relation between the function and the variable is either immediately known, or is determined by means of some equation of condition arising from the nature of the question; and the problem is easily solved by the ordinary rules. But there is a numerous class of problems, and of vast variety, in which not only is the property of a maximum or minimum to be recognised, but the particular function to be investigated in which this property takes place. Part III.

For example, if it be required to find the shortest distance between two known curves, we must first discover the species of curve to which this property belongs, and then find the least distance.

As a further illustration, let us suppose V to be a function of $x, y, p, q, \&c.$, where $p, q, \&c.$, are the differential coefficients of y with regard to x . The integral $\int V dx$, taken between the same values of x , as a and a_1 , is susceptible of an infinite number of values, dependent upon the relation between y and x ; we may therefore ask what particular equation between these quantities y and x will make $\int V dx$ to become a maximum or minimum. And, here, whether the question be of the least length, between two points, or of the greatest volume, or surface, or any other possible condition, it is obvious that in causing the ordinate y or the abscissa x to vary we must be enabled to pass from one curve or function to another: and the first thing which must be done will be to investigate the change that takes place in the function $\int V dx$, when y and x have changed according to the manner here hinted at.

Problems of this description early occupied the attention of the Mathematicians, who perfected and practised the new Calculus which the genius of Newton had invented, and the notation of Leibnitz had rendered universally acceptable.

But as it would exceed the limits prescribed to us, were we to undertake the task of presenting to the reader even a short account of the methods by which the Bernouillis and Euler solved these problems, or of following them through their laborious efforts to perfect the processes which were at first rude, and sometimes inapplicable, we shall confine ourselves to the method which, under the name of the Calculus of Variations, owes its invention to Lagrange, and of which the notation is not one of the least of its excellencies.

(415.) In this Calculus, the change which the function undergoes in consequence of the alteration in the value of y is called variation, and variation bears to the function the same relation that differentiation does to the original function in the Differential Calculus; in fact, it has been defued to be differentiation under a new symbol. The distinction, however, between the operations may be illustrated by means of a curve.

Suppose we wish to find the shortest distance between two points, of which the coordinates are given.

If C and D be the two given points, (fig. 1.) innumerable curves may be drawn from C to D , and we have to find which of these curves possesses the required property. We must, therefore, in our reasoning pass from one curve to another; as, for instance, from a point P in one curve to a point Q in a curve above it. This change from P to Q is called a variation of the ordinate NP , while a change from P to P_1 , or from Q to Q_1 , P_1 and Q_1 being consecutive points to P and Q respectively, in the curves which are the loci of P and Q , is merely a differentiation of the ordinates NP and NQ .

The symbol (δ) is used to express the variation or change from P to Q , and thus, while dy expresses the alteration of the ordinate y , by passing from one point to another in the same curve, δy represents the alteration of the ordinate when its extremity passes from one curve to another; but δ has also a more extended meaning, as we shall see hereafter: in this case, however,

$$\begin{aligned} \text{If} \quad & NP = y, \quad MP_1 = y + dy \\ \text{and, since} \quad & PQ = \delta y, \quad NQ = y + \delta y. \end{aligned}$$

(416.) From the preceding illustration may be proved a theorem of which great use is made in the Calculus.

$$\begin{aligned} \text{Since} \quad & NQ = y + \delta y \therefore MQ_1 = NQ + d \cdot NQ = (y + \delta y) + d \cdot (y + \delta y) \\ \text{And} \quad & \therefore MP_1 = y + dy \therefore MQ_1 = MP_1 + \delta \cdot MP_1 = y + dy + \delta(y + dy) \\ & \therefore y + \delta y + dy + d\delta y = y + dy + \delta y + \delta dy. \\ & \therefore d\delta y = \delta dy; \end{aligned}$$

whence it appears that the symbols of differentiation and of variation are interchangeable.

Hence, also, if for y we put dy , we have

$$\begin{aligned} d\delta dy &= \delta d^2 y, \quad \text{or, since } d\delta dy = dd\delta y, \\ \therefore d^2 \delta y &= \delta d^2 y, \text{ and similarly } d^n \delta y = \delta d^n y. \end{aligned}$$

These theorems may, however, be proved without the illustration of the curve. For if $y_1 = \text{value of } y + dy$,

$$\delta dy = \delta(y_1 - y) = \delta y_1 - \delta y = d\delta y.$$

(417.) But, to return to the definition of a variation, we instantly perceive that the processes of the Differential Calculus immediately apply, and thus to obtain the variation of a function of y we must write $y + \delta y$ for y , and having expanded the new function according to the powers of δy , subtract from it the original function, and the first term of the difference will be the variation required. Hence, it appears that the first differential coefficient of the function multiplied by δy is the variation of the function.

Thus, if $u = y^n$, the difference of $u = (y + \delta y)^n - y^n$.

$$\therefore \delta u = \text{first term of difference} = ny^{n-1} \cdot \delta y = \frac{du}{dy} \delta y.$$

and
VOL. II.

Also, since if $u = f(x, y, p, q, \&c.)$ where $p, q, \&c.$, are the differential coefficients of y with respect to x ,

$$du = \frac{du}{dx} dx + \frac{du}{dy} dy + \frac{du}{dp} dp + \frac{du}{dq} dq + \&c.$$

or putting

$$M = \frac{du}{dx}, \quad N = \frac{du}{dy}, \quad P = \frac{du}{dp}, \quad Q = \frac{du}{dq}, \quad \&c.$$

$$du = M dx + N dy + P dp + Q dq + \&c.$$

and $\therefore$ by the rule just enunciated, the variation of u or

$$\delta u = M \delta x + N \delta y + P \delta p + Q \delta q + \&c.$$

(418.) In the proof of the theorem $d \delta y = \delta d y$, it has been assumed that the ordinate y alone varied, and that the abscissa x remained constant, but, as we may readily perceive, cases may occur in which both these quantities vary. Such a case will always take place when in consequence of variation the point P is transferred to another point in the curve above it, which is to the left or the right of Q ; the variation may then be conceived to be made up of two variations, one of which is in the direction of the ordinate and the other perpendicular to it. We now proceed to show that whatever be the function u , $\delta d u = d \delta u$.

(419.) Suppose, then, that u be any function whatever of the variables $x, y, dx, dy, d^2x, d^2y, \&c.$, its variation is therefore to be found, by writing instead of $x, dx, d^2x, \&c.$, $y, dy, d^2y, \&c.$, the quantities

$$x + \delta x, \quad dx + \delta dx, \quad d^2x + \delta d^2x, \quad \&c.$$

$$y + \delta y, \quad dy + \delta dy, \quad d^2y + \delta d^2y, \quad \&c.;$$

and then subtracting u from the result, and stopping at the terms which involve the first powers of the variations; but this process will be rendered more easy if, instead of $dx, d^2x, \&c.$, $dy, d^2y, \&c.$, we put $x_1, x_2, \&c.$, $y_1, y_2, \&c.$, and then u will become a function of $x, x_1, x_2, \&c.$ and $y, y_1, y_2, \&c.$; and we shall therefore have

$$du = \frac{du}{dx} dx + \frac{du}{dx_1} dx_1 + \frac{du}{dx_2} dx_2 + \&c. \\ + \frac{du}{dy} dy + \frac{du}{dy_1} dy_1 + \frac{du}{dy_2} dy_2 + \&c.;$$

and from what we have said in our definition of a variation, that it is equal to the product of the differential coefficient by the variation of the variable,

$$\therefore \delta u = \frac{du}{dx} \delta x + \frac{du}{dx_1} \delta x_1 + \frac{du}{dx_2} \delta x_2 + \&c. \\ + \frac{du}{dy} \delta y + \frac{du}{dy_1} \delta y_1 + \frac{du}{dy_2} \delta y_2 + \&c.$$

Keeping this definition in view, we must now find the $\delta \cdot du$ and $d \cdot \delta u$: to do this it will be better to find the variation of each term separately, considering each differential coefficient $\frac{du}{dx}, \frac{du}{dx_1}, \frac{du}{dx_2}, \&c.$, to be functions of $x, x_1, x_2, \&c.$

Now

$$\delta \cdot \frac{du}{dx} dx = \frac{du}{dx} \delta dx + \frac{d^2u}{dx^2} \delta x dx + \frac{d^2u}{dx dx_1} \delta x_1 dx + \&c. \\ = \frac{du}{dx} \delta dx + dx \left\{ \frac{d^2u}{dx^2} \delta x + \frac{d^2u}{dx dx_1} \delta x_1 + \&c. \right\}$$

And

$$\delta \frac{du}{dx_1} dx_1 = \frac{du}{dx_1} \delta dx_1 + dx_1 \left\{ \frac{d^2u}{dx dx_1} \delta x + \frac{d^2u}{dx_1^2} \delta x_1 + \&c. \right\} \\ \&c. = \&c. + \&c. \\ \therefore \delta \cdot du = \frac{du}{dx} \delta dx + dx \left\{ \frac{d^2u}{dx^2} \delta x + \frac{d^2u}{dx dx_1} \delta x_1 + \&c. \right\} \\ + \frac{du}{dx_1} \delta dx_1 + dx_1 \left\{ \frac{d^2u}{dx dx_1} \delta x + \frac{d^2u}{dx_1^2} \delta x_1 + \&c. \right\} \\ + \&c. \dots + \&c.$$

Next, to find the $d \delta u$; differentiating the terms separately.

$$d \cdot \frac{du}{dx} \delta x = \frac{du}{dx} d \cdot \delta x + \frac{d^2u}{dx^2} dx \delta x + \frac{d^2u}{dx dx_1} dx_1 dx + \&c. \\ = \frac{du}{dx} d \delta x + \delta x \left\{ \frac{d^2u}{dx^2} dx + \frac{d^2u}{dx dx_1} dx_1 + \&c. \right\}$$

And

$$d \cdot \frac{du}{dx_1} \delta x_1 = \frac{du}{dx_1} d \delta x_1 + \delta x_1 \left\{ \frac{d^2u}{dx dx_1} dx + \frac{d^2u}{dx_1^2} dx_1 + \&c. \right\} \\ \therefore d \delta u = \frac{du}{dx} d \delta x + \delta x \left\{ \frac{d^2u}{dx^2} dx + \frac{d^2u}{dx dx_1} dx_1 + \&c. \right\}$$

Calculus of Variations.

$$\frac{du}{dx_1} d\delta x_1 + \delta x_1 \left\{ \frac{d^2 u}{dx dx_1} dx + \frac{d^2 u}{dx_1^2} dx_1 + \&c. \right\} \\ + \&c. \quad + \&c.$$

whence

and writing du for u we have also

$$\delta \cdot d^2 u = d \cdot \delta du = \delta^2 du, \text{ and finally } \delta \cdot d^n u = d^n \delta u.$$

Hence, in general, whatever be the value of u , the symbols δ and d are interchangeable, or the variation of the differential gives the same result as the differential of the variation.

Example 1. Let

$$u = y^n \therefore du = n y^{n-1} dy \text{ and } \delta u = n y^{n-1} \delta y$$

$$\therefore \delta du = n y^{n-1} \delta dy + n(n-1) y^{n-2} \delta y dy$$

$$d \cdot \delta u = n y^{n-1} d \delta y + n(n-1) y^{n-2} \delta y dy$$

and

$$\therefore \delta dy = d \delta y \therefore \delta du = d \delta u.$$

Example 2. Let

$$u = x^2 + y^2.$$

$$\therefore du = 2x dx + 2y dy$$

and

$$\delta u = 2x \delta x + 2y \delta y$$

$$\therefore \delta du = 2x \delta dx + 2y \delta dy + 2\delta x dx + 2\delta y dy,$$

and

$$d \cdot \delta u = 2x d \delta x + 2y d \delta y + 2\delta x dx + 2\delta y dy;$$

whence

$$\therefore \delta dx = d \delta x, \text{ and } d \delta y = \delta dy \therefore \delta du = d \delta u.$$

(420.) There is also a similar theorem with respect to the sign of integration, namely, that $\delta \int u = \int \delta u$, or the variation of the integral of a function is equal to the integral of the variation of the function.

To prove this theorem, let $\int u = u_1 \therefore u = du_1$

$$\therefore \delta u = \delta du_1 = d \delta u_1$$

And

the theorem required.

$$\therefore \int \delta u = \int d \delta u_1 = \delta u_1 = \delta \int u,$$

Similarly

$$\int^2 \delta u = \int^2 \delta \int u = \delta \int \int u = \delta \int^2 u,$$

and thus we at length arrive at the equation $\int^n \delta u = \delta \int^n u$.

(421.) Having proved these preliminary theorems, we now proceed to apply them to find the variation of $\int u$, and, in the first instance, let u depend not only on y and its differential coefficients, but upon x and its differential coefficients also. Let, then, u be any function whatever of the variables x and y , and of their differentials, such that

$$du = M dx + N d^2 x + P d^3 x + Q d^4 x + \&c. \\ + m dy + n d^2 y + p d^3 y + q d^4 y + \&c.$$

Then we have, since $d^2 x = d \cdot dx$, $d^3 x = d \cdot d^2 x$, &c.

$$\delta u = M \delta x + N \delta dx + P \delta d^2 x + Q \delta d^3 x + \&c. \\ + m \delta y + n \delta dy + p \delta d^2 y + q \delta d^3 y + \&c.$$

and, consequently,

$$\int \delta u = \int (M \delta x + N \delta dx + P \delta d^2 x + Q \delta d^3 x + \&c.) \\ + \int (m \delta y + n \delta dy + p \delta d^2 y + q \delta d^3 y + \&c.)$$

Now, by transposing the δ and d , i. e. putting δ after d , and integrating by parts, the terms δx and δy may be freed from the sign of differentiation, and the formula for $\int \delta u$ be reduced to a more simple form: thus,

$$\int N \delta dx = \int N d \delta x = N \delta x - \int d N \delta x \\ \int P \delta d^2 x = \int P d^2 \delta x = P d \delta x - \int d P d \delta x \\ = P d \delta x - d P \delta x + \int d^2 P \delta x \\ \int Q \delta d^3 x = \int Q d^3 \delta x = Q d^2 \delta x - \int d Q \cdot d^2 \delta x \\ = Q d^2 \delta x - d Q d \delta x + \int d^2 Q d \delta x \\ = Q d^2 \delta x - d Q d \delta x + d^2 Q \cdot \delta x - \int d^3 Q \delta x \\ \&c. \quad \&c.$$

In the same manner,

$$\int n \delta dy = \int n d \delta y = n \delta y - \int d n \cdot \delta y \\ \int p \delta d^2 y = \int p d^2 \delta y = p d \delta y - d p \delta y + \int d^2 p \delta y \\ \int q \delta d^3 y = \int q d^3 \delta y = q d^2 \delta y - d q d \delta y + d^2 q \cdot \delta y - \int d^3 q \cdot \delta y, \\ \&c. \quad \&c.;$$

and substituting these values in the expression for $\int \delta u$, we have

$$\int \delta u = (N - d P + d^2 Q - \&c.) \delta x + (n - d p + d^2 q - \&c.) \delta y \\ + (P - d Q + \&c.) d \delta x + (p - d q + \&c.) d \delta y \\ + (Q - d R + \&c.) d^2 \delta x + (q - d r + \&c.) d^2 \delta y \\ + \&c. \quad + \&c.$$

$$+ \int (M - dN + d^2P - d^3Q + \&c.) \delta x \\ + \int (m - dn + d^2p - d^3q + \&c.) \delta y.$$

(422.) The result which we have obtained is composed of two similar parts, one of which is due to the variation of x , and the other to the variation of y : hence, we perceive, that if u be a function of x, y, z , or of any number of variables, we may derive from the preceding expression the value of the variation of $\int u$, by adding to it, for each new variable, a series of terms similar to that which the variable x has produced.

Thus, let u be a function of x, y, z , in which case

$$du = Mdx + Nd^2x + Pd^3x + Qd^4x + \&c. \\ + mdy + nd^2y + pd^3y + qd^4y + \&c. \\ + \mu dz + \nu d^2z + \pi d^3z + \rho d^4z + \&c.;$$

then, for the new variable z , we shall have to add the terms

$$(\nu - d\pi + d^2\rho - \&c.) \delta z + (\pi - d\rho + \&c.) d\delta z + \&c. \\ + \int (\mu - d\nu + d^2\pi - d^3\rho + \&c.) \delta z.$$

It must be observed that, in the preceding investigations, y and x , as also y, x , and z , are independent of each other, but may be considered as functions of another variable, as t , which is understood.

Let us consider y and x only, and let y be a function of x , then dx is constant, and

$$du = Mdx \\ + mdy + nd^2y + pd^3y + qd^4y + \&c.$$

and the variation of the $\int u$ is reduced to

$$(n - dp + d^2q - \&c.) \delta y + (p - dq + \&c.) d\delta y + (q - \&c.) d^2\delta y + \&c. \\ + \int M\delta x \\ + \int (m - dn + d^2p - d^3q + \&c.) \delta y,$$

which may be again simplified, since u may be put equal to Vdx ,

and

$$\therefore M = \frac{dV}{dx} dx, \text{ since } \frac{du}{dx} = \frac{dV}{dx} dx;$$

consequently,

$$\int M\delta x = \int \frac{dV}{dx} dx \cdot \delta x = \\ = V\delta x - \int Vd\delta x = V\delta x - \int V\delta dx \\ = V\delta x.$$

Since, if $dx = \text{a constant}$, $\delta dx = 0$, and thus the only terms which remain under the sign of integration are those which are multiplied by δy .

(423.) As an Example of the use of this theorem, let

$$u = \frac{\sqrt{dx^2 + dy^2}}{\sqrt{y}} = \frac{ds}{\sqrt{y}} \\ \therefore \delta u = \sqrt{dx^2 + dy^2} \cdot \delta \frac{1}{\sqrt{y}} + \frac{1}{\sqrt{y}} \delta \sqrt{dx^2 + dy^2};$$

and performing the variations as if we were to obtain differentials

$$\delta \frac{1}{\sqrt{y}} = -\frac{\delta y}{2y^{\frac{3}{2}}}, \delta \sqrt{dx^2 + dy^2} = \frac{dx\delta dx + dy\delta dy}{\sqrt{dx^2 + dy^2}} \\ \therefore \delta u = -\frac{\delta y \cdot ds}{2y^{\frac{3}{2}}} + \frac{dx \cdot \delta dx}{\sqrt{y} \cdot ds} + \frac{dy \delta dy}{\sqrt{y} \cdot ds}$$

Comparing this with the general formula for δu , we have

$$M = 0, m = -\frac{ds}{2y^{\frac{3}{2}}}, N = \frac{dx}{\sqrt{y} \cdot ds}, n = \frac{dy}{\sqrt{y} \cdot ds}$$

and

$$\therefore \delta \int u = N\delta x + n\delta y + \int (-dN)\delta x + \int (m - dn)\delta y \\ = \frac{dx}{\sqrt{y} \cdot ds} \delta x + \frac{dy}{\sqrt{y} \cdot ds} \delta y \\ - \int \left\{ \frac{ds}{2y^{\frac{3}{2}}} \delta y + d \cdot \left(\frac{dy}{\sqrt{y} \cdot ds} \right) \delta y + d \cdot \left(\frac{dx}{\sqrt{y} \cdot ds} \right) \delta x \right\}$$

This method of finding the variation of u is due to Lagrange. Euler, however, has given to it another and more convenient form for the solution of the problems, to which our attention will be directed. Instead of u he put Vdx where V is supposed to be a function of x, y , and the differential coefficients of y with regard to x .

Calculus of Variations. (424.) We proceed, therefore, on this new supposition, to find the variation of $\int V dx$, when y is a function of x , but the reasoning is only applicable when u can be put under the form $V dx$. Part III.

Let

$$dV = M dx + N dy + P dp + Q dq + R dr + \&c.$$

where

$$p = \frac{dy}{dx}, q = \frac{d^2y}{dx^2}, r = \frac{d^3y}{dx^3}, \&c. = \&c.$$

and

$$M = \frac{dV}{dx}, N = \frac{dV}{dy}, P = \frac{dV}{dp}, Q = \frac{dV}{dq}, \&c.$$

Then

$$\delta V = M \delta x + N \delta y + P \delta p + Q \delta q + \&c.,$$

where $M, N, P, Q, \&c.$, are the same as in the equation for dV .

Now

$$\begin{aligned} \delta \int V dx &= \int \delta V dx = \int (V \delta dx + dx \delta V) \\ &= \int (V d\delta x + dx \delta V) \\ &= \int V d\delta x + \int dx \delta V \\ &= V \delta x + \int (dx \delta V - \delta x dV). \end{aligned}$$

and putting instead of δV and dV their values, we have

$$\begin{aligned} \int (dx \delta V - \delta x dV) &= \int dx (M \delta x + N \delta y + P \delta p + Q \delta q + \&c.) \\ &\quad - \int \delta x (M dx + N dy + P dp + Q dq + \&c.) \\ &= \int N dx (\delta y - p \delta x) + \int P dx (\delta p - q \delta x) + \int Q dx (\delta q - r \delta x) + \&c. \\ &\quad + \int R dx (\delta r - s \delta x) + \&c. \end{aligned}$$

We must now endeavour to find the forms of $\delta p - q \delta x$, $\delta q - r \delta x$, $\&c.$, and we shall see that each of these factors depends upon $\delta y - p \delta x$.

Since

$$\frac{dy}{dx} = p, \frac{dp}{dx} = q, \frac{dq}{dx} = r, \&c. = \&c.$$

$$\therefore \delta p = \frac{dx \delta dy - dy \delta dx}{dx^2} = \frac{\delta dy - p \delta dx}{dx} = \frac{d\delta y - p d\delta x}{dx}.$$

$$\therefore \delta p - q \delta x = \frac{\delta dy - p \delta dx - d p \delta x}{dx} = \frac{d\delta y - d.p \delta x}{dx} = \frac{d(\delta y - p \delta x)}{dx}$$

$$\delta q = \delta \frac{dp}{dx} = \frac{dx \delta dp - dp \delta dx}{dx^2} = \frac{\delta dp - q \delta dx}{dx} = \frac{d\delta p - q d\delta x}{dx}$$

$$\therefore \delta q - r \delta x = \delta q - \frac{dq}{dx} \delta x = \frac{d\delta p - q d\delta x - dq \delta x}{dx} = \frac{d(\delta p - q \delta x)}{dx}$$

also

$$\delta r = \delta \frac{dq}{dx} = \frac{dx \delta dq - dq \delta dx}{dx^2} = \frac{d\delta q - r d\delta x}{dx}$$

$$\therefore \delta r - s \delta x = \frac{d\delta q - r d\delta x - dr \delta x}{dx} = \frac{d(\delta q - r \delta x)}{dx}.$$

Now make

$$\delta y - p \delta x = w$$

$$\therefore \delta p - q \delta x = \frac{dw}{dx}.$$

$$\delta q - r \delta x = \frac{d\left(\frac{dw}{dx}\right)}{dx} = \frac{d^2w}{dx^2}.$$

and

$$\begin{aligned} \delta r - s \delta x &= \frac{d\left(\frac{d^2w}{dx^2}\right)}{dx} = \frac{d^3w}{dx^3}. \\ \&c. &= \&c. \end{aligned}$$

$\therefore$ Substituting these values in the expression for $\delta \int (dx \delta V - dV \delta x)$, and adding $V \delta x$, we have

$$\delta \int V dx = V \delta x + \int N w dx + \int P dw + \int Q \frac{d^2w}{dx^2} + \int R \frac{d^3w}{dx^3} + \&c.$$

Then integrating by parts

$$\begin{aligned} \int P dw &= Pw - \int \frac{dP}{dx} w dx \\ \int Q \frac{d^2w}{dx^2} &= Q \frac{dw}{dx} - \int \frac{dQ}{dx} dw \end{aligned}$$

Calculus of
Variations.

$$\begin{aligned}
&= Q \frac{dw}{dx} - w \frac{dQ}{dx} + \int \frac{d^2 Q}{dx^2} w dx \\
\int R \frac{d^2 w}{dx^2} &= R \frac{d^2 w}{dx^2} - \int \frac{dR}{dx} \cdot \frac{dw}{dx} \\
&= R \frac{d^2 w}{dx^2} - \frac{dR}{dx} \cdot \frac{dw}{dx} + \int \frac{d^2 R}{dx^2} \cdot dw \\
&= R \frac{d^2 w}{dx^2} - \frac{dR}{dx} \frac{dw}{dx} + \frac{d^2 R}{dx^2} w - \int \frac{d^3 R}{dx^3} w dx.
\end{aligned}$$

&c. = &c.

$$\begin{aligned}
\therefore \delta \int V dx &= V \delta x + \left(P - \frac{dQ}{dx} + \frac{d^2 R}{dx^2} - \&c. \right) w \\
&\quad + \left(Q - \frac{dR}{dx} + \frac{d^2 S}{dx^2} - \&c. \right) \frac{dw}{dx} \\
&\quad + \left(R - \frac{dS}{dx} + \&c. \right) \frac{d^2 w}{dx^2} \\
&\quad + \&c. \\
&\quad + \int \left(N - \frac{dP}{dx} + \frac{d^2 Q}{dx^2} - \frac{d^3 R}{dx^3} + \&c. \right) w dx.
\end{aligned}$$

(425.) Hence we see that the variation of $\int V dx$ consists of two distinct parts, one of which is under the sign of integration, and the other is not. The latter of which is effected only by the variations of the extreme values of y and x , the former depends upon all the values between these extreme ones. Suppose the extreme values of x and y be x_1, y_1 , and x_2, y_2 ; then the total variation of $\int V dx$.

$$\begin{aligned}
&= V_2 \delta x_2 - V_1 \delta x_1 + \left(P_2 - \frac{dQ_2}{dx_2} + \frac{d^2 R_2}{dx_2^2} - \&c. \right) w_2 \\
&\quad - \left(P_1 - \frac{dQ_1}{dx_1} + \frac{d^2 R_1}{dx_1^2} - \&c. \right) w_1 \\
&\quad + \left(Q_2 - \frac{dR_2}{dx_2} + \frac{d^2 S_2}{dx_2^2} - \&c. \right) \frac{dw_2}{dx_2} \\
&\quad - \left(Q_1 - \frac{dR_1}{dx_1} + \frac{d^2 S_1}{dx_1^2} - \&c. \right) \frac{dw_1}{dx_1} \\
&\quad + \&c. \\
&\quad + \int \left(N - \frac{dP}{dx} + \frac{d^2 Q}{dx^2} - \frac{d^3 R}{dx^3} + \&c. \right) w dx.
\end{aligned}$$

The part under the sign of integration being taken between the same limits.

(426.) If $w = 0$, the formula is reduced to $V \delta x$, but since, if

$$w = 0, \delta y - p \delta x = 0 \therefore \frac{\delta y}{\delta x} = p = \frac{dy}{dx}.$$

there is the same relation between δy and δx as there is between dy and dx , and $\therefore$ the same result ought to be obtained as that arising from ordinary differentiation, and we know that $d \int V dx = V \cdot dx$, the symbols d and $\int$ indicating inverse operations.

(427.) It is obvious, that if u had been a function of three variables x, y, z , instead of the two variables x and y only, and if we still consider x to be the independent variable, then, since the differential of V can be put under the form

$$dV = M dx + N dy + P dp + Q dq + \&c.$$

and

$$\begin{aligned}
&+ N_1 dz + P_1 dp_1 + Q_1 dq_1 + \&c. \\
\therefore \delta V &= M \delta x + N \delta y + P \delta p + Q \delta q + \&c. \\
&+ N_1 \delta z + P_1 \delta p_1 + Q_1 \delta q_1 + \&c.
\end{aligned}$$

we should have for the new variable z a set of terms involving $N_1, P_1, Q_1, \&c.$, precisely similar to those in which $N, P, Q, \&c.$, are introduced; and, making $\delta z - p_1 \delta x = w_1$, the total variation will be found to be expressed by

$$\begin{aligned}
\delta \int V dx &= V \delta x + \left(P - \frac{dQ}{dx} + \frac{d^2 R}{dx^2} - \&c. \right) w \\
&\quad + \left(Q - \frac{dR}{dx} + \frac{d^2 S}{dx^2} - \&c. \right) \frac{dw}{dx} \\
&\quad + \&c. + \left(P_1 - \frac{dQ_1}{dx} + \frac{d^2 R_1}{dx^2} - \&c. \right) w_1
\end{aligned}$$

Calculus of Variations.

$$\begin{aligned}
 & + \left(Q_1 - \frac{d R_1}{d x} + \&c. \right) \frac{d w_1}{d x} + \&c. \\
 & + \int \left(N - \frac{d P}{d x} + \frac{d^2 Q}{d x^2} - \frac{d^3 R}{d x^3} + \&c. \right) w d x \\
 & + \int \left(N_1 - \frac{d P_1}{d x} + \frac{d^2 Q_1}{d x^2} - \frac{d^3 R_1}{d x^3} + \&c. \right) w_1 d x.
 \end{aligned}$$

(428.) In the preceding investigations we have not supposed that the coordinates of the limits enter into the functions which are under the sign $\int$; but there are questions in which these coordinates do vary, as we shall see in the succeeding pages. If, then, the function V does also contain these coordinates and their differentials,

there must be added to the expression for δV a series of terms of the form $\frac{d V}{d x_1} \delta x_1 + \frac{d V}{d y_1} \delta y_1 + \&c.$; and $\therefore$

to the part under the integral sign there will also be added the term $\int \left(\frac{d V}{d x_1} \delta x_1 + \frac{d V}{d y_1} \delta y_1 + \&c. \right) d x$, but as the variations $\delta x_1, \delta y_1, \&c.$, are independent of the indeterminate quantities x and y , they may be put without the sign of integration, and may be written $\delta x_1 \int \frac{d V}{d x_1} d x + \delta y_1 \int \frac{d V}{d y_1} d x + \&c.$, and may be considered to belong to the first part of the expression for the $\delta \int V d x$.

APPLICATION OF THE CALCULUS OF VARIATIONS TO QUESTIONS OF MAXIMA AND MINIMA.

(429.) WE now proceed to the application of the formulæ, which have been deduced in the preceding articles, to those questions of Geometry which by its means find a ready solution. The principles, which, in the Differential Calculus, have guided us to the detection of these tests, by which the existence of a maximum or minimum state of a function may be known, are applicable here.

If there be any function u of the quantities $x, y, dx, dy, \&c.$, the result of the substitution of $x + \delta x, y + \delta y, dx + \delta dx, dy + \delta dy, \&c.$, by stopping at the first terms of the variations, $\delta x, \delta y, \delta dx, \delta dy, \&c.$, will give us the variation of u .

But, as the variation of u only involves the first powers of $\delta x, \delta y, \&c.$, it is clear that the terms which are affected by these variations will change their signs at the same time as the variations change: hence, if u be a maximum or minimum $\delta u = 0$. Now, suppose $u = \int u$, or $\int V d x$; therefore, at a maximum or maximum, $\delta \int u = 0$ or $\delta \int V d x = 0$, according as $u = \int u$ or $u = \int V d x$.

We must not, however, suppose that whenever $\delta \int V d x = 0$, we have a maximum or minimum, for the same restriction applies to the case in question, as to that which has been discussed in the Differential Calculus.

(430.) If, in the first place, we refer to the $\delta \int u$, the result of which is

$$\begin{aligned}
 \delta \int u &= (N - d P + d^2 Q - \&c.) \delta x + (n - d p + d^2 q - \&c.) \delta y \\
 &+ (P - d Q + \&c.) d \delta x + (p - d q + \&c.) d \delta y \\
 &+ \&c. \\
 &+ \int (M - d N + d^2 P - d^3 Q + \&c.) \delta x \\
 &+ \int (m - d n + d^2 p - d^3 q + \&c.) \delta y,
 \end{aligned}$$

we perceive that it is composed of two parts, entirely distinct from each other, one of which is affected with the integral sign, and the other free from it: and since, when $\int u$ is a maximum or minimum, $\delta \int u = 0$, and in the expression to which it is equal must also $= 0$; but as the part out of the integral sign involves the values of δx and δy at the limits only, while the part under the integral sign contains the general values of x and y , we must put these expressions separately equal to nothing.

If the limits be fixed, then $\delta x = 0$ and $\delta y = 0$.

$$\therefore M - d N + d^2 P - d^3 Q + \&c. = 0$$

$$m - d n + d^2 p - d^3 q + \&c. = 0.$$

from which equation the curve which has the required property may be determined.

(431.) But we proceed to examine the variation of $\int V d x$ when $\int V d x$ is a maximum or minimum, and from that expression we shall deduce some theorems which are eminently useful in the solution of the problems to which we shall afterwards refer.

(432.) We have seen that the variation of the $\int V d x$, when taken between the limits of x_1, y_1 , and x_2, y_2 , is expressed by

Calculus of
Variations.

$$\begin{aligned} \delta \int V dx &= V_2 \delta x_2 - V_1 \delta x_1 + \left(P_2 - \frac{d Q_2}{d x_2} + \&c. \right) w_2 \\ &\quad - \left(P_1 - \frac{d Q_1}{d x_1} + \&c. \right) w_1 \\ &\quad + \&c. \\ &\quad + \int \left(N - \frac{d P}{d x} + \frac{d^2 Q}{d x^2} - \frac{d^3 R}{d x^3} + \&c. \right) w dx; \end{aligned}$$

and since, when $\int V dx =$ a maximum or minimum, $\delta \int V dx = 0$, we must have at the same time the expansion $= 0$, and therefore the two parts of which it is composed each $= 0$. Hence we have two equations separately $= 0$, by one of which the variations at the extreme points may be determined, and by the other the nature of the function which possesses the maximum or minimum quality may be found.

Thus, by the equation $N - \frac{d P}{d x} + \frac{d^2 Q}{d x^2} - \&c. = 0$, combined with the equation $d V = M dx + N dy + P dp + \&c.$, may the curve be found, which is the object of our research, and by the equation $V_2 \delta x_2 - V_1 \delta x_1 + P_2 w_2 - P_1 w_1 + \&c. = 0$, may the position of its extreme points be determined, if these points be required.

(433.) But if, as it has been previously remarked, the extreme points be fixed $\delta x_1, \delta x_2, \&c.$ each $= 0$, and the latter equation is of no use.

The two equations may be illustrated by the consideration of the following problem, the solution of which will be first attempted. And, in the first place, had we to find the shortest line between two fixed points, we should

from the equation $N - \frac{d P}{d x} + \frac{d^2 Q}{d x^2} - \frac{d^3 R}{d x^3} + \&c. = 0$ determine the equation to the line: but as the extreme

points are fixed, and the line must pass through them, no other equation is necessary. But if it be required to draw the shortest line between two curves, then since, when drawn, the line must lie between two points, the former equation will give the same result as before, but the equation of the limits is now necessary to determine the precise points from which the shortest line of known species is now to be drawn, and from the equation to the limits which involve the variations of the extreme points, and from the equations to the given curves, may the conditions be found by which the line may be completely determined.

Thus, suppose PQ (fig. 2) to be one of the curves to be drawn between the given curves PP^1 and QQ^1 , and let P^1Q^1 be the curve which arises from making x and y respectively $x + \delta x$ and $y + \delta y$. Then, since P^1

and P are in the same curve PP^1 , and also Q and Q^1 in the same curve QQ^1 , if $\frac{dy}{dx} = m$, and $\frac{dy}{dx} = n$ be the equations

to the given curves: and y_1, x_1, y_2, x_2 be the coordinates of P and Q , the equations $\frac{\delta y_1}{\delta x_1} = m$ and $\frac{\delta y_2}{\delta x_2} = n$ will also be

true, for it is obvious that the ratio of the differentials of AN and PN will be the same as the ratio of the variations of the same quantities.

These values being substituted in the equation of limits, two of the quantities $\delta y_1, \delta y_2, \delta x_1, \delta x_2$, as δy_1 and δy_2 will be eliminated, and two independent variations, as δx_1 and δx_2 , will be left, the coefficients of which may be put $= 0$, and the conditions of the line at the points P and Q determined.

In this illustration it has been tacitly assumed that $\delta dy_1, \delta dx_1, \&c. = 0$, should they not $= 0$, the equations to the curves will give us relations by which some of these quantities may be eliminated, and then the coefficients of the remaining variations may be put equal to zero, and thus the equation of the limits satisfied.

In the succeeding pages we shall find instances illustrating these cases; sometimes the limits will be considered fixed, and at other times unknown, and to be determined by the nature of the problem.

(434.) But as the solution of problems of maxima and minima is much facilitated by deducing from the general expression some particular formulas, we proceed to investigate them.

In general,

$$dV = M dx + N dy + P dp + Q dq + R dr + \&c.,$$

and

$$N - \frac{dP}{dx} + \frac{d^2Q}{dx^2} - \frac{d^3R}{dx^3} + \&c. = 0.$$

1. Let all the coefficients, except N and P , $= 0$

$$\therefore dV = N dy + P dp, \text{ and } N - \frac{dP}{dx} = 0 \therefore N = \frac{dP}{dx}.$$

$$\therefore dV = dP \cdot \frac{dy}{dx} + P dp = p dP + P dp = d(Pp + c)$$

$$\therefore V = Pp + c.$$

2. Let all but M, N , and P , be equal to nothing;
then

$$dV = M dx + d(Pp + c)$$

$$\therefore V = \int M dx + Pp + c.$$

3. Let $M = 0, N = 0$, and all the coefficients after $Q = 0$.

Calculus of
Variations.

And

$$\therefore dV = P dp + Q dq.$$

$$\frac{dP}{dx} + \frac{d^2Q}{dx^2} = 0 \therefore dP = \frac{d^2Q}{dx^2} dx$$

$$\therefore P = \int \frac{d^2Q}{dx^2} = \frac{dQ}{dx} + C$$

$$\therefore dV = \frac{dp}{dx} dQ + Q dq + C dp = d(Qq + Cp + C_1)$$

$$\therefore V = Qq + Cp + C'_1.$$

If M also does not = 0, then $V = \int M dx + Qq + Cp + C'_1$.

The following Examples will illustrate the use of these formulas.

(435.) Problem 1. Find the shortest line between two given points. Here

$$\int V dx = \int dx \sqrt{1 + \frac{dy^2}{dx^2}} = \int dx \sqrt{1 + p^2}.$$

$$\therefore V = \sqrt{1 + p^2}.$$

$$\therefore dV = \frac{p}{\sqrt{1 + p^2}} dp = M dx + N dy + P dp + Q dq + \&c.$$

$$\therefore M = 0, N = 0, P = \frac{p}{\sqrt{1 + p^2}}, Q = 0, \&c. = \&c.$$

But

$$N - \frac{dP}{dx} + \&c. = 0 \therefore \frac{dP}{dx} = 0 \therefore P = c$$

$$\therefore \frac{p}{\sqrt{1 + p^2}} = c \therefore p = \frac{c}{\sqrt{1 - c^2}} = a.$$

And $y = ax + b$ the equation to a straight line, and the constants a, b , may be determined by its passing through the given points.

Problem 2. Find the curve of quickest descent from one given point to another given point, the points being in a vertical plane, and gravity the accelerating force.

Make the higher point the origin of coordinates, and let the axis of y be measured downwards.

Then since, by Mechanics, $\frac{ds}{dt} = \sqrt{2gy}$.

$$\therefore t = \int \frac{ds}{\sqrt{2gy}} = \frac{1}{\sqrt{2g}} \cdot \int \frac{dx \sqrt{1 + p^2}}{\sqrt{y}} = \frac{1}{\sqrt{2g}} \cdot \int V dx$$

$$\therefore V = \frac{\sqrt{1 + p^2}}{\sqrt{y}}.$$

$$\therefore dV = -\frac{1}{2} \cdot \frac{\sqrt{1 + p^2}}{y^{\frac{3}{2}}} dy + \frac{p}{\sqrt{y} \sqrt{1 + p^2}} dp = N dy + P dp$$

$$\therefore N = -\frac{\sqrt{1 + p^2}}{2y^{\frac{3}{2}}} \text{ and } P = \frac{p}{\sqrt{y} \sqrt{1 + p^2}}. M = 0, Q = 0.$$

But then

$$V = Pp + c$$

or

$$\frac{\sqrt{1 + p^2}}{\sqrt{y}} = \frac{p^2}{\sqrt{y} \sqrt{1 + p^2}} + c$$

$$\therefore \frac{\sqrt{1 + p^2}}{\sqrt{y}} - \frac{p^2}{\sqrt{y} \sqrt{1 + p^2}} = \frac{1}{\sqrt{y} \sqrt{1 + p^2}} = c = \frac{1}{\sqrt{2a}}$$

by substituting for c

$$\therefore \sqrt{\frac{2a}{y}} = \sqrt{1 + p^2} \therefore p^2 = \frac{2a - y}{y} \therefore p = \frac{\sqrt{2ay - y^2}}{y}$$

$$\therefore \frac{dx}{dy} = \frac{y}{\sqrt{2ay - y^2}} = \frac{-(a - y - a)}{\sqrt{2ay - y^2}} = \frac{a}{\sqrt{2ay - y^2}} - \frac{a - y}{\sqrt{2ay - y^2}}$$

whence

$$x = a V \sin^{-1} \frac{y}{2a} - \sqrt{2ay - y^2}$$

Calculus of the equation to a cycloid, of which the base is coincident with the axis of x , and the curve meets the base in the origin. This is the simplest form of the *Brachystochrone*. Part III.

Problem 3. Required the curve which, by revolution round its axis, shall generate the solid of least resistance.

Resistance

$$= \int \frac{y \cdot p^3}{1 + p^2} dx = \int V dx$$

$$\therefore V = \frac{y p^3}{1 + p^2}$$

$$\begin{aligned} \therefore dV &= \frac{p^3}{1 + p^2} dy + y \cdot \frac{3p^2 \overline{1 + p^2} - 2p^4}{(1 + p^2)^2} dp \\ &= \frac{p^3}{1 + p^2} dy + y \frac{3p^2 + p^4}{(1 + p^2)^2} dp = N dy + P dp \end{aligned}$$

$$\therefore N = \frac{p^3}{1 + p^2}, P = \frac{3p^2 + p^4}{(1 + p^2)^2} y, M = 0, Q = 0, \&c.$$

And since, in this case, $V = Pp + c$

$$\begin{aligned} \therefore \frac{p^3 y}{1 + p^2} &= \frac{3p^3 + p^5}{1 + p^2} y + c \\ \therefore p^3 y + p^5 y &= 3p^3 y + p^5 y + c(1 + p^2) \\ \therefore 2p^3 y + c \overline{1 + p^2} &= 0, \end{aligned}$$

or, writing $-a$ for c ,

$$y = \frac{a \overline{1 + p^2}}{2p^3} = \frac{a}{2p^3} + \frac{a}{p} + \frac{ap}{2} \quad (1)$$

Again, since

$$\frac{dy}{dx} = p \therefore dx = \frac{dy}{p}$$

But from equation (1) by differentiation we have

$$\begin{aligned} dy &= -\frac{3a}{2} \cdot \frac{dp}{p^4} - \frac{a dp}{p^2} + \frac{a}{2} \cdot dp \\ \therefore dx &= -\frac{3a}{2} \cdot \frac{dp}{p^5} - \frac{a dp}{p^3} + \frac{a}{2} \cdot \frac{dp}{p} \\ \therefore x &= \frac{3a}{8} \frac{1}{p^4} + \frac{a}{2p^2} + \frac{a}{2} \cdot \log(p) + b. \quad (2) \end{aligned}$$

And if p could be eliminated between the equations (1) and (2), the relation between y and x , or the equation to the generating curve, would be known.

Problem 4. Required the curve which, within its own arc, its evolute, and radius of curvature, shall contain the least area.

Let R = radius of curvature to any point P at a distance (s) from the origin measured along the curve.

Then, if A = area included between the arc, evolute, and radius,

$$\frac{dA}{dx} = \frac{R}{2} \frac{ds}{dx}$$

But

$$R = \frac{(1 + p^2)^{\frac{3}{2}}}{-q} \quad \text{and} \quad \frac{ds}{dx} = \sqrt{1 + p^2}$$

$$\therefore \frac{dA}{dx} = -\frac{(1 + p^2)^2}{q} \quad \text{and} \quad \therefore V = \frac{(1 + p^2)^2}{q}$$

$$\therefore dV = \frac{2(1 + p^2)p}{q} dp - \frac{(1 + p^2)^2}{q^2} dq \quad \therefore Q = -\frac{(1 + p^2)^2}{q^2}$$

And, as p and q are alone involved,

$$V = Qq + cp + c' \quad \therefore \frac{2(1 + p^2)^2}{q} = cp + c'$$

$$\therefore 2 \frac{dx}{dp} = \frac{cp + c_1}{(1 + p^2)^2}, \text{ but since } dx = \frac{ds}{\sqrt{1 + p^2}}$$

$$\therefore 2 \frac{ds}{dp} = \frac{cp + c_1}{(1 + p^2)^{\frac{3}{2}}} = \frac{cp}{1 + p^2} + \frac{c_1}{(1 + p^2)^{\frac{3}{2}}}$$

$$\therefore 2(s - c') = -\frac{c}{\sqrt{1+p^2}} + \frac{c_1 p}{\sqrt{1+p^2}} = c_1 \frac{dy}{ds} - \frac{c dx}{ds}.$$

$$\therefore (s - c')^2 = c_1 y - c x + c''.$$

We may get rid of the constant c'' by moving the origin along the axis of x , so that x becomes $x + \delta$, and making $-c\delta + c'' = 0$.

$$\therefore s - c' = \sqrt{c_1 y - c x}$$

or

$$s = c' + 2\sqrt{\beta y - a x} \text{ if } c' = 4\beta, \text{ and } c = 4a.$$

which is the same equation as that in Lacroix, but which is there obtained by a more laborious process: the curve is the cycloid, and if, as in Woodhouse's Isoperimetrical Problems, we make $a = 0$ and $c' = 0$, then

$s = 2\sqrt{\beta y}$, a well-known property of the common cycloid.

Problem 5. Find the shortest line that can be drawn between two curves whose equations are known.

Here

$$V = \sqrt{1+p^2}, \quad dV = \frac{p}{\sqrt{1+p^2}} dp \quad \therefore P = \frac{p}{\sqrt{1+p^2}}.$$

and we know from Problem 1 that the line is a straight one, and $p = c$.

Let $dy = m dx$ and $dy = n dx$ be the equations to the two curves, and let y_1, x_1 and y_2, x_2 be the coordinates of the points in which the shortest line intersects them.

Now, since δy_1 and δx_1 represent the variations of y_1 and x_1 , as we pass from one point to another consecutive one in the curve $\frac{dy}{dx} = m$, we shall have

$$\frac{dy_1}{dx_1} = \frac{\delta y_1}{\delta x_1}, \text{ and also } \frac{dy_2}{dx_2} = \frac{\delta y_2}{\delta x_2}.$$

But the equation to the limits is

$$V_2 \delta x_2 - V_1 \delta x_1 + P_2 \delta y_2 - P_1 \delta y_1 = 0.$$

From which we obtain, since the variations of the extreme points are independent of each other,

$$V_1 \delta x_1 + P_1 \delta y_1 = 0, \text{ and } V_2 \delta x_2 + P_2 \delta y_2 = 0;$$

or

$$V_1 \delta x_1 + P_1 \delta y_1 - P_1 p_1 \delta x_1 = 0 \quad (1)$$

and

$$V_2 \delta x_2 + P_2 \delta y_2 - P_2 p_2 \delta x_2 = 0 \quad (2)$$

From (1) we have

$$V_1 + P_1 m - P_1 p_1 = 0,$$

and, therefore,

$$m = p_1 - \frac{V_1}{P_1} = p_1 - \frac{1+p_1^2}{p_1} = -\frac{1}{p_1} = -\frac{1}{c}.$$

From (2) we have

$$V_2 + P_2 n - P_2 p_2 = 0$$

$$\therefore n = p_2 - \frac{V_2}{P_2} = p_2 - \frac{1+p_2^2}{p_2} = -\frac{1}{p_2} = -\frac{1}{c}.$$

$$\therefore 1 + cm = 0 \text{ and } 1 + cn = 0,$$

which equations show that the line must cut both curves at right angles.

And since the equation to a line passing through two given points is $y - y_1 = \frac{y_2 - y_1}{x_2 - x_1} (x - x_1)$, and in this case $c = \frac{y_2 - y_1}{x_2 - x_1}$; therefore, substituting for c , we shall have $1 + m \frac{y_2 - y_1}{x_2 - x_1} = 0$ and $1 + n \frac{y_2 - y_1}{x_2 - x_1} = 0$, and from these two equations, and those of the known curves, the values of y_1, x_1, y_2, x_2 may be found, and the line completely determined.

Problem 6. Find the curve of quickest descent from one given curve to another given curve

Here

$$V = \frac{\sqrt{1+p^2}}{\sqrt{y}}.$$

$$\therefore dV = -\frac{2\sqrt{1+p^2}}{y^{\frac{3}{2}}} dy + \frac{p}{\sqrt{y}\sqrt{1+p^2}} dp = N dy + P dp,$$

whence

$$M = 0 \quad N = -\frac{2\sqrt{1+p^2}}{y^{\frac{3}{2}}} \text{ and } P = \frac{p}{\sqrt{y}\sqrt{1+p^2}}, \text{ \&c.}$$

$$\therefore V = Pp + c;$$

and, as before,

Calculus of
Variations.

$$\frac{1}{\sqrt{y} \sqrt{1+p^2}} = c = \frac{1}{\sqrt{2a}} \dots \sqrt{y} \sqrt{1+p^2} = \sqrt{2a};$$

and the equations of the limits give

$$V_1 \delta x_1 + P_1 \delta y_1 - P_1 p_1 \delta x_1 = 0 \text{ and } V_2 \delta x_2 + P_2 \delta y_2 - P_2 p_2 \delta x_2 = 0.$$

But if $\frac{dy}{dx} = m$ and $\frac{dy}{dx} = n$ be the equations to the curves $\frac{\delta y_1}{\delta x_1} = m$ and $\frac{\delta y_2}{\delta x_2} = n$, whence

$$V_1 - P_1 p_1 + P_1 m = 0 \text{ and } V_2 - P_2 p_2 + P_2 n = 0.$$

But

$$\therefore V - Pp = c = \frac{1}{\sqrt{2a}} \dots = \frac{1}{\sqrt{y} \sqrt{1+p^2}}.$$

and

$$P = \frac{p}{\sqrt{y} \sqrt{1+p^2}} = \frac{p}{\sqrt{2a}}.$$

$$\therefore \frac{1}{\sqrt{2a}} + \frac{p_1 m}{\sqrt{2a}} = 0 \text{ and } \frac{1}{\sqrt{2a}} + \frac{p_2 n}{\sqrt{2a}} = 0$$

$$\therefore 1 + p_1 m = 0 \text{ and } 1 + p_2 n = 0.$$

The last two equations show that the cycloid cuts the two curves at right angles. Also from the equation $\sqrt{y} \sqrt{1+p^2} = \sqrt{2a}$, it appears that the base of the cycloid coincides with the horizontal line from which we have supposed the body to have fallen to acquire the velocity in the cycloid.

(436.) In the problems which have been hitherto solved, the function V does not involve the limits of the integral. There are, however, cases in which this does happen, as, for instance, when the brachystochrone is required between two curves, and the motion is to commence from one of the curves. In such case, which we considered when the general theorems were investigated, we must add to the equation of the limits the terms

$\delta x_1 \int \frac{dV}{dx_1} dx + \delta y_1 \int \frac{dV}{dy_1} dy + \&c.$, and we have the equation

$$\delta \int V dx = V_2 \delta x_2 - V_1 \delta x_1 + \delta x_1 \int \frac{dV}{dx_1} dx + \delta y_1 \int \frac{dV}{dy_1} dy + \&c.$$

$$+ P_2 w_2 - P_1 w_1 + \&c. + \int \left\{ N - \frac{dP}{dx} + \&c. \right\} w dx.$$

Example. Let the curve of quickest descent between two curves be required, the motion commencing at the first.

Here, if y_1 be the vertical coordinate of the point at which the motion commences, and y that of the body at the end of t'' ,

$$t = \frac{1}{\sqrt{2g}} \int \frac{\sqrt{1+p^2}}{\sqrt{y-y_1}} dx$$

$$\therefore V = \frac{\sqrt{1+p^2}}{\sqrt{y-y_1}}$$

$$\therefore dV = \frac{p}{\sqrt{y-y_1} \sqrt{1+p^2}} dp + \frac{\sqrt{1+p^2}}{2(y-y_1)^{\frac{3}{2}}} dy_1 - \frac{\sqrt{1+p^2}}{2(y-y_1)^{\frac{3}{2}}} dy.$$

whence

$$P = \frac{p}{\sqrt{y-y_1} \sqrt{1+p^2}}, \quad N = \frac{-\sqrt{1+p^2}}{2(y-y_1)^{\frac{3}{2}}}, \quad \frac{dV}{dy_1} = \frac{\sqrt{1+p^2}}{2(y-y_1)^{\frac{3}{2}}}$$

we may $\therefore$ use the formula $V = Pp + c$.

$$\therefore \frac{\sqrt{1+p^2}}{\sqrt{y-y_1}} = \frac{p^2}{\sqrt{y-y_1} \sqrt{1+p^2}} + c, \text{ or } \sqrt{y-y_1} \cdot \sqrt{1+p^2} = \frac{1}{c} = \sqrt{2a},$$

an equation to a cycloid, its cusp being at the point at which the motion begins.

Next, referring to the equation of limits, since V does not involve x_1, x_2 , &c., we have merely to find $\frac{dV}{dy_1}$.

But

$$\frac{dV}{dy_1} = \frac{\sqrt{1+p^2}}{2(y-y_1)^{\frac{3}{2}}} = N = -\frac{dP}{dx} \therefore N - \frac{dP}{dx} = 0$$

$$\therefore \int \frac{dV}{dy_1} dy = -P = P_1 - P_2,$$

when taken between the proper values. Hence the equation for the limits becomes

Calculus of
Variations. or

or

$$V_2 \delta x_2 - V_1 \delta x_1 + P_2 w_2 - P_1 w_1 + (P_1 - P_2) \delta y_1 = 0,$$

$$(V_2 - P_2 p_2) \delta x_2 - (V_1 - P_1 p_1) \delta x_1 + P_2 \delta y_2 - P_1 \delta y_1 = 0,$$

$$\frac{\delta x_2}{\sqrt{2a}} - \frac{\delta x_1}{\sqrt{2a}} + \frac{p_2}{\sqrt{2a}} \delta y_2 - \frac{p_1}{\sqrt{2a}} \delta y_1 = 0.$$

and $\therefore$ if $\frac{dy}{dx} = m$ and $\frac{dy}{dx} = n$ be the equations to the limiting curves $\therefore \frac{\delta y_1}{\delta x_1} = m$ and $\frac{\delta y_2}{\delta x_2} = n$. we have

$$(1 + p_2 n) \delta x_2 - (1 + p_1 m) \delta x_1 = 0.$$

whence δx_2 and δx_1 are totally independent of each other,

$$1 + p_2 n = 0 \text{ and } 1 + p_1 m = 0 \therefore m = n,$$

or the tangents at the points where the cycloid meets the curves are parallel, and, since $1 + p_2 n = 0$, it cuts the second curve at right angles.

(437.) The problems which have been the objects of our consideration in the preceding pages have been those of absolute maxima and minima. We proceed to treat of questions of relative maxima and minima. Of this kind is the problem, the length of a curve being given, find its species, that the area included by it may be a maximum. Such is the problem first proposed and solved by James Bernoulli, and to which the name of Isoperimetrical has been given, a name which is extended to all questions of this class.

The problem of relative maxima and minima in its most general point of view may be defined to be this. To find that relation between the variables y and x , that while $\int u_1 dx$ is constant, the $\int u dx$ may be a maximum or minimum. The solution of this question is obtained by multiplying $\int u_1 dx$ by a constant quantity (a), and adding the product to $\int u dx$, and then substituting their sum for $\int V dx$ in the preceding theorems; or, in other words, making the variation of $\int u dx + a \int u_1 dx$, or of $\int dx (u + a u_1) = 0$. and this will appear obvious if we consider that $\therefore \int u_1 dx = c$ and $\int u dx$ is a maximum or minimum; $\therefore \delta \int u_1 dx = 0$ and $\delta \int u dx = 0$, and as the condition of the greatest or least value of $\int u dx$ is dependent upon the equation $\int u_1 dx = c$, every condition of the problem will be included in the variation of $\int (u + a u_1) dx$.

(438.) To put this, however, in a more distinct point of view, the following proof, which is founded upon that given by Sir John Herschell, in a note to the translation of Lacroix's *Elementary Treatise on the Differential and Integral Calculus*, may be here introduced. And, first, we shall show that if there be any number of independent equations, $P = 0$, $Q = 0$, $R = 0$, &c., where P , Q , R , &c., are functions of x , y , p , q , &c., they may be all included in the general equation $P + Qa + Rb + \&c. = 0$, in which the quantities a , b , &c. are entirely independent of x , y , p , q , &c. For the sake of simplicity, let P , Q , and R , be alone taken; then $P + Qa + Rb = 0$ shall include the equations $P = 0$, $Q = 0$, $R = 0$.

For, since P , Q , R , remain unchanged while a , b , may alter, the following equations will hold good simultaneously.

$$P + Qa + Rb = 0$$

$$P + Qa_1 + Rb_1 = 0$$

$$P + Qa_2 + Rb_2 = 0$$

$$\therefore Qa - a_1 + Rb - b_1 = 0 \quad (1)$$

and

$$\therefore Qa - a_2 + Rb - b_2 = 0 \quad (2)$$

$$\therefore \text{from (2)} \quad Q = -R \frac{b - b_2}{a - a_2}.$$

$\therefore$ substituting this value for Q in equation (1).

$$R \cdot \left(\frac{b - b_2 \cdot a - a_1}{a - a_2} - b - b_1 \right) = 0$$

$$\text{i. e. } R (b - b_2 \cdot a - a_1 - b - b_1 \cdot a - a_2) = 0.$$

$$\text{i. e. } R (b a_2 + b_2 a_1 + b_1 a - b_1 a_2 - b a_1 - b_2 a) = 0$$

or

$$R \cdot f(a b a_1 b_1 a_2 b_2) = 0,$$

whence, since $f(a b a_1 b_1 a_2 b_2)$ does not necessarily $= 0$, $\therefore R = 0$. The general equation is now reduced to $P + Qa = 0$; also $\therefore P + Qa_1 = 0$ $\therefore$ by subtraction $Q(a - a_1) = 0$ and $a - a_1$ does not $= 0$. $\therefore Q = 0$ and $\therefore P = 0$. Hence the equation $P + aQ + bR = 0$ does include the equations $P = 0$, $Q = 0$, $R = 0$.

Now, to apply this reasoning to the case before us, let

$$P = \delta \int u dx, \quad Q = \delta \int u_1 dx, \quad R = \delta \int u_2 dx;$$

then will the equation $\delta \int (u + a u_1 + b u_2) dx = 0$ include the separate equations of $\delta \int u dx = 0$, $\delta \int u_1 dx = 0$; $\delta \int u_2 dx = 0$, if a and b be quantities entirely independent of x , y , p , q , &c.

Now, in the particular case of relative maxima and minima, if $\int u dx$ be a maximum or minimum, $\delta \int u dx = 0$, and if $\int u_1 dx$, taken between the same limits, be of a given value, $\delta \int u_1 dx = 0$. Hence every condition of the problem will be included under the equation

$$\delta \int (u + a u_1) dx = 0.$$

Calculus of
Variations.

It is plain that if $\int u_2 dx$ be also constant, we must make $\delta \int (u + au + bu_2) dx = 0$, and so on for any number of functions. Part III.

(439.) Hence, in the variation of $\int V dx$, we must merely write for V , $V + au$, or $V + au + bv$, &c., and proceed as in the cases of absolute maxima and minima. In these examples the total variation will be expressed by $\delta \int V_1 dx$.

(440.) Example 1. To find the curve which under a given perimeter includes the greatest area.

Here $\int u dx = \int \sqrt{1+p^2} dx$ is given, and $\int V dx = \int y dx$,

$$\therefore \int V_1 dx = \int (V + au) dx = \int (y + a\sqrt{1+p^2}) dx$$

$$\therefore V_1 = y + a\sqrt{1+p^2}$$

$$\therefore dV_1 = dy + \frac{ap}{\sqrt{1+p^2}} dp = M dx + N dy + P dp + \&c.$$

$$\therefore M = 0, N = 1, P = \frac{ap}{\sqrt{1+p^2}}, Q = 0,$$

and $\therefore$ from $N - \frac{dP}{dx} = 0$, and $dV = N dy + P dp$; we have

$$V_1 = Pp + c,$$

or

$$y + a\sqrt{1+p^2} = \frac{ap^2}{\sqrt{1+p^2}} + c$$

$$\therefore y - c = a \left\{ \frac{p^2}{\sqrt{1+p^2}} - \sqrt{1+p^2} \right\} = -\frac{a}{\sqrt{1+p^2}}.$$

$$\therefore 1+p^2 = \frac{a^2}{y-c}^2 \quad \therefore p^2 = \frac{a^2 - y - c}{y-c}^2.$$

$$\therefore \frac{dx}{dy} = \frac{y-c}{\sqrt{a^2 - y - c}}.$$

$$\therefore x - c_1 = -\sqrt{a^2 - y - c}.$$

$$\therefore (x - c_1)^2 + y - c = a^2,$$

the equation to a circle.

Example 2. Required the Brachystochrone, when the length of the curve is given.

Here

$$u = \sqrt{1+p^2} \text{ and } V = \frac{\sqrt{1+p^2}}{\sqrt{y}}.$$

$$\therefore V_1 = V + au = \frac{\sqrt{1+p^2}}{\sqrt{y}} + a\sqrt{1+p^2}.$$

$$\therefore dV_1 = \left(\frac{p}{\sqrt{y}\sqrt{1+p^2}} + \frac{ap}{\sqrt{1+p^2}} \right) dp - \frac{\sqrt{1+p^2}}{2y^{\frac{3}{2}}} dy = P dp + N dy$$

$$\therefore N = -\frac{\sqrt{1+p^2}}{2y^{\frac{3}{2}}} \quad P = \frac{p}{\sqrt{y}\sqrt{1+p^2}} + \frac{ap}{\sqrt{1+p^2}}.$$

But

$$V_1 = Pp + c$$

$$\therefore \frac{\sqrt{1+p^2}}{\sqrt{y}} + a\sqrt{1+p^2} = \frac{p^2(1+a\sqrt{y})}{\sqrt{y}\sqrt{1+p^2}} + c$$

$$\therefore \frac{1+p^2}{\sqrt{y}} \cdot (1+a\sqrt{y}) = \frac{p^2(1+a\sqrt{y})}{\sqrt{y}} + c\sqrt{1+p^2}$$

$$\therefore \frac{1+a\sqrt{y}}{\sqrt{y}} = c\sqrt{1+p^2}$$

$$\therefore p^2 = \frac{(1+a\sqrt{y})^2}{c^2 y} - 1 = \frac{1+2a\sqrt{y}+(a^2-c^2)y}{c^2 y}$$

$$\therefore \frac{dx}{dy} = \frac{c\sqrt{y}}{\sqrt{1+2a\sqrt{y}+(a^2-c^2)y}}$$

Calculus of which by putting z^2 for y may be easily integrated, and which will depend upon logarithms or circular arcs, Part III.
 Variations. according as a^2 is greater or less than c^2 .

Example 3. Find the equation to the curve, which, of all those that have the same length and include the same area, shall, by rotation round the axis of x , generate the greatest solid.

Here

$$\int V_1 dx = \int (u + au_1 + bu_2) dx$$

since

$$\text{solid} = \pi \int y^2 dx, \quad \text{length} = \int \sqrt{1+p^2} dx, \quad \text{and area} = \int y dx,$$

$$\therefore V_1 = u + au_1 + bu_2 = y^2 + a\sqrt{1+p^2} + by.$$

$$\therefore dV_1 = (2y + b) dy + \frac{ap}{\sqrt{1+p^2}} dp = N dy + P dp$$

$$\therefore N = 2y + b, \quad P = \frac{ap}{\sqrt{1+p^2}}, \quad M = 0, \quad Q = 0.$$

But, in this case,

$$V = Pp + c$$

$$\therefore y^2 + by + a\sqrt{1+p^2} = \frac{ap^2}{\sqrt{1+p^2}} + c$$

$$\therefore (y^2 + by)\sqrt{1+p^2} + a = c\sqrt{1+p^2}$$

$$\therefore \sqrt{1+p^2} = \frac{a}{c - (y^2 + by)}$$

$$p^2 = 1 - \frac{a^2}{[c - (y^2 + by)]^2} = \frac{(c - y^2 - by)^2 - a^2}{[c - (y^2 + by)]^2}$$

$$\therefore \frac{dx}{dy} = \frac{c - y^2 - by}{\sqrt{(c - y^2 - by)^2 - a^2}}.$$

Example 4. Given the length of a curve to find its form, that its centre of gravity may be the lowest possible

Here

$$\int V dx = \int (u + au_1) dx.$$

Let

$$X = \text{depth of centre of gravity, } \therefore X = \frac{\int x \sqrt{1+p^2} dx}{\int \sqrt{1+p^2} dx} \\ = \frac{\int x \sqrt{1+p^2} dx}{l} \text{ if } l = \text{length of curve}$$

$$\therefore V = \frac{x \sqrt{1+p^2}}{l} + a \sqrt{1+p^2}$$

$$dV = \frac{\sqrt{1+p^2}}{l} dx + \frac{px}{l \sqrt{1+p^2}} dp + \frac{ap}{\sqrt{1+p^2}} dp \\ = M dx + N dy + P dp + \&c.$$

$$\therefore M = \frac{\sqrt{1+p^2}}{l}, \quad N = 0, \quad P = \frac{px}{l \sqrt{1+p^2}} + \frac{ap}{\sqrt{1+p^2}}$$

But

$$N - \frac{dP}{dx} = 0 \therefore P = c.$$

$$\frac{p \cdot x + a}{l \sqrt{1+p^2}} = c$$

$$\frac{\sqrt{1+p^2}}{p} = \frac{x+a}{lc} = \frac{x+a}{b} \text{ if } b = lc$$

$$\frac{1}{p^2} = \frac{(x+a)^2 - b^2}{b^2}$$

$$\therefore p = \frac{b}{\sqrt{(x+a)^2 - b^2}}.$$

$$\therefore y = b \cdot \log(x+a + \sqrt{(x+a)^2 - b^2}) + c_1.$$

the equation to a catenary.

(441.) Find the curve B M, which is the least possible, when the area A B M N is given.

Here, (fig. 3.) area = $\int y dx$, length = $\int \sqrt{1+p^2} \cdot dx$

Calculus of
Variations.

$$\therefore V = \sqrt{1+p^2} + ay$$

$$dV = a dy + \frac{p dp}{\sqrt{1+p^2}} = N dy + P dp + \&c.$$

$$\therefore N = a, P = \frac{p}{\sqrt{1+p^2}}, Q = 0, R = 0, \&c.$$

Therefore, in this case,

$$V = Pp + c,$$

or

$$ay + \sqrt{1+p^2} = \frac{p^2}{\sqrt{1+p^2}} + c$$

$$\therefore ay \sqrt{1+p^2} + 1 = c \sqrt{1+p^2}.$$

and putting

$$a = \frac{1}{a} \text{ and } \beta = \frac{c}{a}, (\beta - y) \sqrt{1+p^2} = (a)$$

$$\therefore 1 + p^2 = \frac{a^2}{(\beta - y)^2} \text{ and } p^2 = \frac{a^2 - (\beta - y)^2}{(\beta - y)^2}$$

$$\therefore \frac{dx}{dy} = \frac{(\beta - y)}{\sqrt{a^2 - (\beta - y)^2}}.$$

whence

$$(x - c_1)^2 + (\beta - y)^2 = a^2.$$

the equation to a circle.

(442.) Find the same when the area included between two lines drawn from a given point, and including an angle, is given.

Here

$$s = \int \sqrt{1+p^2} \cdot dx, \text{ and area} = \frac{1}{2} \cdot \int (x dy - y dx).$$

$$\therefore V = \sqrt{1+p^2} + a \cdot (px - y).$$

$$\therefore dV = \frac{p dp}{\sqrt{1+p^2}} + a \cdot (p dx + x dp - dy) = \frac{p dp}{\sqrt{1+p^2}} + a x dp.$$

$$\therefore M = 0, N = 0, P = \frac{p}{\sqrt{1+p^2}} + ax, \text{ and } \frac{dP}{dx} = 0 \therefore P = c$$

$$\therefore \frac{p}{\sqrt{1+p^2}} = -ax + c = a \cdot \left(\frac{c}{a} - x \right) = \frac{a-x}{\beta} : \text{ if } a = \frac{1}{\beta} \text{ and } \frac{c}{a} = a$$

$$\frac{1}{p^2} = \frac{\beta^2}{(a-x)^2} - 1 = \frac{\beta^2 - (a-x)^2}{(a-x)^2}$$

$$\therefore \frac{dy}{dx} = \frac{a-x}{\sqrt{\beta^2 - (a-x)^2}}$$

whence

$$(y - c_1)^2 + (a - x)^2 = \beta^2,$$

the equation to a circle.

(443.) In the preceding problems we have only considered those cases in which the variable y is a function of x alone; we proceed to show the application of the formulæ to those questions in which a third variable z is introduced. The general expression for the variation of $\int V dx$, when y and z are functions of x , is

$$\begin{aligned} \delta \int V dx &= V \delta x + \left(P - \frac{dQ}{dx} + \frac{d^2R}{dx^2} - \&c. \right) w \\ &+ \left(P_1 - \frac{dQ_1}{dx} + \frac{d^2R_1}{dx^2} - \&c. \right) w_1 \\ &+ \&c. + \&c. + \&c. \\ &+ \int \left(N - \frac{dP}{dx} + \frac{d^2Q}{dx^2} - \frac{d^3R}{dx^3} + \&c. \right) w dx \\ &+ \int \left(N_1 - \frac{dP_1}{dx} + \frac{d^2Q_1}{dx^2} - \frac{d^3R_1}{dx^3} + \&c. \right) w_1 dx. \end{aligned}$$

in which $w_1, N_1, P_1, Q_1, R_1, \&c.$, are of the same form as $w, N, P, Q, R, \&c.$, but z is to be written instead of y .

Calculus of Variations.

Example. Required the shortest distance between two points in space.

Part III.

 Here, if s be the distance, $s = \int \sqrt{1 + \frac{dy^2}{dx^2} + \frac{dz^2}{dx^2}} \cdot dx$;

$$\therefore V = \sqrt{1 + \frac{dy^2}{dx^2} + \frac{dz^2}{dx^2}} = \sqrt{1 + p^2 + p_1^2}$$

$$\therefore dV = \frac{p dp}{\sqrt{1 + p^2 + p_1^2}} + \frac{p_1 dp_1}{\sqrt{1 + p^2 + p_1^2}}$$

But, at a maximum or minimum,

$$N - \frac{dP}{dx} + \frac{d^2Q}{dx^2} - \frac{d^3R}{dx^3} + \&c. = 0 \quad (1)$$

and

$$N_1 - \frac{dP_1}{dx} + \frac{d^2Q_1}{dx^2} - \frac{d^3R_1}{dx^3} + \&c. = 0 \quad (2);$$

 whence $\therefore N = 0, Q = 0, R = 0, \&c.$, and $N_1 = 0, Q_1 = 0, R_1 = 0, \&c.$, we have from equations (1) and (2)

$$\frac{dP}{dx} = 0 \text{ and } \frac{dP_1}{dx} = 0, \therefore P = a \text{ and } P_1 = b.$$

But

$$P = \frac{p}{\sqrt{1 + p^2 + p_1^2}} \text{ and } P_1 = \frac{p_1}{\sqrt{1 + p^2 + p_1^2}}$$

$$\therefore \frac{dy}{dx} = a \sqrt{1 + p^2 + p_1^2} \text{ and } \frac{dz}{dx} = b \sqrt{1 + p^2 + p_1^2}$$

$$\therefore \frac{dy}{dz} = \frac{\frac{dy}{dx}}{\frac{dz}{dx}} = \frac{a}{b} \text{ and } \therefore y = \frac{a}{b} z + c.$$

 Whence it appears that the trace of the required distance upon the plane of yz is a straight line; and as, if we had assumed z to be the independent variable, the result would have been similar, *i. e.* of the form $y = \frac{a_1}{b_1} x + c_1$,

we may conclude that the curve line joining the two points lies in one plane, or is a curve of simple curvature.

Hence if the points be given and fixed, and there be no other condition than that simply of shortest distance between them, the case becomes that of the first example, and the line is a straight one, the nature of which may be determined by the given coordinates of the points to which it must be drawn.

(444.) The problem, however, may be solved by the following more general process, and which illustrates the methods given in articles (421 and 422.)

 Thus, supposing $\int ds = \int \sqrt{dx^2 + dy^2 + dz^2}$,

$$\begin{aligned} \therefore \delta \int ds &= \int \delta ds = \int \frac{dx}{ds} \delta dx + \int \frac{dy}{ds} \delta dy + \int \frac{dz}{ds} \delta dz \\ &= \frac{dx}{ds} \delta x + \frac{dy}{ds} \delta y + \frac{dz}{ds} \delta z - \int \left\{ d \frac{dx}{ds} \cdot \delta x + d \frac{dy}{ds} \cdot \delta y + d \frac{dz}{ds} \delta z \right\} \end{aligned}$$

 Now by reference to article (422.), we find $M = 0, m = 0, \mu = 0$,

$$N = \frac{dx}{ds}, n = \frac{dy}{ds}, \nu = \frac{dz}{ds}, \therefore dN = 0, dn = 0, d\nu = 0,$$

$$\therefore d \cdot \frac{dx}{ds} = 0, d \cdot \frac{dy}{ds} = 0, \text{ and } d \cdot \frac{dz}{ds} = 0,$$

$$\therefore \frac{dx}{ds} = a, \frac{dy}{ds} = b, \frac{dz}{ds} = c;$$

whence

$$\frac{dx^2}{ds^2} + \frac{dy^2}{ds^2} + \frac{dz^2}{ds^2} = 1 = a^2 + b^2 + c^2$$

 an equation of condition by which the constants a, b, c are connected. Also, since

$$\frac{dx}{dz} = \frac{a}{c} \text{ and } \frac{dy}{dz} = \frac{b}{c},$$

$$\therefore x = \frac{a}{c} z + c_1 (1) \text{ and } y = \frac{b}{c} z + c_2 (2),$$

the equations to a straight line.

Calculus of Variations. The five constants a, b, c, c_1, c_2 may be found from the four equations which arise from the substitution of the given coordinates of the points for x, y, z , in equations (1) and (2), and from the equation of condition $a^2 + b^2 + c^2 = 1$. Part III.

If one of the points be fixed, but the other situated on a curve surface, let $dz = p dx + q dy$ be the equation to the surface. Then, if the coordinates of the second point be x_2, y_2, z_2 ,

$$\delta z_2 = p_2 \delta x_2 + q_2 \delta y_2,$$

and the equation of the limits, which is

$$\frac{dx_2}{ds_2} \delta x_2 + \frac{dy_2}{ds_2} \delta y_2 + \frac{dz_2}{ds_2} \delta z_2 = 0$$

becomes

$$dx_2 \delta x_2 + dy_2 \delta y_2 + dz_2 \cdot (p_2 \delta x_2 + q_2 \delta y_2) = 0,$$

or

$$(dx_2 + p_2 dz_2) \delta x_2 + (dy_2 + q_2 dz_2) \delta y_2 = 0;$$

and since δx_2 and δy_2 are independent variations, we must put their coefficients separately equal to zero.

$$\therefore dx_2 + p_2 dz_2 = 0 \text{ and } dy_2 + q_2 dz_2 = 0,$$

which show that the required line coincides with the normal of the given surface.

(445.) Next; let it be required to draw the shortest line upon a given surface.

In this case the variations of the coordinates x, y, z , which are under the sign $\int$, must satisfy the differential equation to the surface, since the line in question coincides at every point with it.

Let $\therefore dz = p dx + q dy$ be the equation to the surface, whence we have $\delta z = p \delta x + q \delta y$; and substituting for δz , we have

$$\begin{aligned} \delta \cdot \int ds &= \left(\frac{dx}{ds} + p \frac{dz}{ds} \right) \delta x + \left(\frac{dy}{ds} + q \frac{dz}{ds} \right) \delta y \\ &\quad - \int \left\{ \left(d \cdot \frac{dx}{ds} + p \cdot d \cdot \frac{dz}{ds} \right) \delta x + \left(d \cdot \frac{dy}{ds} + q \cdot d \cdot \frac{dz}{ds} \right) \delta y \right\}; \end{aligned}$$

whence we have from the part under the sign of integration

$$d \cdot \frac{dx}{ds} + p \cdot d \cdot \frac{dz}{ds} = 0 \text{ and } d \cdot \frac{dy}{ds} + q \cdot d \cdot \frac{dz}{ds} = 0,$$

which are the equations of the curve required.

Take for an example the least distance measured along a sphere.

Here

$$z^2 = r^2 - x^2 - y^2;$$

$$\therefore \frac{dz}{dx} = p = -\frac{x}{z} \text{ and } \frac{dz}{dy} = q = -\frac{y}{z},$$

and the equations become, considering ds constant,

$$z d^2 x - x d^2 z = 0 \text{ and } z d^2 y - y d^2 z = 0,$$

from which we also obtain

$$y d^2 x - x d^2 y = 0;$$

whence, by integration,

$$z dx - x dz = a_1 ds \quad (1)$$

$$y dz - z dy = a_2 ds \quad (2)$$

$$x dy - y dx = a_3 ds \quad (3).$$

Multiply (1) by y , (2) by x , and (3) by z , and add; and then

$$a_1 y + a_2 x + a_3 z = 0,$$

the equation to a plane which passes through the centre of the sphere; but the intersection of a plane with a sphere is a circle, and if the plane pass through the centre of the sphere it is a great circle; the required line is, therefore, a portion of a great circle of the sphere.

CALCULUS OF FINITE DIFFERENCES.

Calculus of
Finite
Differences.

(1.) Custom has decided that no Treatise on the Differential Calculus can be reckoned complete, unless it also include the Calculus of Finite Differences: and we adhere to the arrangement which has been made. Indeed we may consider that, by the term Differential Calculus, there is meant that branch of pure Mathematics which solely treats of variable quantities; and this division being allowed, the Calculus of Finite Differences is naturally a subdivision, and rightly occupies the place assigned to it.

Calculus of
Finite
Differences.

The intimate connection between it and the Differential Calculus, properly so called, will soon be seen; and in many instances it may be shown that the formulas of the one can be derived from processes given in the other.

The Calculus of Finite Differences, or of Differences, as Lacroix has proposed to name this branch of Mathematics, may, perhaps, be defined as that which chiefly treats of numbers, and of the change which numerical equations undergo, in consequence of given alterations taking place in the values of the number or numbers of which these are the functions.

Although this statement may at first lead the student to suppose that this Calculus is confined in its views, and limited in its applications, yet will he ultimately find its uses are most extensive: and, as instances, may be informed that the theorems which it demonstrates afford the means and frequently the only means of solution of the interesting Problems to which we are led in our inquiries respecting the Summation of Series, and the questions arising from the Theory of Probabilities, and the construction of Logarithmic Tables.

(2.) We next proceed to explain the terms and the notation made use of in this branch of the Calculus.

If we take the series which is formed by the sum of the squares of the natural numbers, *viz.*

$$1^2 + 2^2 + 3^2 + 4^2 + 5^2 + \&c. + x^2 + \&c.$$

where x expresses the number of terms, and x^2 is in this case the x th term of the series. It is evident that by giving to x the values 1, 2, 3, &c., the 1st, 2d, 3d, &c. term is produced: on this account x^2 is called the general term of this series; and when the general term is known, the successive terms of the series are also capable of being found.

The general term is therefore a function of x , *i.e.* a function of its place in the series, and mathematicians have, for the most part, agreed to express this particular kind of function by the symbol u_x or v_x : the letter x is called the index, since it marks the place in the series to which any particular term belongs.

And, as in the Differential Calculus, when the form of $f(x)$ is given, that of $f(x+h)$ can be found by means of the differential coefficients of $f(x)$: so also may u_x , as will be shown, be found in terms of the differences of its preceding values.

The nature of these differences may be thus explained. But instead of the series of the squares let us take the following,

$$a + b + c + d + e + \&c.$$

where a, b, c , &c., are numbers connected together by some constant law of derivation, a condition implied by the notion of a series.

If now we subtract a from b , b from c , c from d , &c., we have the results

$$b - a, c - b, d - c, e - d, \&c.,$$

which are called first differences, $b - a$ being the first difference of a ; if the process be continued, we shall have

$$c - 2b + a, d - 2c + b, e - 2d + c, \&c.$$

which are termed second differences; and continuing the process we shall arrive at third, fourth, &c. differences.

(3.) Now if we return to the series of the squares of the natural numbers and write them down according to their actual values, and not symbolically, *viz.*

$$1 + 4 + 9 + 16 + 25 + 36 + 49 + \&c.$$

and if we subtract the first number from the second, the second from the third, the third from the fourth, &c., and afterwards again subtract the first of these differences from the second difference, the second from the third, and so on, we shall have, first writing down the original series, the series of numbers

$$\begin{array}{ll} 1 + 4 + 9 + 16 + 25 + 36 + 49 + \&c. & \text{squares,} \\ 3 + 5 + 7 + 9 + 11 + 13 + \&c. & \text{first differences,} \\ 2 + 2 + 2 + 2 + 2 + \&c. & \text{second differences;} \end{array}$$

whence it appears that the first differences are the odd numbers, and that the second differences are all equal.

Now the use of this investigation is this, that we can by mere addition produce any terms of the series we may wish, if we know three corresponding numbers in each of the three horizontal lines. Thus having given 16, 9, 2, to form the succeeding terms of the series, add 2 to 9 and 9 to 16, and we obtain 11 and 25, the next terms in the second and first lines; and these being found, we may form in a similar manner other terms. In fact, having given the 1, 3, 2, the first numbers of each horizontal line, 2 being assumed constant or the same for every place of the lowest line, all the other terms may be found. Then adding 2 to 3 we have 5, the second number in the middle line, and adding 3 to 1 we have 4, the second figure in the highest line. Again beginning from the constant difference 2, add 2 to 5 and we have 7, add 5 to 4 and we have 9, the next two figures, and similarly may all the terms be found.

Calculus of
Finite
Differences.

(4.) Had we taken the series of the cubes of the natural numbers, or $1 + 8 + 27 + 64 + 125 + 216 + 343 + \&c.$, and taken the first, second, and third differences, the first numbers of the horizontal lines, including the series itself, would be 1, 7, 12, 6, the third difference 6 is constant, and the process indicated in the preceding article would be found to have place here.

Calculus of
Finite
Differences.

And thus if the n th differences between successive logarithms become constant or very nearly so, the logarithms themselves may be found by successive additions only.

The truth of this rule will be afterwards proved, although the formation of the differences makes it almost sufficiently evident.

The term difference which we have used requires a particular definition, and it is understood to express the excess of one term over that which immediately precedes it. The first object of the Direct Calculus of Differences is to find the value of this difference whatever be the function of x ; and we may here add that x is supposed to increase by unity.

(5.) From this definition it appears that the difference of any function is found by writing $x + 1$, for x in it, and subtracting from the result the original function.

This operation is symbolically represented by prefixing the letter Δ before the function under consideration.

Thus Δu_x expresses the difference of u_x , and Δx the difference of x , and thus

$$u_{x+1} - u_x = \Delta u_x \text{ and } x + 1 - x = \Delta x.$$

(6.) But since $u_{x+1} - u_x$ or Δu_x may also be a function of x , and therefore susceptible of change when $x + 1$ is put for x in it: Δu_x will have a difference which is called the second difference of u_x .

And the second difference of Δu_x is from our definition

$$\Delta u_{x+1} - \Delta u_x = \Delta(u_{x+1} - u_x) = \Delta(\Delta u_x) = \Delta^2 u_x.$$

$\Delta^2 u_x$ being the symbol used for the second difference of u_x .

We may stop to remark that the equations

$$u_{x+1} = u_x + \Delta u_x \text{ and } \Delta u_{x+1} = \Delta^2 u_x + \Delta u_x$$

express the method used in determining the places of the numbers in the illustration given at the commencement of the article: thus let $x = 4$,

$$\therefore u_x = 16, \Delta u_x = 9, \Delta^2 u_x = 2, u_{x+1} = u_5 = 16 + 9 = 25 \text{ and } \Delta u_5 = 9 + 2 = 11.$$

(7.) The second difference being written $\Delta^2 u_x$, the third difference is expressed by $\Delta^3 u_x$, the fourth by $\Delta^4 u_x$, and the n th by $\Delta^n u_x$; a system of notation which bears a close analogy to that used in the early part of the Differential Calculus, when we had occasion to find the successive differential coefficients of a function.

(8.) Again referring to the definition of a difference, if $u_0, u_1, u_2, u_3, \&c., u_n$ be the values of u_x when 0, 1, 2, 3, &c. . . . n are put for x , we have the following equations:

$$u_1 - u_0 = \Delta u_0$$

$$u_2 - u_1 = \Delta u_1$$

$$u_3 - u_2 = \Delta u_2$$

$$u_4 - u_3 = \Delta u_3$$

$$\&c. = \&c.$$

$$u_n - u_{n-1} = \Delta u_{n-1},$$

whence by addition we obtain the theorem

$$u_n - u_0 = \Delta u_0 + \Delta u_1 + \Delta u_2 + \Delta u_3 + \&c. + \Delta u_{n-1}$$

Then taking the series $1 + 8 + 27 + 64 + 125 + 216 + \&c.$

$$u_0 = 1, \Delta u_0 = 7, \Delta u_1 = 19, \Delta u_2 = 37, \Delta u_3 = 61$$

$$u_4 - u_0 = \Delta u_0 + \Delta u_1 + \Delta u_2 + \Delta u_3 = 7 + 19 + 37 + 61 = 124,$$

$$\text{or } u_4 = 1 + 124 = 125, \text{ as in the series.}$$

In the same manner, since

$$\Delta u_1 - \Delta u_0 = \Delta(\Delta u_0) = \Delta^2 u_0$$

$$\Delta u_2 - \Delta u_1 = \Delta^2 u_1$$

$$\Delta u_3 - \Delta u_2 = \Delta^2 u_2$$

$$\&c. = \&c.$$

$$\Delta u_n - \Delta u_{n-1} = \Delta^2 u_{n-1}$$

$$\Delta u_n - \Delta u_0 = \Delta^2 u_0 + \Delta^2 u_1 + \Delta^2 u_2 + \&c. + \Delta^2 u_{n-1}.$$

(9.) From the notation which has been used in the preceding articles, we see that the difference of a function is expressed by prefixing the letter Δ ; what has been shown with regard to a monomial is also true for a set of terms connected by the sign $+$ or $-$.

Thus

$$\Delta(u_x + v_x - w_x) = u_{x+1} + v_{x+1} - w_{x+1} - (u_x + v_x - w_x) = u_{x+1} - u_x + v_{x+1} - v_x - w_{x+1} + w_x = \Delta u_x + \Delta v_x - \Delta w_x$$

or the difference of the sum of any number of functions is equal to the sum of the differences of each.

Also since

$$\Delta(a \cdot u_x) = a u_{x+1} - a u_x = a(u_{x+1} - u_x) = a \Delta u_x,$$

it appears that constant quantities may be brought without the sign of the difference.

Calculus of
Finite
Differences.

And since

$$\Delta(u_x \pm c) = \overline{u_{x+1} \pm c} - \overline{u_x \pm c} = u_{x+1} - u_x = \Delta u_x,$$

constant quantities connected to the function by the sign $\pm$ disappear when the difference of the function is taken.

 Calculus of
Finite
Differences.

The constant c need not, however, be independent of x , but must be such a function of it that $c_{x+1} = c_x$.

(10.) When the form of u_x is given, the first and successive differences are easily found, as the following illustrations will show.

Let $u_x = x^2$, or let u_x represent the general term of the series $1 + 4 + 9 + 16 + \&c.$, which is the sum of the squares of the natural numbers, a series to which we have frequently referred.

Then

$$u_{x+1} - u_x = \Delta u_x = (x+1)^2 - x^2 = 2x + 1$$

$$\Delta^2 u_x = 2(x+1) + 1 - (2x+1) = 2. \Delta^3 u_x = 0.$$

Again, if

$$u_x = x^3; \Delta u_x = (x+1)^3 - x^3 = 3x^2 + 3x + 1$$

$$\Delta^2 u_x = 3(2x+1) + 3 = 6x + 6. \Delta^3 u_x = 6, \Delta^4 u_x = 0;$$

this last expression may be thus verified, for $u_x = x^3$ represents the general term of the series $1 + 8 + 27 + 64 + 125 + \&c.$

The first differences of the terms are 7, 19, 37, 61, &c., the second are 12, 18, 24, &c., the third 6, 6, &c., and the 4th differences vanish.

(11.) Again, if $u_x = x^m \therefore \Delta u_x = (x+1)^m - x^m$

$$= m x^{m-1} + m \frac{m-1}{2} x^{m-2} + \frac{m(m-1)(m-2)}{1 \cdot 2 \cdot 3} x^{m-3} + \&c.$$

$$= m x^{m-1} + a x^{m-2} + b x^{m-3} + \&c.$$

$$\Delta^2 u_x = m \Delta x^{m-1} + a \Delta x^{m-2} + b \Delta x^{m-3} + \&c.$$

and by writing $m-1, m-2, m-3, \&c.$ for m in the expression for Δx^m , we shall find the value of $\Delta x^{m-1}, \Delta x^{m-2}, \Delta x^{m-3}, \&c.$, and we shall obtain

$$\Delta^2 u_x = m(m-1) x^{m-2} + a_1 x^{m-3} + b_1 x^{m-4} + \&c.$$

Similarly,

$$\Delta^3 u_x = m(m-1)(m-2) x^{m-3} + a_2 x^{m-4} + b_2 x^{m-5} + \&c.$$

and thus proceeding we shall obviously have

$$\Delta^n x^m = m(m-1)(m-2) \dots (m-n+1) x^{m-n} + A x^{m-n-1} + \&c.$$

and if $m = n$, every term but the first will vanish, and we shall finally have

$$\Delta^m x^m = m(m-1)(m-2) \dots (m-3) \dots 3 \cdot 2 \cdot 1,$$

a constant quantity, and, therefore, the higher differences of x^m will vanish.

(12.) Again, if $u_x = A x^m + B x^p + C x^q + \&c. \dots$ where m is the greatest index, then

$$\Delta^m u_x = A \Delta^m x^m + B \Delta^m x^p + C \Delta^m x^q + \&c.$$

But by the preceding article $\Delta^m x^m = m(m-1)(m-2) \dots 3 \cdot 2 \cdot 1$

$$\Delta^m x^p = 0, \Delta^m x^q = 0 \&c.$$

$$\therefore \Delta^m u_x = A m(m-1)(m-2) \dots 3 \cdot 2 \cdot 1.$$

(13.) The following examples contain some useful results, and will entirely explain the process of finding the differences of functions.

Example (1.) Let $u_x = a + bx$, which is the expression for the general term of an arithmetic series, u_0 being the first term.

$$\therefore u_{x+1} = a + b(x+1)$$

and

$$u_{x+1} - u_x = \Delta u_x = (a + b(x+1)) - (a + bx) = b$$

$$\Delta^2 u_x = 0, \text{ results which the formation of arithmetic series fully explains.}$$

Example (2.) Let

$$u_x = a^x \therefore \Delta u_x = a^{x+1} - a^x = (a-1)a^x.$$

$$\therefore \Delta^2 u_x = \Delta a - 1 a^x = a - 1 \Delta a^x = (a-1)^2 \cdot a^x$$

$$\Delta^3 u_x = (a-1)^3 \cdot a^x \text{ and } \therefore \Delta^n u_x = (a-1)^n \cdot a^x.$$

Example (3.) Let

$$u_x = \sin x\theta, \therefore \Delta u_x = \sin x\theta + 1\theta - \sin x\theta$$

$$= 2 \sin \frac{\theta}{2} \cdot \cos \left(x + \frac{1}{2}\right)\theta$$

Since

$$\sin A - \sin B = 2 \sin \frac{A-B}{2} \cdot \cos \frac{A+B}{2}.$$

Again, let

$$u_x = \cos x\theta, \therefore \Delta \cdot \cos x\theta = \cos x\theta + 1\theta - \cos x\theta$$

$$= -2 \sin \frac{\theta}{2} \cdot \sin \left(x + \frac{1}{2}\right)\theta.$$

Since

$$\cos A - \cos B = -2 \sin \frac{A-B}{2} \cdot \sin \frac{A+B}{2}$$

$$\begin{aligned}\Delta^2 \sin x \theta &= 2 \sin \frac{\theta}{2} \cdot \Delta \cdot \cos \left(x + \frac{1}{2} \right) \theta \\ &= 2 \sin \frac{\theta}{2} \cdot \left\{ \cos \left(x + \frac{3}{2} \right) \theta - \cos \left(x + \frac{1}{2} \right) \theta \right\} \\ &= -4 \sin^2 \frac{\theta}{2} \cdot \sin (x + 1) \theta.\end{aligned}$$

$$\begin{aligned}\therefore \Delta^3 \sin x \theta &= -4 \sin^2 \frac{\theta}{2} \cdot 2 \sin \frac{\theta}{2} \cdot \cos \left(x + 1 + \frac{1}{2} \right) \theta \\ &= -8 \sin^3 \frac{\theta}{2} \cdot \cos \left(x + \frac{3}{2} \right) \theta\end{aligned}$$

$$\therefore \Delta^4 \sin x \theta = 2^4 \sin^4 \frac{\theta}{2} \cdot \sin (x + 2) \theta$$

Similarly,

$$\Delta^4 \cdot \cos x \theta = 2^4 \sin^4 \frac{\theta}{2} \cdot \cos (x + 2) \theta.$$

Hence

$$\Delta^{2n} \sin x \theta = \pm \left(2 \sin \frac{\theta}{2} \right)^{2n} \cdot \sin (x + n) \theta$$

$$\Delta^{2n} \cos x \theta = \pm \left(2 \sin \frac{\theta}{2} \right)^{2n} \cdot \cos (x + n) \theta$$

the upper sign to be used when n is of the form $4m$, and the lower when it is of the form $4m + 2$,

and also $\Delta^{2n+1} \sin x \theta = \pm \left(2 \sin \frac{\theta}{2} \right)^{2n+1} \cos \left(x + n + \frac{1}{2} \right) \theta.$

Example (4.) Let

$$u_x = \tan x \theta$$

$$\Delta \tan x \theta = \tan \overline{x+1} \theta - \tan x \theta$$

$$= \frac{\sin \overline{x+1} \theta}{\cos \overline{x+1} \theta} - \frac{\sin x \theta}{\cos x \theta}$$

$$= \frac{\sin \overline{x+1} \theta \cdot \cos x \theta - \sin x \theta \cdot \cos \overline{x+1} \theta}{\cos x \theta \cdot \cos \overline{x+1} \theta} = \frac{\sin \theta}{\cos x \theta \cdot \cos \overline{x+1} \theta}$$

Similarly,

$$\Delta \cotan x \theta = \frac{-\sin \theta}{\sin x \theta \cdot \sin \overline{x+1} \theta}$$

Example (5.) $u_x = \log x$, $\therefore \Delta \log x = \log (x + 1) - \log x$

and $\Delta^2 \log x = \log \overline{x+2} - \log \overline{x+1} - (\log \overline{x+1} - \log x) = \log \overline{x+2} - 2 \log \overline{x+1} + \log x$

$$\Delta^3 \log x = \log \overline{x+3} - 3 \log \overline{x+2} + 3 \log \overline{x+1} - \log x$$

$$\Delta^4 \log x = \log \overline{x+4} - 4 \log \overline{x+3} + 6 \log \overline{x+2} - 4 \log \overline{x+1} + \log x,$$

and similarly it would appear that

$$\begin{aligned}\Delta^n \cdot \log x &= \log (x + n) - n \cdot \log (x + n - 1) + n \cdot \frac{n-1}{2} \log (x + n - 2) \\ &\quad - \frac{n \cdot n-1 \cdot n-2}{1 \cdot 2 \cdot 3} \log (x + n - 3) + \&c. \dots \pm \log x,\end{aligned}$$

a formula which will be shown hereafter to be true for every value of u_x .

(14.) Having found the difference of single terms, we proceed to deduce general expressions for the product and quotient of two or more functions.

Thus

$$\begin{aligned}\Delta (u_x v_x) &= u_{x+1} v_{x+1} - u_x v_x \\ &= (u_x + \Delta u_x) (v_x + \Delta v_x) - u_x v_x \\ &= u_x \Delta v_x + v_x \Delta u_x + \Delta u_x \Delta v_x \\ &= u_x \Delta v_x + v_{x+1} \Delta u_x,\end{aligned}$$

a formula of considerable utility in the inverse method of differences.

Again, $\Delta \left(\frac{u_x}{v_x} \right) = \frac{u_{x+1}}{v_{x+1}} - \frac{u_x}{v_x} = \frac{u_x + \Delta u_x}{v_x + \Delta v_x} - \frac{u_x}{v_x} = \frac{v_x \Delta u_x - u_x \Delta v_x}{v_{x+1} v_x}.$

Thus $\Delta (x^m \cdot a_x) = x^m \cdot \Delta a_x + a_{x+1} \cdot \Delta x^m = a_x \cdot \{ a - 1 x^m + a \Delta x^m \}$

and

$$\Delta \frac{x^m}{a_x} = \frac{x^m \cdot \Delta a_x - a_x \Delta x^m}{a_{x+1} \cdot a_x} = \frac{x^m \cdot (a - 1) - \Delta x^m}{a_{x+1}}.$$

Calculus of
Finite
Differences.

 (15.) Next to find the difference of the product of any number of functions $u_x \cdot u_{x+1} \cdot u_{x+2} \dots u_{x+n}$.

 Calculus of
Finite
Differences.

$$\Delta(u_x \cdot u_{x+1} \cdot u_{x+2} \dots u_{x+n}) = u_{x+1} u_{x+2} u_{x+3} \dots u_{x+n} \{u_{x+n+1} - u_x\}$$

and

$$\Delta \left(\frac{1}{u_x \cdot u_{x+1} \cdot u_{x+2} \dots u_{x+n}} \right) = \frac{1}{u_{x+1} \cdot u_{x+2} \dots u_{x+n}} \left\{ \frac{1}{u_{x+n+1}} - \frac{1}{u_x} \right\} = - \frac{u_{x+n+1} - u_x}{u_x \cdot u_{x+1} \cdot u_{x+2} \dots u_{x+n+1}}$$

 (16.) If $u_x = a + bx$, i. e. if u_x be the general term of an arithmetic series, these latter expressions assume a simple form to which we shall hereafter refer.

For then

$$u_{x+n+1} - u_x = (a + b \cdot x + n + 1) - (a + bx) = b \cdot n + 1.$$

$$\therefore \Delta(u_x \cdot u_{x+1} u_{x+2} \dots u_{x+n}) = n + 1 \cdot b \cdot \{u_{x+1} u_{x+2} \dots u_{x+n}\}$$

and

$$\Delta \left(\frac{1}{u_x \cdot u_{x+1} \dots u_{x+n}} \right) = \frac{-n + 1 \cdot b}{u_x u_{x+1} \dots u_{x+n+1}}.$$

Hence when the function is composed of factorials which are in arithmetic progression, the difference of the product is of the same form as the function itself, except that there is one factor less; and the difference of the fraction is similar to the fraction itself, with the exception of a new factor being added to the denominator.

 (17.) From the preceding expressions, a theorem for u_{x+n} may be deduced, in terms of u_x and its successive differences Δu_x , $\Delta^2 u_x$, $\Delta^3 u_x$, &c.

For since

$$u_{x+1} - u_x = \Delta u_x \text{ or } u_{x+1} = u_x + \Delta u_x, \\ \therefore \Delta u_{x+1} = \Delta u_x + \Delta(\Delta u_x) = \Delta u_x + \Delta^2 u_x.$$

But

$$u_{x+2} = u_{x+1} + \Delta u_{x+1} \\ = u_x + \Delta u_x + \Delta u_x + \Delta^2 u_x \\ = u_x + 2 \Delta u_x + \Delta^2 u_x.$$

And

$$u_{x+3} = u_{x+2} + 2 \Delta u_{x+1} + \Delta^2 u_{x+1} \\ = u_x + \Delta u_x + 2 \Delta u_x + 2 \Delta^2 u_x + \Delta^2 u_x + \Delta^3 u_x \\ = u_x + 3 \Delta u_x + 3 \Delta^2 u_x + \Delta^3 u_x.$$

The form of these expressions, the numerical coefficients of which follow the law of the coefficients of the binomial theorem, would finally lead us to the equation

$$u_{x+n} = u_x + n \Delta u_x + n \frac{n-1}{2} \Delta^2 u_x + \frac{n \cdot n-1 \cdot n-2}{1 \cdot 2 \cdot 3} \Delta^3 u_x + \&c.;$$

the truth, however, of this assumption may be thus shown.

 Let the value for u_{x+n} be supposed to be true:

 Then $u_{x+n+1} = u_{x+n} + \Delta u_{x+n}$

$$= u_x + n \Delta u_x + \frac{n \cdot n-1}{1 \cdot 2} \Delta^2 u_x + \frac{n \cdot n-1 \cdot n-2}{1 \cdot 2 \cdot 3} \Delta^3 u_x + \&c.;$$

$$+ \Delta u_x + n \Delta^2 u_x + \frac{n \cdot n-1}{1 \cdot 2} \Delta^3 u_x + \&c.$$

$$= u_x + (n+1) \Delta u_x + \frac{(n+1) \cdot n}{1 \cdot 2} \Delta^2 u_x + \frac{(n+1) \cdot n \cdot (n-1)}{1 \cdot 2 \cdot 3} \Delta^3 u_x + \&c.;$$

 whence it appears that if the theorem be true for any one term it is true for the next succeeding. Now we have shown that the law of the coefficient does obtain, when $n=2$, and also when $n=3$; the theorem is therefore universally true.

 (18.) The expression for u_{x+n} is very useful in finding the general term of a series when the differences are given.

 For first writing x for n , and then putting $n=0$, we have for the $(x+1)^{\text{th}}$ term, or u_x

$$u_x = u_0 + x \Delta u_0 + x \frac{x-1}{2} \Delta^2 u_0 + \frac{x \cdot x-1 \cdot x-2}{1 \cdot 2 \cdot 3} \Delta^3 u_0 + \&c.$$

$$\therefore x^{\text{th}} \text{ term or } u_{x-1} = u_0 + (x-1) \Delta u_0 + \frac{x-1 \cdot x-2}{1 \cdot 2} \Delta^2 u_0 + \frac{x-1 \cdot x-2 \cdot x-3}{1 \cdot 2 \cdot 3} \Delta^3 u_0 + \&c.$$

Calculus of
Finite
Differences.

Example. Find the general term of the series $19 + 28 + 39 + 52 + \&c.$: arranging the terms,

$$19 + 28 + 39 + 52 + \&c.$$

$$9 + 11 + 13 + \&c. \text{ first differences.}$$

$$2 + 2 + 2 + \&c. \text{ second differences.}$$

$$0 + 0 + 0 + \&c. \text{ third differences.}$$

Here

$$u_0 = 19, \Delta u_0 = 9, \Delta^2 u_0 = 2, \Delta^3 u_0 = 0;$$

$$\therefore u_{x-1} = 19 + (x-1)9 + \frac{(x-1)(x-2)}{1 \cdot 2} 2$$

$$= 10 + 9x + x^2 - 3x + 2 = x^2 + 6x + 12;$$

and by putting 1, 2, 3, &c. for x , the successive terms of the series will be found.

(19.) Having found the value of u_{x+n} in terms of u_x and its differences, we shall now find $\Delta^n u_x$ in terms of u_{x+n} and its preceding values.

For since

$$\begin{aligned} \Delta u_x &= u_{x+1} - u_x \text{ and } \Delta u_{x+1} = u_{x+2} - u_{x+1} \\ \therefore \Delta^2 u_x &= \Delta u_{x+1} - \Delta u_x = (u_{x+2} - u_{x+1}) - (u_{x+1} - u_x) \\ &= u_{x+2} - 2u_{x+1} + u_x, \end{aligned}$$

and

$$\begin{aligned} \Delta^3 u_x &= \Delta u_{x+2} - 2\Delta u_{x+1} + \Delta u_x \\ &= u_{x+3} - u_{x+2} - 2(u_{x+2} - u_{x+1}) + u_{x+1} - u_x \\ &= u_{x+3} - 3u_{x+2} + 3u_{x+1} - u_x, \end{aligned}$$

the law of the coefficients apparently following that of the coefficients of the expanded binomial $(a-b)^n$, and we shall have by analogy

$$\Delta^n u_x = u_{x+n} - n \cdot u_{x+n-1} + n \frac{n-1}{2} u_{x+n-2} - \frac{n \cdot n-1 \cdot n-2}{1 \cdot 2 \cdot 3} u_{x+n-3} + \&c.$$

Assuming this series to express the true value of $\Delta^n u_x$,

$$\therefore \Delta^{n+1} u_x = \Delta^n u_{x+1} - \Delta^n u_x$$

$$= u_{x+n+1} - n u_{x+n} + \frac{n \cdot n-1}{1 \cdot 2} u_{x+n-1} - \frac{n \cdot n-1 \cdot n-2}{1 \cdot 2 \cdot 3} u_{x+n-2} + \&c.$$

$$- u_{x+n} + n \cdot u_{x+n-1} - \frac{n \cdot n-1}{2} u_{x+n-2} + \&c.$$

$$= u_{x+n+1} - (n+1) u_{x+n} + \frac{n+1 \cdot n}{1 \cdot 2} u_{x+n-1} - \frac{n+1 \cdot n \cdot n-1}{1 \cdot 2 \cdot 3} u_{x+n-2} + \&c.$$

Hence if the law be true for the index n , it is true for the index $n+1$, and we have seen that it is true when $n=2$, and when $n=3$; it is therefore true when $n=4$, and thus by successive inductions is always true.

(20.) If $\Delta^n u_x = 0$, or if the differences at length became constant, we have

$$u_{x+n} - n u_{x+n-1} + \frac{n \cdot n-1}{1 \cdot 2} u_{x+n-2} - \frac{n \cdot n-1 \cdot n-2}{1 \cdot 2 \cdot 3} u_{x+n-3} + \&c. \pm u_x = 0;$$

or, putting $x=1$,

$$u_{n+1} = n u_n - n \frac{n-1}{2} \cdot u_{n-1} + \frac{n \cdot n-1 \cdot n-2}{1 \cdot 2 \cdot 3} u_{n-2} - \&c. \mp u_1;$$

whence it appears that any one term, as u_{n+1} , is expressed by a function of the preceding terms multiplied by constant coefficients, or that a series which has constant differences of any order is a recurring one: the converse of this proposition is not however true.

(21.) We may here make some brief remarks upon a system of notation which has been applied to the formulæ for u_{x+n} , and $\Delta^n u_x$. The letter Δ has hitherto been considered as the symbol of an operation performed upon the function u_x ; so long, therefore, as we remember its primary meaning, we are at liberty to put any expression involving Δ into another form, provided we do not change its value.

Now in the expression

$$u_{x+n} = u_x + n \Delta u_x + n \frac{n-1}{1 \cdot 2} \Delta^2 u_x + \frac{n \cdot n-1 \cdot n-2}{1 \cdot 2 \cdot 3} \Delta^3 u_x + \&c.,$$

if we consider u_x to be separated from Δ , Δ^2 , Δ^3 , &c., we may write

$$u_{x+n} = u_x \left\{ 1 + n \Delta + n \frac{n-1}{2} \Delta^2 + \frac{n \cdot n-1 \cdot n-2}{1 \cdot 2 \cdot 3} \Delta^3 + \&c. \right\};$$

but the expression within the bracket may be expressed by $(1 + \Delta)^n$, for this quantity when expanded will produce precisely the same series in form. Then, finally, we may consider u_{x+n} to be expressed by the equation $u_{x+n} = (1 + \Delta)^n u_x$, the right-hand side of the equation being considered only as the representation of the value of u_{x+n} in terms of u_x and its differences.

Calculus of
Finite
Differences.

Again, since $\Delta^n u_x$ may be written $(1 + \Delta - 1)^n u_x$; for Δ^n and $(1 + \Delta - 1)^n$ have the same meaning.

$$\therefore \Delta^n u_x = u_x \left\{ (1 + \Delta)^n - n(1 + \Delta)^{n-1} + n \frac{n-1}{2} (1 + \Delta)^{n-2} - \frac{n(n-1)(n-2)}{1 \cdot 2 \cdot 3} (1 + \Delta)^{n-3} + \&c. \right\}$$

$$= \overline{1 + \Delta}^n u_x - n(1 + \Delta)^{n-1} u_x + \frac{n(n-1)}{1 \cdot 2} (1 + \Delta)^{n-2} u_x - \frac{n(n-1)(n-2)}{1 \cdot 2 \cdot 3} (1 + \Delta)^{n-3} u_x + \&c.$$

But from what has preceded $(1 + \Delta)^n u_x$ is the expression for u_{x+n} ; $(1 + \Delta)^{n-1} u_x$ for u_{x+n-1} ; $(1 + \Delta)^{n-2} u_x$ that for u_{x+n-2} , &c.

$$\therefore \Delta^n u_x = u_{x+n} - n u_{x+n-1} + n \frac{n-1}{2} u_{x+n-2} - \&c.;$$

whence it appears how readily the expression for the n th difference of any function u_x may be obtained by means of the notation which has been just used: namely, that notation by which we have expressed the expansion of u_{x+n} under the symbol $(1 + \Delta)^n u_x$.

At present, however, we cannot pursue this subject further, but other applications of this concise system of notation will no doubt occur to the reader.

(22.) The formula $u_{x+2} = u_x + 2 \Delta u_x + \Delta^2 u_x = u_{x+1} + \Delta u_x + \Delta^2 u_x = u_{x+1} + (u_{x+1} - u_x) + \Delta^2 u_x$ conducts us to an expression very useful in the arithmetic of sines.

For suppose $u_x = \sin x \theta$,

$$\therefore u_{x+2} = \sin (x + 2) \theta = \sin (x \theta + 2 \theta);$$

also we have seen that

$$\Delta^2 u_x = -4 \sin^2 \frac{\theta}{2} \cdot \sin (x \theta + \theta),$$

$\therefore$ making the requisite substitutions in the formulæ for u_{x+2} , we have

$$\sin (x \theta + 2 \theta) = \sin (x \theta + \theta) + (\sin (x \theta + \theta) - \sin x \theta) - 4 \sin^2 \frac{\theta}{2} \cdot \sin (x \theta + \theta);$$

and making x successively = 0, 1, 2, 3, 4, &c. and $\theta = 1^\circ$, we have

$$\begin{aligned} \sin 2^\circ &= \sin 1^\circ + (\sin 1^\circ - \sin 0^\circ) - \sin 1^\circ (2 \sin 30')^2 \\ \sin 3^\circ &= \sin 2^\circ + (\sin 2^\circ - \sin 1^\circ) - \sin 2^\circ (2 \sin 30')^2 \\ \sin 4^\circ &= \sin 3^\circ + (\sin 3^\circ - \sin 2^\circ) - \sin 3^\circ (2 \sin 30')^2 \\ &\&c. \quad \&c. \end{aligned}$$

and having computed $\sin 1^\circ$ and $\sin 30'$, by some independent formula, for the sine in terms of the arc, the sines of the arcs will be found by addition and subtraction only.

Again, let $\theta = 1'$, and for $x + 2$ put $x + 1$;

$$\therefore \sin (x' + 1') = \sin x' + (\sin x' - \sin x' - 1') - \sin x' (2 \sin 30'')^2;$$

whence, knowing $\sin 30''$ and $\sin 1'$, the sines of minutes may be found; and by assuming $x = z \cdot 60 + \phi$, a formula may be found by which the sines of arcs consisting of degrees and minutes may be found.

(23.) Since, as we have seen in a preceding article, when n is of the form $4m$,

$$\Delta^n \sin \theta = + \left(2 \sin \frac{\theta}{2} \right)^n \left\{ \sin (x + n) \theta \right\}$$

$$\Delta^{n-1} \sin x \theta = - \left(2 \sin \frac{\theta}{2} \right)^{n-1} \left\{ \cos \left(x + n - \frac{1}{2} \right) \theta \right\}$$

$$\Delta^{n-2} \sin x \theta = - \left(2 \sin \frac{\theta}{2} \right)^{n-2} \left\{ \sin x + n - 1 \theta \right\},$$

$$\therefore \Delta^{n-1} \sin x \theta + \Delta^{n-2} \sin x \theta = - \left(2 \sin \frac{\theta}{2} \right)^{n-2} \left\{ 2 \sin \frac{\theta}{2} \cdot \cos x + n - \frac{1}{2} \theta + \sin x + n - 1 \theta \right\};$$

$$\text{and } \therefore \sin (x + n - 1) \theta = \sin \left(\left(x + n - \frac{1}{2} \right) - \frac{1}{2} \right) \theta$$

$$= - \left(2 \sin \frac{\theta}{2} \right)^{n-2} \left(\sin x + n - \frac{1}{2} \cdot \cos \frac{\theta}{2} + \sin \frac{\theta}{2} \cdot \cos x + n - \frac{1}{2} \theta \right)$$

$$= - \left(2 \sin \frac{\theta}{2} \right)^{n-2} (\sin x + n) \theta.$$

Multiplying both sides by $-\left(2 \sin \frac{\theta}{2} \right)^2$, and transposing,

$$\therefore \left(2 \sin \frac{\theta}{2} \right)^n \sin x + n \theta = - \left(2 \sin \frac{\theta}{2} \right)^2 \left\{ \Delta^{n-1} \sin x \theta + \Delta^{n-2} \sin x \theta \right\}$$

$$\text{or } \Delta^n \sin x \theta = - \left(2 \sin \frac{\theta}{2} \right)^2 \left\{ \Delta^{n-1} \sin x \theta + \Delta^{n-2} \sin x \theta \right\}$$

Calculus of Finite Differences. a formula given by Lagrange; the other cases, when n is an odd number, may be similarly proved; the formula is however general. Calculus of Finite Differences.

Thus having given any two successive differences of the sine of an arc, the rest may be found; and thus the sines may be computed by means of simple additions and subtractions.

(24.) The calculation of logarithms, always laborious, is yet much facilitated by the method of differences. The following example, the numerical results of which are taken from Lacroix, will be an instance of its use.

Let $u_x = \log x$, $\therefore \Delta \log x = \log(x+1) - \log x = \log\left(1 + \frac{1}{x}\right)$

$$= M \left\{ \frac{1}{x} - \frac{1}{2} \frac{1}{x^2} + \frac{1}{3} \cdot \frac{1}{x^3} - \&c. \right\}.$$

$$\Delta^2 \log x = \log(x+2) - 2 \log(x+1) + \log x$$

$$= \log\left(\frac{x+2}{x}\right) - 2 \log\left(\frac{x+1}{x}\right)$$

$$= M \left\{ \frac{2}{x} - \frac{1}{2} \frac{4}{x^2} + \frac{1}{3} \cdot \frac{8}{x^3} - \&c. - 2 \left(\frac{1}{x} - \frac{1}{2} \frac{1}{x^2} + \frac{1}{3} \frac{1}{x^3} - \&c. \right) \right\}$$

$$= -M \left\{ \frac{1}{x^2} - \frac{2}{x^3} + \&c. \right\}.$$

$$\Delta^3 \log x = \log(x+3) - 3 \log(x+2) + 3 \log(x+1) - \log x$$

$$= \log\left(1 + \frac{3}{x}\right) - 3 \log\left(1 + \frac{2}{x}\right) + 3 \log\left(1 + \frac{1}{x}\right)$$

$$= M \cdot \left(\frac{2}{x^3} - \&c. \right).$$

And

$$\Delta^4 \log x = -M \left(\frac{6}{x^4} - \&c. \right).$$

If higher orders of differences be required, we may, by pursuing a similar process, find them; but in general, the values of the third differences are so small that we may stop there, as the omission of the following terms will not sensibly affect the result. The differences being computed, they are substituted in the equation $u_n = u + n \Delta u + \frac{n-1}{2} \Delta^2 u + \frac{n-1}{1 \cdot 2 \cdot 3} \Delta^3 u$, and proper values being given to (n) , the value of u_n , which is the object sought, is discovered.

Thus if

$$x = 10000, \therefore u = \log 10000 = 4.$$

Then

$$\Delta u = 0.00004 \ 34272 \ 76863$$

$$\Delta^2 u = -0.00000 \ 00043 \ 42076$$

$$\Delta^3 u = 0.00000 \ 00000 \ 00868,$$

and let it be required to find the logarithm of 10006.

Here

$$n = 6, \text{ and } u_6 = u + 6 \Delta u + 15 \Delta^2 u + 20 \Delta^3 u;$$

and computing the terms of this equation, we shall find

$$u_6 = \log 10006 = 4.00025 \ 94995 \ 47398.$$

We might, however, have obtained the same result, had we formed a table of differences, and then the operation would have been performed by simple additions and subtractions.

In the common tables of Hutton the logarithm is only given to seven places of decimals; so long, therefore, as the omission of the other terms of the equation does not affect the value of this figure, the differences calculated from the series will be applicable to find the logarithms required; but when this figure is altered, as we can find by trial, we must start from this point, and we compute Δu , $\Delta^2 u$ and $\Delta^3 u$. It is easy to find when this takes place; thus if $n = 50$, the value of the first neglected term $= \frac{50 \times 49 \times 48 \times 47}{1 \cdot 2 \cdot 3 \cdot 4} \times -M \left\{ \frac{6}{x^4} - \&c. \right\}$ is found only to influence the value of the sixteenth figure in the decimal part of the logarithm of 10050.

(25.) Other series more convergent than those given in the last article are readily found, which will render the calculation of Δu , $\Delta^2 u$, and $\Delta^3 u$, much less laborious.

For since $\log(x+1) = \log x + 2M \left\{ \frac{1}{2x+1} + \frac{1}{3(2x+1)^3} + \frac{1}{5(2x+1)^5} + \&c. \right\},$

$$\therefore \Delta \log x = \log(x+1) - \log x = 2M \left\{ \frac{1}{2x+1} + \frac{1}{3(2x+1)^3} + \frac{1}{5(2x+1)^5} \right\}.$$

Again

$$\therefore \log(z+1) = \log z + M \left\{ \frac{1}{z} - \frac{1}{2z^2} + \frac{1}{3z^3} - \frac{1}{4z^4} + \&c. \right\},$$

Calculus of
Finite
Differences.

Calculus of
Finite
Differences.

$$\log(z-1) = \log z - M \left\{ \frac{1}{z} + \frac{1}{2} \frac{1}{z^2} + \frac{1}{3} \frac{1}{z^3} + \frac{1}{4} \frac{1}{z^4} + \&c. \right\},$$

$$\therefore \log(z+1) + \log(z-1) - 2 \log z = -2M \left\{ \frac{1}{2z^2} + \frac{1}{4z^4} + \&c. \right\}.$$

Let

$$z = x + 1,$$

$$\therefore \log(x+2) - 2 \log(x+1) + \log x = \Delta^2 \log x = -2M \left\{ \frac{1}{2(x+1)^2} + \frac{1}{4(x+1)^4} + \&c. \right\};$$

and when x is a large number, it is found to be only necessary to compute the first two terms of the expression for $\Delta \log x$.

"Indeed when $x = 10000$, the second term $2M \cdot \frac{1}{(2x+1)^2}$ is only .00000 00000 00036, and the following term has twenty-two ciphers between the decimal point and the first significant figure, and with respect to $\Delta^2 \log x$, the first term is quite sufficient for the second term, when $x = 10000$ amounts only to .00000 00000 00000 0217."

Hence if N be any number above 10000, we may use without error the formulæ $\Delta \log N = 2M \left\{ \frac{1}{2N+1} + \frac{1}{3} \frac{1}{(2N+1)^3} \right\}$ and $\Delta^2 \log N = -\frac{M}{(N+1)^2}$.

(26.) We next proceed to investigate a formula for the computation of the logarithms of sines.

Since

$$\log(n+z) = \log(n) + 2M \left\{ \frac{z}{2n+z} + \frac{1}{3} \frac{z^3}{(2n+z)^3} + \frac{1}{5} \frac{z^5}{(2n+z)^5} + \&c. \right\};$$

let

$$n = \sin x \theta \text{ and } n+z = \sin x + 1 \cdot \theta \therefore z = \Delta \sin x \theta.$$

$$\therefore \log(\sin x + 1 \cdot \theta) = \log(\sin x \theta) + 2M \left\{ \frac{\Delta \sin x \theta}{2 \sin x \theta + \Delta \sin x \theta} + \frac{1}{3} \left(\frac{\Delta \cdot \sin x \theta}{2 \sin x \theta + \Delta \sin x \theta} \right)^3 + \&c. \right\};$$

a formula given by Delambre, but which was put under another form, to which the above is reducible, of $x\theta = y$ and $\theta = h$;

and

and

$$\therefore \Delta \sin x \theta = \sin(y+h) - \sin y;$$

$$\therefore \log(\sin y + h) = \log(\sin y) + 2M \cdot \left\{ \frac{\sin y + h - \sin y}{\sin y + h + \sin y} + \frac{1}{3} \cdot \left(\frac{\sin y + h - \sin y}{\sin y + h + \sin y} \right)^3 + \&c. \right\}.$$

Now let

and

$$x = 45, \theta = 1^\circ, \therefore \sin x \theta = \sin 45^\circ = \frac{1}{\sqrt{2}}.$$

$$\log \sin x \theta = \frac{1}{2} \log \frac{1}{2};$$

$$\therefore \log \sin 46 = \frac{1}{2} \log \frac{1}{2} + 2M \left\{ \frac{\Delta \sin 45}{2 \sin 45 + \Delta \sin 45} + \frac{1}{3} \left(\frac{\Delta \sin 45}{2 \sin 45 + \Delta \sin 45} \right)^3 + \&c. \right\}.$$

And in a similar manner may the logarithms of the series of other arcs as far as 90 be found; and since as the arc increases the $\Delta \sin x \theta$ decreases, therefore the series becomes the more convergent as we approach 90°, and the sines of arcs greater than 45° being known, the sines of arcs greater than 45° may be computed from the formula

$$\sin \frac{A}{2} = \frac{\sin A}{2 \cos \frac{A}{2}} = \frac{\sin A}{2 \sin \left(90 - \frac{A}{2} \right)};$$

$$\therefore \log \sin \frac{A}{2} = \log \sin A - \log 2 - \log \sin \left(90 - \frac{A}{2} \right).$$

$$\log \sin 31 = \log \sin 62 - \log 2 - \log \sin 59.$$

Thus

A singular formula for the $\log(\cos x)$, also given by Delambre, may have place here.

$$\therefore \cos^2 x = (1 - \sin^2 x) = (1 - y^2) \text{ suppose.}$$

$$\therefore \log \cos^2 x = 2 \log \cos x = \log(1 - y^2) = -M \left\{ y^2 + \frac{y^4}{2} + \frac{y^6}{3} + \frac{y^8}{4} + \&c. \right\},$$

$$\therefore \log \cos x = -M \left\{ \frac{y^2}{2} + \frac{y^4}{4} + \frac{y^6}{6} + \frac{y^8}{8} + \&c. \right\}$$

$$= -M \left\{ \frac{1}{2} (\sin x)^2 + \frac{1}{4} (\sin x)^4 + \frac{1}{6} (\sin x)^6 + \&c. \right\}.$$

(27.) We have already found the expression for $\Delta(u_x v_x)$. We now proceed to find those for $\Delta^2(u_x v_x)$, and $\Delta^3(u_x v_x)$. We have seen that

$$\Delta(u_x v_x) = u_x \Delta v_x + v_x \Delta u_x + \Delta u_x \cdot \Delta v_x (1),$$

and

$$\therefore \Delta^2(u_x v_x) = \Delta(u_x \Delta v_x) + \Delta(v_x \Delta u_x) + \Delta(\Delta u_x \cdot \Delta v_x),$$

each term of which may be found by means of the equation (1).

$$\text{Thus } \Delta(u_x \cdot \Delta v_x) = u_x \cdot \Delta^2 v_x + \Delta v_x \cdot \Delta u_x + \Delta u_x \cdot \Delta^2 v_x$$

$$\Delta(v_x \Delta u_x) = v_x \Delta^2 u_x + \Delta u_x \cdot \Delta v_x + \Delta v_x \cdot \Delta^2 u_x$$

$$\Delta \cdot (\Delta u_x \cdot \Delta v_x) = \Delta u_x \cdot \Delta^2 v_x + \Delta v_x \cdot \Delta^2 u_x + \Delta^2 v_x \cdot \Delta^2 u_x;$$

$$\therefore \Delta(u_x v_x) = u_x \Delta^2 v_x + v_x \Delta^2 u_x + 2 \Delta u_x \cdot \Delta v_x + 2 \Delta u_x \Delta^2 v_x + 2 \Delta v_x \cdot \Delta^2 u_x + \Delta^2 u_x \cdot \Delta^2 v_x.$$

$\Delta^3(u_x v_x)$ may be found in the same manner from equation (1), but the labour would obviously be considerable, and the law of the coefficients is not sufficiently manifest to abridge the labour. The artifice of separating the symbols of operation from those of quantity is here eminently useful.

First, let an accent be placed over the Δ which is prefixed to v_x , to indicate that Δ' applies solely to that function, while Δ refers only to u_x , so that we may write indifferently

$$u_x \Delta' v_x \text{ or } \Delta' u_x v_x, \Delta^2 u_x \Delta'^2 v_x \text{ or } \Delta^2 \Delta'^2 u_x v_x,$$

or in general

$$\Delta^m u_x \cdot \Delta'^n v_x \text{ may be put } \Delta^m \Delta'^n u_x v_x;$$

but we must keep in mind that Δ' does not indicate any different operation from Δ , but that it solely belongs to v_x .

This being premised, resuming the equation for $\Delta u_x v_x$, we have

$$\begin{aligned} \Delta(u_x v_x) &= u_x \Delta' v_x + v_x \Delta u_x + \Delta u_x \Delta' v_x \\ &= (\Delta' + \Delta + \Delta \Delta') u_x v_x; \end{aligned}$$

and

$$\begin{aligned} \therefore \Delta^2(u_x v_x) &= (\Delta + \Delta' + \Delta \Delta') \Delta(u_x v_x) \\ &= (\Delta + \Delta' + \Delta \Delta')^2 \cdot u_x v_x \\ &= (\Delta^2 + \Delta'^2 + \Delta^2 \Delta'^2 + 2 \Delta \Delta' + 2 \Delta^2 \Delta' + 2 \Delta \Delta'^2) u_x v_x \\ &= v_x \Delta^2 u_x + u_x \Delta'^2 v_x + \Delta^2 u_x \Delta' v_x + 2 \Delta u_x \Delta' v_x + 2 \Delta' v_x \Delta^2 u_x + 2 \Delta u_x \Delta'^2 v_x; \end{aligned}$$

which, by obliterating the accent, becomes the same expression that was previously obtained.

(28.) Similarly, since

$$\Delta^3(u_x v_x) = (\Delta + \Delta' + \Delta \Delta')^3 \cdot \Delta(u_x v_x),$$

$$\therefore = (\Delta + \Delta' + \Delta \Delta')^3 u_x v_x,$$

$$\therefore \Delta^n(u_x v_x) = (\Delta + \Delta' + \Delta \Delta')^n u_x v_x.$$

But

$$(\Delta + \Delta' + \Delta \Delta')^n = \{\Delta + \Delta' (1 + \Delta)\}^n,$$

$$\therefore \Delta^n(u_x v_x) = \{\Delta + \Delta' (1 + \Delta)\}^n u_x v_x$$

$$= \left\{ \Delta^n + n \Delta^{n-1} \cdot (1 + \Delta) \cdot \Delta' + n \frac{n-1}{2} \cdot \Delta^{n-2} \cdot \Delta'^2 (1 + \Delta)^2 + \&c. \right\} u_x v_x.$$

$$\text{But } \therefore (1 + \Delta)^m u_x = u_{x+m}, \therefore \Delta^{n-m} (1 + \Delta)^m u_x = \Delta^{n-m} u_{x+m};$$

$$\therefore \Delta^n(u_x v_x) = v_x \Delta^n u_x + n \cdot \Delta^{n-1} u_{x+1} \cdot \Delta v_x + n \frac{n-1}{2} \cdot \Delta^{n-2} u_{x+2} \cdot \Delta^2 v_x + \&c.$$

the law of which is sufficiently manifest.

(29.) By the same system of notation we may arrive at the n th difference of the product of any number of functions. We shall, however, only indicate the process.

Since

$$\Delta^n(u_x v_x) = (\Delta + \Delta' + \Delta \Delta')^n u_x v_x,$$

and that

$$\Delta + \Delta' + \Delta \Delta' = \overline{1 + \Delta} \cdot \overline{1 + \Delta'} - 1,$$

$$\therefore \Delta^n(u_x v_x) = \overline{(1 + \Delta \cdot 1 + \Delta' - 1)^n} u_x v_x.$$

And if we have any number of functions, as $u_x v_x u'_x v'_x$, &c., and suppose Δ'' to refer to u'_x , Δ''' to v'_x , &c., we shall obviously obtain

$$\Delta^n(u_x v_x u'_x v'_x \dots) = \overline{(1 + \Delta \cdot 1 + \Delta' \cdot 1 + \Delta'' \dots - 1)^n} u_x v_x u'_x v'_x \dots;$$

and the right-hand side of the equation being expanded, and the accented letters being prefixed to their respective functions, the true developement of the difference will be found.

(30.) The particular values which in some cases the n th differences of u_x take, demand our attention, and the results which arise from one particular instance are curious and useful.

(31.) Since $\Delta^n u_x = u_{x+n} - n u_{x+n-1} + \frac{n(n-1)}{2} u_{x+n-2} - \frac{n(n-1)(n-2)}{1 \cdot 2 \cdot 3} u_{x+n-3} + \&c.$, we can, by giving particular values to u_x , readily find values for the n th differences of functions.

Thus, let $u_x = x^m$, then $u_{x+n} = (x+n)^m$, $u_{x+n-1} = (x+n-1)^m$, &c.;

$$\therefore \Delta^n x^m = (x+n)^m - n(x+n-1)^m + \frac{n(n-1)}{2} (x+n-2)^m - \frac{n(n-1)(n-2)}{1 \cdot 2 \cdot 3} (x+n-3)^m + \&c.$$

But when $n = m$, we have seen, in a preceding article that

$$\Delta^m x^m = 1 \cdot 2 \cdot 3 \dots m - 2 \cdot m - 1 \cdot m;$$

$\therefore$ whatever be the value of x , and first writing m for n ,

$$(x+m)^m - m(x+m-1)^m + \frac{m(m-1)}{2} (x+m-2)^m - \&c. = 1 \cdot 2 \cdot 3 \dots m.$$

If, now, we make $x = 0$, we have the singular result

$$m^m - m(m-1)^m + \frac{m(m-1)}{2} (m-2)^m - \&c. = 1 \cdot 2 \cdot 3 \dots m.$$

Again, if in the general value for $\Delta^n x^m$, we make $x = 0$, we have

$$\Delta^n 0^m = n^m - n(n-1)^m + \frac{n(n-1)}{2} (n-2)^m - \frac{n(n-1)(n-2)}{1 \cdot 2 \cdot 3} (n-3)^m + \&c.$$

And since $\Delta^m x^m$ is constant, and equal $1 \cdot 2 \cdot 3 \dots m$, therefore $\Delta^n 0^m$ is equal to zero when $n > m$, and equal to the product of the first m integers when $m = n$.

We may remark that, since x^m is the general term of the series, $0^m + 1^m + 2^m + 3^m + \&c.$, $\Delta^n 0^m$ is the symbol for the first term of the n th order of differences of this series.

(32.) Resuming the equation

$$\Delta^n x^m = (x+n)^m - n(x+n-1)^m + \frac{n(n-1)}{1 \cdot 2} (x+n-2)^m - \frac{n(n-1)(n-2)}{1 \cdot 2 \cdot 3} (x+n-3)^m + \&c.,$$

which, by changing the place of x , may be written

$$= (n+x)^m - n(n-1+x)^m + \frac{n(n-1)}{2} (n-2+x)^m - \frac{n(n-1)(n-2)}{1 \cdot 2 \cdot 3} (n-3+x)^m + \&c.,$$

and expanding each term according to the powers of x by the binomial theorem, we shall obtain

$$\begin{aligned} \Delta^n x^m &= n^m - n \cdot (n-1)^m + \frac{n(n-1)}{2} (n-2)^m - \frac{n(n-1)(n-2)}{1 \cdot 2 \cdot 3} (n-3)^m + \&c. \\ &+ m \cdot \left\{ n^{m-1} - n(n-1)^{m-1} + \frac{n(n-1)}{2} (n-2)^{m-1} - \&c. \right\} x \\ &+ m \cdot \frac{m-1}{2} \cdot \left\{ n^{m-2} - n(n-1)^{m-2} + \frac{n(n-1)}{2} (n-2)^{m-2} - \&c. \right\} x^2 \\ &+ \&c. \\ &= \Delta^n 0^m + m \Delta^n 0^{m-1} \cdot x + \frac{m(m-1)}{2} \Delta^n 0^{m-2} \cdot x^2 + \frac{m(m-1)(m-2)}{1 \cdot 2 \cdot 3} \Delta^n 0^{m-3} \cdot x^3 + \&c. \\ &+ \frac{m(m-1)(m-2) \dots (m-n+1)}{1 \cdot 2 \cdot 3 \dots m-n} \Delta^n 0^n \cdot x^{m-n}; \end{aligned}$$

whence, after computing the values of $\Delta^n 0^m$, $\Delta^n 0^{m-1}$, &c., the values of $\Delta^n x^m$ may be found.

(33.) These values, $\Delta^n 0^m$, $\Delta^n 0^{m-1}$, &c. are very important in the theory of series, and in his Collection of Examples on the Calculus of Finite Differences, Sir John Herschell has given the values of $\Delta^n 0^m$ as far as $\Delta^{10} 0^{10}$ in a Table which we have annexed.

These numbers are computed from the formula

$$\Delta^n 0^m = n^m - n(n-1)^m + \frac{n(n-1)}{2} (n-2)^m - \frac{n(n-1)(n-2)}{1 \cdot 2 \cdot 3} (n-3)^m + \&c.$$

Thus, let $m = 3$, then, making $n = 1, 2, 3$, successively,

$$\Delta^1 0^3 = 1^3 = 1$$

$$\Delta^2 0^3 = 2^3 - 2 \cdot 1^3 = 8 - 2 = 6$$

$$\Delta^3 0^3 = 3^3 - 3 \cdot 2^3 + 3 \cdot 1^3 = 30 - 24 = 6$$

$$\Delta^4 0^3 = 4^3 - 4 \cdot 3^3 + 6 \cdot 2^3 - 4 = 112 - 112 = 0,$$

the last result we know *à priori*.

Calculus of
Finite
Differences.

Similarly may be found the other values in the annexed Table, and which may be extended to any values of m and n . Also

Calculus of
Finite
Differences.

$$\begin{aligned}\Delta^6 \cdot 0^6 &= 6^6 - 6 \cdot 5^6 + 15 \cdot 4^6 - 20 \cdot 3^6 + 15 \cdot 2^6 - 6 \\ &= 1679616 - 2343750 + 983040 - 131220 + 3840 - 6 \\ &= 2666496 - 2474976 = 191520.\end{aligned}$$

(34.) Next to find the value of $\Delta \cdot u_x$ and $\Delta^n u_x$ in terms of u_x , and its differential coefficients. Since u_x is a function of x , and u_{x+1} a function of $x+1$, therefore, by Taylor's theorem,

$$\Delta u_x = u_{x+1} - u_x = \frac{d \cdot u_x}{dx} + \frac{d^2 u_x}{dx^2} \cdot \frac{1}{2} + \frac{d^3 u_x}{dx^3} \cdot \frac{1}{2 \cdot 3} + \frac{d^4 u_x}{dx^4} \cdot \frac{1}{2 \cdot 3 \cdot 4} + \&c.$$

or, separating the symbols of operation from those of quantity,

$$\begin{aligned}&= u_x \cdot \left\{ \frac{d}{dx} + \frac{d^2}{dx^2} \cdot \frac{1}{1 \cdot 2} + \frac{d^3}{dx^3} \cdot \frac{1}{2 \cdot 3} + \frac{d^4}{dx^4} \cdot \frac{1}{2 \cdot 3 \cdot 4} + \&c. \right\} \\ &= u_x \cdot \{ e^{\frac{d}{dx}} - 1 \}.\end{aligned}$$

Since $e^{\frac{d}{dx}} - 1$ when expanded will produce a series exactly of the same form; and, similarly, we might infer that $\Delta^n u_x$ may be represented by $(e^{\frac{d}{dx}} - 1)^n u_x$.

But to prove, in a strict manner, this theorem, due to Lagrange; since $u_{x+n} = f(x+n)$, we may use Taylor's theorem, and put

$$\begin{aligned}u_{x+n} &= u_x + \frac{du_x}{dx} n + \frac{d^2 u_x}{dx^2} \frac{n^2}{1 \cdot 2} + \frac{d^3 u_x}{dx^3} \frac{n^3}{2 \cdot 3} + \&c. \\ &= u_x \left\{ 1 + \frac{d}{dx} n + \frac{d^2 n^2}{dx^2} \frac{1}{1 \cdot 2} + \frac{d^3 n^3}{dx^3} \frac{1}{2 \cdot 3} + \&c. \right\} \\ &= u_x e^{n \cdot \frac{d}{dx}} = u_x e^{nt}, \text{ where } t = \frac{d}{dx};\end{aligned}$$

and by writing $n-1$, $n-2$, &c. for n we shall have

$$u_{x+n-1} = u_x e^{(n-1)t}, \quad u_{x+n-2} = u_x e^{(n-2)t}, \quad \&c.$$

Now

$$\Delta^n \cdot u_x = u_{x+n} - n u_{x+n-1} + \frac{n(n-1)}{2} u_{x+n-2} - \frac{n(n-1)(n-2)}{1 \cdot 2 \cdot 3} u_{x+n-3} + \&c.;$$

therefore writing for u_{x+n} , u_{x+n-1} , &c. the values just obtained,

$$\begin{aligned}\Delta^n . u_x &= u_x \cdot \left\{ e^{nx} - n \cdot e^{(n-1)x} + \frac{n(n-1)}{2} e^{(n-2)x} - \frac{n(n-1)(n-2)}{1 \cdot 2 \cdot 3} e^{(n-3)x} + \&c. \right\} \\ &= u_x \cdot \left\{ (e^x)^n - n(e^x)^{n-1} + \frac{n(n-1)}{2} (e^x)^{n-2} - \frac{n(n-1)(n-2)}{2 \cdot 3} (e^x)^{n-3} + \&c. \right\} \\ &= u_x (e^x - 1)^n = u_x \cdot (e^{\frac{d}{dx}} - 1)^n.\end{aligned}$$

The preceding demonstration is due to Dr. Brinkley, and was given by him in the *Philosophical Transactions* for 1807.

(35.) Again, supposing that $f(\Delta)$ represents any function of Δ capable of being developed according to the powers of Δ , such that

$$\begin{aligned}f(\Delta) &= a + b\Delta + c\Delta^2 + e\Delta^3 + \&c., \\ \therefore f(\Delta) u_x &= a u_x + b\Delta u_x + c\Delta^2 u_x + e\Delta^3 u_x + \&c.\end{aligned}$$

by Lagrange's theorem just demonstrated,

$$\begin{aligned}&= a u_x + b(e^{\frac{d}{dx}} - 1) u_x + c(e^{\frac{d}{dx}} - 1)^2 u_x + e(e^{\frac{d}{dx}} - 1)^3 u_x + \&c., \\ \therefore f(\Delta) u_x &= u_x \cdot \{a + b(e^{\frac{d}{dx}} - 1) + c(e^{\frac{d}{dx}} - 1)^2 + \&c.\} \\ &= u_x \{a + b\Delta_1 + c\Delta_1^2 + \&c.\} \\ &= u_x f(\Delta_1) = u_x f(e^{\frac{d}{dx}} - 1): \end{aligned}$$

for this series having precisely the same form as that which results from the developement of $f(\Delta)$, it must be the same function of $(e^{\frac{d}{dx}} - 1)$ as $a + b\Delta + c\Delta^2 + \&c.$ is of Δ , and therefore may be represented by the same symbol; and

$$\therefore f(\Delta) u_x = f(e^{\frac{d}{dx}} - 1) u_x,$$

a theorem which is due to Arbogast.

(36.) Thus, suppose the form of the function to be such that

$$f(\Delta) = (1 + \Delta)^n;$$

then $\therefore$ for Δ we have written $1 + \Delta$,

$$\therefore f(e^{\frac{d}{dx}} - 1) = (1 + e^{\frac{d}{dx}} - 1)^n = e^{\frac{n}{dx}},$$

and

$$\therefore (1 + \Delta)^n u_x = e^{\frac{n}{dx}} . u_x = u_{x+n},$$

by Article (34.); and this is obviously true, since if $(1 + \Delta)^n$ be expanded, and each term multiplied by u_x , there will arise the series to which u_{x+n} is equal.

(37.) Again, if $f(\Delta) = (\log(1 + \Delta))^n$, we have

$$\{\log(1 + \Delta)\}^n u_x = \{\log(1 + e^{\frac{d}{dx}} - 1)\}^n u_x = \left(\frac{d}{dx}\right)^n u_x = \frac{d^n u_x}{dx^n};$$

whence, if $n = 1$,

$$\frac{d \cdot u_x}{dx} = u_x \log(1 + \Delta) = \Delta u_x - \frac{\Delta^2 u_x}{2} + \frac{\Delta^3 u_x}{3} - \&c.$$

(38.) This last result may be thus verified:

$$u_{x+n} = f(x + n) = u_x + \frac{d \cdot u_x}{dx} \cdot n + \frac{d^2 u_x}{dx^2} \cdot \frac{n^2}{1 \cdot 2} + \&c.$$

But

$$u_{x+n} = u_x + n\Delta u_x + \frac{n(n-1)}{2} \Delta^2 u_x + \frac{n \cdot (n-1)(n-2)}{1 \cdot 2 \cdot 3} \Delta^3 u_x + \&c.;$$

or, expanding according to the powers of n ,

$$\begin{aligned}&= u_x + n \left\{ \Delta \cdot u_x - \frac{1}{2} \Delta^2 \cdot u_x + \frac{1}{3} \Delta^3 \cdot u_x - \frac{1}{4} \Delta^4 \cdot u_x + \&c. \right\} \\ &\quad + \frac{n^2}{1 \cdot 2} \cdot \{ \Delta^2 \cdot u_x - \Delta^3 \cdot u_x + \&c. \} \\ &\quad + \&c.\end{aligned}$$

whence, equating the coefficients of n in both series,

$$\begin{aligned}\frac{d \cdot u_x}{dx} &= \Delta \cdot u_x - \frac{\Delta^2 \cdot u_x}{2} + \frac{\Delta^3 \cdot u_x}{3} - \frac{\Delta^4 \cdot u_x}{4} + \&c. \\ &= u_x \left\{ \frac{\Delta}{1} - \frac{\Delta^2}{2} + \frac{\Delta^3}{3} - \frac{\Delta^4}{4} + \&c. \right\} \\ &= u_x \log(1 + \Delta),\end{aligned}$$

the theorem in question.

Calculus of
Finite
Differences.

And, by collecting together the coefficients of $n^2, n^3, \&c.$, we may also find the values of $\frac{d^2 u_x}{dx^2}, \frac{d^3 u_x}{dx^3}, \&c.$ in terms of $\Delta \cdot u_x, \Delta^2 \cdot u_x, \&c.$, and thus verify the results which we might at once obtain from the equation $\frac{d^n u_x}{dx^n} = (\log(1+\Delta))^n u_x$, the general form of which will be, since $(\log(1+\Delta))^n = \Delta^n \left\{ 1 - \frac{\Delta}{2} + \frac{\Delta^2}{3} - \frac{\Delta^3}{4} + \&c. \right\}^n$, Calculus of
Finite
Differences.

$$\Delta^n \cdot u_x + A_1 \Delta^{n+1} \cdot u_x + A_2 \Delta^{n+2} \cdot u_x + A_3 \Delta^{n+3} \cdot u_x + \&c.$$

(39.) We have previously found a convenient formula for $\Delta^n \cdot x^m$ in terms of $\Delta^n \cdot 0^m, \Delta^{n+1} \cdot 0^{m-1}$, we can now deduce a general expression for $\Delta^n \cdot u_x$, dependent upon similar values.

Since $\Delta^n \cdot u_x = (e^{\frac{d}{dx}} - 1)^n u_x$, if the right-hand side of the equation be expanded, there will arise a series of the form

$$\begin{aligned} & \left(A_0 + A_1 \frac{d}{dx} + A_2 \frac{d^2}{dx^2} + A_3 \frac{d^3}{dx^3} + \&c. + A_m \frac{d^m}{dx^m} + \&c. \right) u_x \\ &= A_0 u_x + A_1 \frac{d \cdot u_x}{dx} + A_2 \frac{d^2 u_x}{dx^2} + A_3 \frac{d^3 u_x}{dx^3} + \&c. + A_m \frac{d^m \cdot u_x}{dx^m} + \&c. \end{aligned}$$

But if t be written for $\frac{d}{dx}$, it is evident that A_m is the coefficient of t^m , in the expansion of $(e^t - 1)^n$.

$$\text{Now} \quad (e^t - 1)^n = e^{nt} - n e^{(n-1)t} + \frac{n(n-1)}{2} e^{(n-2)t} - \&c.$$

$$\begin{aligned} &= 1 + nt + \frac{n^2 t^2}{1 \cdot 2} + \frac{n^3 t^3}{2 \cdot 3} + \&c. + \frac{n^m t^m}{1 \cdot 2 \cdot 3 \dots m} + \&c. \\ &- n \left\{ 1 + (n-1)t + \frac{(n-1)^2 t^2}{1 \cdot 2} + \&c. + \frac{(n-1)^m t^m}{1 \cdot 2 \cdot 3 \dots m} + \&c. \right\} \\ &+ \frac{n(n-1)}{2} \cdot \left\{ 1 + (n-2)t + \&c. + \frac{(n-2)^m t^m}{1 \cdot 2 \cdot 3 \dots m} + \&c. \right\} \\ &- \&c.; \end{aligned}$$

and $\therefore$ the coefficient of t^m in this expansion, or

$$A_m = \frac{n^m - n(n-1)^m + \frac{n(n-1)}{2}(n-2)^m - \&c.}{1 \cdot 2 \cdot 3 \dots m}.$$

$$\text{But} \quad n^m - n(n-1)^m + \frac{n(n-1)}{2}(n-2)^m - \&c. = \Delta^n \cdot 0^m \quad (\text{Article 31.});$$

$$\therefore A_m = \frac{\Delta^n \cdot 0^m}{1 \cdot 2 \cdot 3 \dots m},$$

which is equal to zero when n is greater than m , and $= 1 \cdot 2 \cdot 3 \dots m$ when $m = n$;

$$\therefore A_n = 1, A_{n+1} = \frac{\Delta^n \cdot 0^{n+1}}{1 \cdot 2 \dots (n+1)}, A_{n+2} = \frac{\Delta^n \cdot 0^{n+2}}{1 \cdot 2 \cdot 3 \dots (n+2)}, \&c.,$$

and therefore

$$\Delta^n \cdot u_x = \frac{d^n u_x}{dx^n} + \frac{\Delta^n \cdot 0^{n+1}}{1 \cdot 2 \dots (n+1)} \cdot \frac{d^{n+1} u_x}{dx^{n+1}} + \frac{\Delta^n \cdot 0^{n+2}}{1 \cdot 2 \dots (n+2)} \cdot \frac{d^{n+2} u_x}{dx^{n+2}} + \&c.$$

(39.) Hence we may find the numerical values of $\Delta^n \cdot 0^{n+1}, \Delta^n \cdot 0^{n+2}, \&c.$

$$\text{For since} \quad \Delta^n = (e^{\frac{d}{dx}} - 1)^n = (e^t - 1)^n = \left(t + \frac{t^2}{1 \cdot 2} + \frac{t^3}{2 \cdot 3} + \frac{t^4}{2 \cdot 3 \cdot 4} + \&c. \right)^n$$

$$= t^n \left\{ 1 + \frac{t}{1 \cdot 2} + \frac{t^2}{2 \cdot 3} + \&c. \right\}^n$$

$$= t^n \cdot \left\{ 1 + \frac{n}{1 \cdot 2} t + \frac{n(3n+1)}{2 \cdot 3 \cdot 4} t^2 + \frac{n^2 \cdot (n+1)}{3 \cdot 4 \cdot 4} t^3 + \&c. \right\}.$$

But from the expression for $\Delta^n \cdot u_x$, obtained in the preceding article, first separating the symbols of quantity u_x from the symbols of operation, and putting $\frac{d}{dx} = t$, we have

$$\Delta^n = (e^t - 1)^n = t^n \left\{ 1 + \frac{\Delta^n \cdot 0^{n+1}}{1 \cdot 2 \cdot 3 \dots (n+1)} t + \frac{\Delta^n \cdot 0^{n+2}}{1 \cdot 2 \dots (n+2)} t^2 + \frac{\Delta^n \cdot 0^{n+3}}{1 \cdot 2 \dots (n+3)} t^3 + \&c. \right\};$$

whence, by equating the coefficients of the same powers of t ,

CALCULUS OF FINITE DIFFERENCES.

241

Calculus of
Finite
Differences.

Calculus of
Finite
Differences.

$$\Delta^n \cdot 0^{n+1} = 1 \cdot 2 \cdot 3 \dots (n+1) \cdot \frac{n}{2} = \Delta^n \cdot 0^n \cdot \frac{n^2 + n}{2}.$$

$$\Delta^n \cdot 0^{n+2} = 1 \cdot 2 \cdot 3 \dots (n+2) \cdot \frac{3n^2 + n}{2 \cdot 3 \cdot 4}$$

$$\Delta^n \cdot 0^{n+3} = 1 \cdot 2 \cdot 3 \dots (n+3) \cdot \frac{n^3 + n}{3 \cdot 4^2}$$

&c. &c.;

and, similarly, may other terms be found.

Functions of two Variables.

(40.) Hitherto we have treated of functions of one variable only; we proceed to give a brief account of the direct method of differences when applied to functions of two variables, and the reasoning may be extended to functions of a greater number of variables.

The different values which a function $u_{x,y}$ of two variables takes when different values are given to x and y , x and y being supposed to increase by unity, will form a series of progressions which may be arranged in the following manner.

		Values of x .					
		0	1	2	3	4	x
Values of y .	0	$u_{0,0}$	$u_{1,0}$	$u_{2,0}$	$u_{3,0}$	$u_{4,0}$	$u_{x,0}$
	1	$u_{0,1}$	$u_{1,1}$	$u_{2,1}$	$u_{3,1}$	$u_{4,1}$	$u_{x,1}$
	2	$u_{0,2}$	$u_{1,2}$	$u_{2,2}$	$u_{3,2}$	$u_{4,2}$	$u_{x,2}$
	3	$u_{0,3}$	$u_{1,3}$	$u_{2,3}$	$u_{3,3}$	$u_{4,3}$	$u_{x,3}$
	4	$u_{0,4}$	$u_{1,4}$	$u_{2,4}$	$u_{3,4}$	$u_{4,4}$	$u_{x,4}$
	y	$u_{0,y}$	$u_{1,y}$	$u_{2,y}$	$u_{3,y}$	$u_{4,y}$	$u_{x,y}$

Of which Table each horizontal column is a function of x only, y remaining the same in each term of the series; and each vertical column is a function of y only, y being the only variable, the value of x remaining the same throughout.

The difference between any of the successive terms of these vertical or horizontal series is found by the ordinary rules; but to show which quantity is the independent variable, the suffix x or y is added to the Δ . Thus Δ_x or Δ_y indicate that the difference is taken with regard to x or y .

Thus

$$u_{x+1,y} - u_{x,y} = \Delta_x \cdot u_{x,y} \quad \Delta_x u_{x+1,y} - \Delta_x u_{x,y} = \Delta_x^2 u_{x,y};$$

$$u_{y+1,x} - u_{y,x} = \Delta_y \cdot u_{x,y} \quad \Delta_y \cdot u_{y+1,x} - \Delta_y u_{x,y} = \Delta_y^2 u_{x,y}.$$

$\Delta_x \cdot u_{x,y}$ and $\Delta_y \cdot u_{x,y}$ are called the partial differences of $u_{x,y}$; but if x and y both vary at once the total difference of $u_{x,y}$, which is denoted by $\bar{\Delta} u_{x,y}$, is

$$\bar{\Delta} \cdot u_{x,y} = u_{x+1,y+1} - u_{x,y}.$$

(41.) By means of the partial differences, the general term of any of the columns may be found by the formulæ previously investigated; thus to find $u_{x,0}$, writing $u_{x,0}$ for u_x , and $u_{0,0}$ for u_0 , we have

$$u_{x,0} = u_{0,0} + x \Delta_x \cdot u_{0,0} + \frac{x \cdot x - 1}{1 \cdot 2} \Delta_x^2 u_{0,0} + \frac{x \cdot x - 1 \cdot x - 2}{1 \cdot 2 \cdot 3} \Delta_x^3 u_{0,0} + \&c.,$$

and

$$\Delta_x^2 u_{0,0} = u_{x,0} - x \cdot u_{x-1,0} + \frac{x \cdot x - 1}{1 \cdot 2} u_{x-2,0} - \frac{x \cdot x - 1 \cdot x - 2}{1 \cdot 2 \cdot 3} u_{x-3,0} + \&c.;$$

and to extend these formulæ to any column, as, for instance, to obtain $u_{x,y}$, we must write y for the second 0, and thus

VOL. II.

Calculus of
Finite
Differences.

$$u_{x,y} = u_{0,y} + x \Delta_x \cdot u_{0,y} + \frac{x \cdot x - 1}{1 \cdot 2} \Delta_x^2 u_{0,y} + \frac{x \cdot x - 1 \cdot x - 2}{1 \cdot 2 \cdot 3} \Delta_x^3 u_{0,y} + \&c.$$

Calculus of
Finite
Differences.

But, obviously, $u_{0,y} = u_{y,0}$; and, therefore, we have

$$u_{0,y} = u_{0,0} + y \cdot \Delta_y u_{0,0} + \frac{y \cdot y - 1}{2} \Delta_y^2 u_{0,0} + \frac{y \cdot y - 1 \cdot y - 2}{1 \cdot 2 \cdot 3} \Delta_y^3 u_{0,0} + \&c.$$

Let this value be substituted in the expression for $u_{x,y}$, so that $u_{x,y}$ may be a function of $u_{0,0}$, and of its partial differences; but in making this substitution we shall evidently meet with the following terms:

$$\Delta_x (\Delta_y \cdot u_{0,0}), \Delta_x^2 (\Delta_y \cdot u_{0,0}), \dots \text{and } \Delta_x^m (\Delta_y^n u_{0,0});$$

the last of which denotes n differentiations with regard to the index y , followed by m differentiations with regard to the index x , and which may be written $\Delta_{x,y}^{m+n} u_{0,0}$; and this notation being used, we have

$$\begin{aligned} u_{x,y} = u_{0,0} &+ \frac{x}{1} \Delta_x \cdot u_{0,0} + \frac{x \cdot x - 1}{2} \Delta_x^2 u_{0,0} + \frac{x \cdot x - 1 \cdot x - 2}{1 \cdot 2 \cdot 3} \Delta_x^3 u_{0,0} + \&c. \\ &+ \frac{y}{1} \Delta_y u_{0,0} + \frac{xy}{1 \cdot 1} \cdot \Delta_{x,y}^{1+1} u_{0,0} + \frac{y \cdot x \cdot x - 1}{1 \cdot 1 \cdot 2} \Delta_{x,y}^{2+1} u_{0,0} + \&c. \\ &+ \frac{y \cdot y - 1}{1 \cdot 2} \Delta_y^2 \cdot u_{0,0} + \frac{xy \cdot y - 1}{1 \cdot 1 \cdot 2} \Delta_{x,y}^{1+2} u_{0,0} + \&c. \\ &+ \frac{y \cdot y - 1 \cdot y - 2}{1 \cdot 2 \cdot 3} \Delta_y^3 u_{0,0} + \&c.; \end{aligned}$$

a formula which gives the general term of a function of x and y in terms of the first term $u_{0,0}$, and its partial differences.

(42.) It only remains to show how the terms which have the symbols Δ_x , or Δ_y , or $\Delta_{x,y}$ are to be found. Referring to the Table in the article which has just preceded, we shall, by first taking the differences of the series in the first horizontal line, and then in the second, and so on, have

$$\begin{array}{llll} u_{0,0}, & \Delta_x u_{0,0}, & \Delta_x^2 u_{0,0}, & \Delta_x^3 u_{0,0}, \&c. \dots \text{when } y = 0 \\ u_{0,1}, & \Delta_x u_{0,1}, & \Delta_x^2 u_{0,1}, & \Delta_x^3 u_{0,1}, \&c. \dots \text{when } y = 1 \\ u_{0,2}, & \Delta_x u_{0,2}, & \Delta_x^2 u_{0,2}, & \Delta_x^3 u_{0,2}, \&c. \dots \text{when } y = 2 \\ u_{0,3}, & \Delta_x u_{0,3}, & \Delta_x^2 u_{0,3}, & \Delta_x^3 u_{0,3}, \&c. \dots \text{when } y = 3 \\ \&c. & \&c. & \&c. & \&c. \end{array}$$

Now subtract the first line from the second, the second from the third, &c., and the remainders will express the differences with regard to y , and these will be

$$\begin{array}{llll} \Delta_y \cdot u_{0,0}, & \Delta_{x,y}^{1+1} u_{0,0}, & \Delta_{x,y}^{2+1} u_{0,0}, & \Delta_{x,y}^{3+1} u_{0,0}, \&c. \dots \text{when } y = 0 \\ \Delta_y \cdot u_{0,1}, & \Delta_{x,y}^{1+1} u_{0,1}, & \Delta_{x,y}^{2+1} u_{0,1}, & \Delta_{x,y}^{3+1} u_{0,1}, \&c. \dots \text{when } y = 1 \\ \Delta_y \cdot u_{0,2}, & \Delta_{x,y}^{1+1} u_{0,2}, & \Delta_{x,y}^{2+1} u_{0,2}, & \Delta_{x,y}^{3+1} u_{0,2}, \&c. \dots \text{when } y = 2. \end{array}$$

Subtracting again the first line from the second, and the second from the third, &c., the remainders will be the second differences with regard to y ; and thus there will arise

$$\begin{array}{llll} \Delta_y^2 u_{0,0}, & \Delta_{x,y}^{1+2} u_{0,0}, & \Delta_{x,y}^{2+2} u_{0,0}, & \&c. \dots \text{when } y = 0 \\ \Delta_y^2 u_{0,1}, & \Delta_{x,y}^{1+2} u_{0,1}, & \Delta_{x,y}^{2+2} u_{0,1}, & \&c. \dots \text{when } y = 1; \end{array}$$

and similarly we may arrive at any order of differences.

As an example, let the following numbers be placed instead of the values of $u_{0,0}$, $u_{0,1}$, &c.; viz.

5	6	9	14	21	&c.
8	11	16	23	32	&c.
17	22	29	38	49	&c.
32	39	48	59	72	&c.
&c.	&c.				

then, by the application of the preceding reasoning, we shall form the following Table:

First Group.	Second Group.	Third Group.	Fourth Group.
5, 1, 2, 0			
8, 3, 2, 0	3, 2, 0		
17, 5, 2, 0	9, 2, 0	6, 0	
32, 7, 2, 0	15, 2, 0	6, 0	0

$$\begin{aligned} \therefore u_{0,0} &= 5, & \Delta_x u_{0,0} &= 1, & \Delta_x^2 u_{0,0} &= 2, & \Delta_x^3 u_{0,0} &= 0 \\ & & \Delta_y u_{0,0} &= 3, & \Delta_{x,y}^{1+1} u_{0,0} &= 2, & \Delta_{y,x}^{1+2} u_{0,0} &= 0 \\ & & & & \Delta_y^2 u_{0,0} &= 6, & \Delta_{x,y}^{1+2} u_{0,0} &= 0 \\ & & & & & & \Delta_y^3 u_{0,0} &= 0 \end{aligned}$$

$$\begin{aligned} \therefore u_{x,y} &= 5 + x + \frac{x \cdot x - 1}{2} \cdot 2 + 3y + xy \cdot 2 + \frac{y \cdot y - 1}{2} \cdot 6 \\ &= 5 + x^2 + 2xy + 3y^2, \end{aligned}$$

the general value, and by which the table of numbers given may be formed, and their values extended.
(43.) We shall now find the expression for the total differences of a function of any number of variables in terms of its partial differences.

Let $u_{x,y}$ be any function of x and y , and, in the first instance, let x alone vary, then the new state of the function will be represented by $u_{x,y} + \Delta_x \cdot u_{x,y}$; but if now we suppose y also to vary, and if $u'_{x,y}$ represent what $u_{x,y}$ becomes

$$u'_{x,y} = u_{x,y} + \Delta_x u_{x,y} + \Delta_y \cdot (u_{x,y} + \Delta_x \cdot u_{x,y}) = u_{x,y} + \Delta_x u_{x,y} + \Delta_y u_{x,y} + \Delta_y \Delta_x u_{x,y}$$

Again, if u be a function of three variables, as x, y, z , then supposing x and y to vary while z remains constant, the function will become as we have just seen,

$$= u + \Delta_x u + \Delta_y \cdot u + \Delta_y \cdot \Delta_x u;$$

and, therefore, when z varies, we have

$$\begin{aligned} u' &= u + \Delta_x u + \Delta_y u + \Delta_y \cdot \Delta_x u + \Delta_x \cdot (u + \Delta_x u + \Delta_y u + \Delta_y \cdot \Delta_x u) \\ &= u + \Delta_x u + \Delta_y u + \Delta_x \Delta_y u + \Delta_y \cdot \Delta_x u + \Delta_x \Delta_x u + \Delta_x \Delta_y u + \Delta_x \cdot \Delta_y \cdot \Delta_x u; \end{aligned}$$

and the process may be thus extended to any number of variables; but the method of separating the symbols of quantity from those of operation enables us to dispense with any further direct investigations.

For if $u_{x,y}$ be a function of two variables, since

$$1 + \Delta_x + \Delta_y + \Delta_x \Delta_y = (1 + \Delta_x)(1 + \Delta_y);$$

$\therefore u'_{x,y} = (1 + \Delta_x) \cdot (1 + \Delta_y) u_{x,y}$, and $\therefore \Delta u_{x,y} = u'_{x,y} - u_{x,y} = (1 + \Delta_x \cdot 1 + \Delta_y - 1) u_{x,y}$, where $\Delta u_{x,y}$ expresses the total difference.

$$\text{Again, } \therefore 1 + \Delta_x + \Delta_y + \Delta_x \Delta_y + \Delta_x \Delta_x + \Delta_x \Delta_y + \Delta_x \Delta_x \Delta_y = \overline{1 + \Delta_x} \overline{1 + \Delta_y} \overline{1 + \Delta_x};$$

$$\text{and } \therefore \text{if } u = f(x, y, z); \quad u' = \overline{1 + \Delta_x} \cdot \overline{1 + \Delta_y} \cdot \overline{1 + \Delta_z} u;$$

$$\therefore \Delta u = \{ \overline{1 + \Delta_x} \cdot \overline{1 + \Delta_y} \cdot \overline{1 + \Delta_z} - 1 \} u.$$

(44.) Next to find the second difference, change u into Δu .

$$\begin{aligned} \therefore \Delta^2 u_{x,y} &= \Delta_x \Delta u_{x,y} + \Delta_y \cdot \Delta u_{x,y} + \Delta_y \Delta_x \cdot \Delta u_{x,y} \\ &= (\Delta_x + \Delta_y + \Delta_y \Delta_x) \Delta u_{x,y} \\ &= \{ \overline{1 + \Delta_x} \cdot \overline{1 + \Delta_y} - 1 \} \Delta u_{x,y} \\ &= \{ \overline{1 + \Delta_x} \overline{1 + \Delta_y} - 1 \}^2 \cdot u_{x,y}; \end{aligned}$$

and, similarly,

$$\Delta^n u_{x,y} = \{ \overline{1 + \Delta_x} \cdot \overline{1 + \Delta_y} - 1 \}^n u_{x,y}.$$

The expression for $\Delta^2 u_{x,y}$ may be found by substituting for $\Delta u_{x,y}$ its value, and the truth of the above reasoning rendered at once evident.

We may obviously extend the formulæ proved for two variables to functions containing any number, and thus have

$$\Delta^n u = \{ \overline{1 + \Delta_x} \overline{1 + \Delta_y} \overline{1 + \Delta_z} \dots - 1 \}^n u.$$

(45.) The preceding expressions for $\Delta^n u$ may be put under another and remarkable form, by means of the equation deduced in Article 34.

We there see that, by separating the symbols, since $(e^{\frac{d}{dx}} - 1) u_x$ produces the series which is equivalent to Δu_x , it may be written for Δu_x .

Hence for $1 + \Delta_x, 1 + \Delta_y$, we may write $e^{\frac{d}{dx}}, e^{\frac{d}{dy}}$; and thus, if $u_{x,y}$ represent a function of two variables,

$$\Delta^n u_{x,y} = (e^{\frac{d}{dx} + \frac{d}{dy}} - 1)^n u_{x,y};$$

and, similarly,

$$\Delta^n u_{x,y,z,\dots} = (e^{\frac{d}{dx} + \frac{d}{dy} + \frac{d}{dz} + \dots} - 1)^n u_{x,y,z,\dots}$$

(46.) We may observe with regard to these expressions for $\Delta^n u$, and for the sake of illustration referring solely to the more simple case, where

$$\Delta^n u_{x,y} = (e^{\frac{d}{dx} + \frac{d}{dy}} - 1)^n u_{x,y}$$

Calculus of
Finite
Differences.

that no confusion can arise from the powers of $\frac{d}{dx}$ and $\frac{d}{dy}$ when expanded, if we keep in mind their peculiar signification: and observe that any such term as $\frac{d^p}{dx^p} \times \frac{d^q}{dy^q} \cdot u_{x,y}$ is nothing more than $\frac{d^{p+q} u_{x,y}}{dx^p \cdot dy^q}$.

Calculus of
Finite
Differences.

The coefficient of this general term may be thus found. Let t and t_1 be written for $\frac{d}{dx}$ and $\frac{d}{dy}$, then the coefficients of the expansion of $\Delta^n u_{x,y}$ will be the same as those of $(e^{t+t_1} - 1)^n$, and the coefficient of $\frac{d^{p+q} u_{x,y}}{dx^p \cdot dy^q}$ will be the same as that of $t^p \cdot t_1^q$.

But such a term as $t^p \cdot t_1^q$ must arise from the expansion of $(t + t_1)^{p+q}$, and by the binomial theorem the coefficient of $t^p \cdot t_1^q$

$$= \frac{(p+q)(p+q-1)\dots p+1}{1 \cdot 2 \dots q} \cdot \frac{p+1}{1 \cdot 2 \dots p} = \frac{1 \cdot 2 \cdot 3 \dots p+q}{1 \cdot 2 \cdot 3 \dots q \times 1 \cdot 2 \cdot 3 \dots p}.$$

But by Article 39 the coefficient of $(t + t_1)^{p+q}$

$$= \frac{\Delta^n \cdot 0^{p+q}}{1 \cdot 2 \cdot 3 \dots p+q};$$

and, therefore, the coefficient of $t^p \cdot t_1^q$, or of $\frac{d^{p+q} u_{x,y}}{dx^p \cdot dy^q}$, will be

$$\frac{\Delta^n \cdot 0^{p+q}}{1 \cdot 2 \cdot 3 \dots p+q} \times \frac{1 \cdot 2 \cdot 3 \dots p+q}{1 \cdot 2 \cdot 3 \dots p \times 1 \cdot 2 \dots q} = \frac{\Delta^n \cdot 0^{p+q}}{1 \cdot 2 \cdot 3 \dots p \times 1 \cdot 2 \cdot 3 \dots q}.$$

Interpolations.

(47.) One of the most important applications of the theory of Finite Differences is to the subject of interpolations, or the method of inserting between the terms of a series some new term or terms subject to the same law.

The general equation

$$u_x = u + x \cdot \Delta u + \frac{x \cdot x - 1}{2} \Delta^2 u + \frac{x \cdot x - 1 \cdot x - 2}{1 \cdot 2 \cdot 3} \Delta^3 u + \&c.$$

will always give us any term we may wish of the series of terms, $u, u_1, u_2, u_3, \dots, u_n$, when u and its successive differences, as well as x , are given: but it frequently happens that only a few of these terms are known; and then the result which we obtain, although satisfying the given conditions, cannot be said to be the only one that possesses this property, and thus the problem is an indeterminate one.

(48.) Thus, if we wish to find an algebraical expression which, by giving particular values to x , as 0, 1, 2, shall not only produce the numbers 3, 7, 19, but others in successive order, so as to form a series of which these numbers shall be the first three terms, let us assume that the second differences are constant.

Then

$$\therefore u = 3, \quad \Delta u = 4, \quad \Delta^2 u = 8,$$

$$u_x = 3 + 4x + \frac{x \cdot x - 1}{2} \cdot 8 = 3 + 4x + 4x^2 - 4x = 3 + 4x^2.$$

And now, if we give to x the values 0, 1, 2, 3, 4, &c., a series will arise of which the first three terms will be the given numbers, and of which the second differences are constant. But had we at once assumed $u_x = A + Bx + Cx^2$, and determined the constants A, B, C by the three given conditions of u being successively equal to the numbers 3, 7, 19 when $x = 0, 1, 2$, we shall find that $u_x = 3 + \frac{8}{3}x + \frac{4}{3}x^2$, which will give the very different series 3, 7, 19, 47, 99, &c., and of which the third differences are constant.

(49.) This example thus plainly shows the truth of the assertion, that the problem of interpolations is indeterminate; but it may be further illustrated by the nature of a curve. For considering u_x to be the general expression for the ordinate of an unknown curve, of which $n+1$ values at given intervals are known, it is plainly impossible to find the nature of the curve itself from these conditions, since it is easily to be conceived that innumerable curves may pass through the $n+1$ points, and yet in every other particular differ widely from each other.

But if it be required to find the nature of the curve at some one point lying between two given points, and if we can assume this required point to be very near one of the given ordinates, the chance of error is much lessened.

Now this will come to the same thing, if we expand the expression

$$u_x = u + x \cdot \Delta u + \frac{x \cdot x - 1}{2} \Delta^2 u + \&c.$$

according to the powers of x , when we shall have

$$u_x = u + Ax + Bx^2 + Cx^3 + \&c. \dots + Nx^n;$$

Calculus of Finite Differences. and assume this value of u_x to represent the true ordinate of the curve. The curve thus assumed is of the parabolic species, and if not the one that we are in quest of, is at least of as simple a form, and may have an osculation of the n th order with it.

Calculus of Finite Differences.

When, therefore, we have to interpolate a series within very narrow limits, which is the case alluded to in the preceding illustration, we may assume for the general term an expression developed according to the positive powers of its index, and neglecting all the powers beyond a certain limit, which limit the number of given values will indicate, the general term is known.

(50.) A simple instance of interpolation is given by the question, to place a mean between two terms of the arithmetic series $a, a + b, a + 2b, a + 3b, \&c.$

Then, if it be required to find a term between $a + 2b$ and $a + 3b$, which is also equidistant from either of them,

making

$$u = a + 2b, u_1 = a + 3b; \therefore \Delta \cdot u = b \text{ and } x = \frac{1}{2};$$

$$\therefore u_x = u + x \Delta \cdot u = a + 2b + \frac{b}{2} = a + \frac{5b}{2}.$$

This question may be otherwise solved. For since two terms are given, and the intermediate one required, we may state it, that u and u_2 are given, and u_1 required.

Here we assume

$$\Delta^2 \cdot u = 0; \text{ and } \therefore u_2 - 2u_1 + u = 0; \therefore u_1 = \frac{u + u_2}{2};$$

from which we have the same result as before.

(51.) In general, when it is required to find any one term of the series $u, u_1, u_2, u_3 \dots u_n$, and the rest are given, we may assume that $\Delta^n u = 0$, or that the $(n - 1)$ th differences are constant. For this supposition will obviously give a term which will satisfy the conditions of the problem. In this case we have the simple equation

$$u_n - n u_{n-1} + \frac{n n - 1}{2} u_{n-2} - \frac{n n - 1 n - 2}{1 \cdot 2 \cdot 3} u_{n-3} + \&c. = 0,$$

from which the required term may be found.

Example. Given three values, u, u_1, u_3 , of any function, insert the deficient one u_2 .

Here we make

$$\Delta^3 u = 0; \therefore u_3 - 3u_2 + 3u_1 - u = 0;$$

$$\therefore u_2 = \frac{u_3 + 3u_1 - u}{3};$$

and having found u_2 , we can then find Δu and $\Delta^2 u$, and thus determine $u_x = u + x \Delta u + \frac{x x - 1}{2} \Delta^2 u$, and obtain the general law of the series.

Example 2. Given

$$u = 3, u_1 = 7, u_3 = 39;$$

$$\therefore u_2 = \frac{39 + 21 - 3}{3} = 19;$$

$$\therefore \Delta \cdot u = 4, \Delta^2 \cdot u = 8, \text{ and } u_x = 3 + 4x^2.$$

(52.) Again, when two terms are deficient, let the series of terms be

$$u, u_1, u_2, u_3 \dots u_n, u_{n+1};$$

and here we may make $\Delta^n \cdot u = 0$ and $\Delta^n \cdot u_1 = 0$, whence we have

$$u_n - n u_{n-1} + \frac{n n - 1}{2} u_{n-2} - \frac{n n - 1 n - 2}{1 \cdot 2 \cdot 3} u_{n-3} + \&c. = 0,$$

and

$$u_{n+1} - n u_n + \frac{n n - 1}{2} u_{n-1} - \frac{n n - 1 n - 2}{1 \cdot 2 \cdot 3} u_{n-2} + \&c. = 0;$$

from which two simple equations the unknown term may be found.

Thus, if there be given u, u_1, u_4, u_5 , and u_2, u_3 be required, assume

$$\Delta^4 u = 0 \text{ and } \Delta^4 u_1 = 0;$$

and

$$\therefore u_4 - 4u_3 + 6u_2 - 4u_1 + u = 0,$$

whence

$$u_5 - 4u_4 + 6u_3 - 4u_2 + u_1 = 0;$$

and

$$u_2 = \frac{-3u + 10u_1 + 5u_4 - 2u_5}{10},$$

$$u_3 = \frac{-2u + 5u_1 + 10u_4 - 3u_5}{10};$$

Calculus of and having got these terms we may interpolate any intermediate term whatever by means of the formula

Finite
Differences.

$$u_x = u + x \cdot \Delta \cdot u + \frac{x(x-1)}{2} \cdot \Delta^2 \cdot u + \&c.$$

Calculus of
Finite
Differences.

(53.) Of the use of this formula we will take an example from a table of logarithms, and which with some alterations is the illustration made use of by Lacroix.

Then let it be required to find the logarithm of 314.15926536, having given the logarithm of the equidistant numbers 314, 315, 316, 317, and 318.

In this example the logarithms will be represented by the function u_x , and the numbers by x ; then, calling $u = \log 314$, $u_1 = \log 315$, &c., and omitting the common characteristic, we may form the Table

	Numbers.	Logarithms.	Δu .	$\Delta^2 u$.	$\Delta^3 u$.	$\Delta^4 u$.
u	314	.4969296481				
u_1	315	.4983105538	13809057			
u_2	316	.4996870826	13765288	-43769		
u_3	317	.5010592622	13721796	-43492	+277	
u_4	318	.5024271200	13678578	-43218	+274	-3

after which the differences continue to decrease.

Hence from the Table above we have

$$u_x = u + x \Delta u + \frac{x \cdot x - 1}{2} \Delta^2 u + \frac{x \cdot x - 1 \cdot x - 2}{1 \cdot 2 \cdot 3} \Delta^3 u + \frac{x \cdot x - 1 \cdot x - 2 \cdot x - 3}{1 \cdot 2 \cdot 3 \cdot 4} \Delta^4 u,$$

and

$$u = .4969296481$$

$$\Delta u = .0013809057 \quad \Delta^2 u = -.0000043769$$

$$\Delta^3 u = .0000000277 \quad \Delta^4 u = -.0000000003;$$

$$x = .15926536; \frac{x-1}{2} = \frac{x}{2} - \frac{1}{2} = \frac{x}{2} - .5 = -.42036732$$

$$\frac{x-2}{3} = \frac{x}{3} - \frac{2}{3} = -.61357821; \quad \frac{x-3}{4} = \frac{x}{4} - \frac{3}{4} = -.71018366;$$

and these values being substituted in the series for u_x , we find, at length,

$$u_x = \log 314.15926536 = 2.4971498726; \therefore \log \pi = .4971498726.$$

(54.) It is a common problem to insert between two numbers of a given series of numbers any number of equidistant numbers which may follow a law that will comprise not only themselves but also the given numbers.

By such means the tables of logarithms are greatly extended, and the idea of it first appears to have occurred to Briggs.

The following method, remarkable for its simplicity, was given by Mouton in 1670, and by means of it the required terms are computed by addition only.

The principle upon which it is founded is this: first ascertain at what order of the differences of the given numbers the differences become constant; then it is assumed that the series formed by the interpolation of the new terms will have the same order of differences constant.

As an example, let the series be

$$0, 15, 41, 87, 162, 275, \&c.,$$

where $\Delta u_0 = 15$, $\Delta^2 u_0 = 11$, $\Delta^3 u_0 = 9$, $\Delta^4 u_0 = 0$, or the third differences are constant, and it is required to insert two new terms between every two consecutive terms of the given series.

Now making the first term of the series a , the first difference of the series, b , the second difference, c , and the third, d ; let us form the annexed Table according to the principles explained in the introductory articles.

	Numbers.	First Differences.	Second Differences.	Third Differences.
u_0	a			
u_1	$a + b$	b		
u_2	$a + 2b + c$	$b + c$	c	
u_3	$a + 3b + 3c + d$	$b + 2c + d$	$c + d$	d
u_4	$a + 4b + 6c + 4d$	$b + 3c + 3d$	$c + 2d$	d
u_5	$a + 5b + 10c + 10d$	$b + 4c + 6d$	$c + 3d$	d
u_6	$a + 6b + 15c + 20d$	$b + 5c + 10d$	$c + 4d$	d
u_7	$a + 7b + 21c + 35d$	$b + 6c + 15d$	$c + 5d$	d
u_8	$a + 8b + 28c + 56d$	$b + 7c + 21d$	$c + 6d$	d
u_9	$a + 9b + 36c + 84d$	$b + 8c + 28d$	$c + 7d$	d

Calculus of
Finite
Differences.

Calculus of
Finite
Differences.

Now, in the example which we have taken, the terms u_0, u_3, u_6 , and u_9 are known, or four equations are given, by which the four unknown quantities a, b, c, d may be determined.

Thus

$$u_0 = a = 0, \quad u_3 = a + 3b + 3c + d = 15,$$

and

$$u_6 = a + 6b + 15c + 20d = 41, \quad \text{and} \quad u_9 = a + 9b + 36c + 84d = 87,$$

and

$$\therefore u_6 - 2u_3 = 11 = 9c + 18d,$$

whence

$$u_9 - 3u_3 = 42 = 27c + 81d;$$

$$d = \frac{1}{3}, \quad c = \frac{5}{9}, \quad \text{and} \quad b = 5 - c - \frac{d}{3} = \frac{13}{3};$$

and from these values the successive terms of the series may be found.

It may be observed that the value of the third difference in the original series is 9, while in the interpolated one it is $\frac{1}{3} = \frac{9}{27} = \frac{9}{3^3}$, or if $D^3 u_0$ and $\Delta^3 u_0$ represent these differences, $D^3 u_0 = 3^3 \cdot \Delta^3 u_0$.

(55.) We proceed to give a general solution of this problem. Let the number of given terms be $n + 1$; and let it be required to insert $m - 1$ terms between each pair of the terms of the original series; as, for instance, between u_x and u_{x+1} .

Now, the general value for u_x is when $\Delta^n u_0$ is constant:

$$u_x = u_0 + x \cdot \Delta u_0 + \frac{x(x-1)}{2} \cdot \Delta^2 u_0 + \frac{x(x-1)(x-2)}{1 \cdot 2 \cdot 3} \cdot \Delta^3 u_0 + \&c. \\ + \frac{x(x-1)(x-2) \dots (x-n+1)}{1 \cdot 2 \cdot 3 \dots n} \cdot \Delta^n u_0;$$

and since there are to be $m - 1$ terms between u_x and u_{x+1} , we must suppose unity to be divided into m parts, each $= \frac{1}{m}$, so that x may increase each time by $\frac{1}{m}$; and $\therefore$ after (t) times x will be increased by $\frac{t}{m}$; or, supposing the original value of x to be zero, x may $= \frac{t}{m}$, and $\therefore$

$$u_x = u_0 + \frac{t}{m} \cdot \Delta u_0 + \frac{t \cdot t - m}{1 \cdot 2 m^2} \Delta^2 u_0 + \frac{t \cdot t - m \cdot t - 2m}{1 \cdot 2 \cdot 3 m^3} \Delta^3 u_0 + \&c. \\ + \frac{t \cdot (t - m) (t - 2m) \dots (t - n - 1 m)}{1 \cdot 2 \cdot 3 \dots n \cdot m^n} \cdot \Delta^n u_0.$$

Let the successive differences of this equation be taken; and since, in every algebraical function having positive indices the differences vanish when their order is greater than the index of the variable, we have

$$\Delta^r u_x = \frac{\Delta^r \cdot t \cdot (t - m) (t - 2m) \dots (t - r - 1 m)}{1 \cdot 2 \cdot 3 \dots r \cdot m^r} \Delta^r u_0 \\ + \frac{\Delta^r \cdot t \cdot (t - m) (t - 2m) \dots (t - r m)}{1 \cdot 2 \cdot 3 \dots (r + 1) m^{r+1}} \cdot \Delta^{r+1} u_0 \\ + \&c. \\ + \frac{\Delta^r \cdot t \cdot (t - m) (t - 2m) \dots (t - n - 1 \cdot r)}{1 \cdot 2 \cdot 3 \dots n \cdot m^n} \Delta^n u_0.$$

The terms $\Delta u_0, \Delta^2 u_0$, and $\Delta^n u_0$ are constant, and the symbol Δ' indicates that the differences with regard to x increase by $\frac{1}{m}$.

And now having performed the differentiations, and then made $t = 0$, and having given to r the values 1, 2, 3, &c., we shall find the differences that we are in search of and thus solve the problem which has been proposed, or if we take as an illustration the example in the preceding article, we shall be able to find the differences b, c, d ; and the formulæ for u_x in that particular example will be

$$u_x = u_0 + \frac{t}{3} \Delta u_0 + \frac{t \cdot t - 3}{1 \cdot 2 \cdot 3^2} \Delta^2 u_0 + \frac{t \cdot t - 3 \cdot t - 6}{1 \cdot 2 \cdot 3 \cdot 3^3} \Delta^3 u_0;$$

whence it is obvious, since $\Delta^3 (t \cdot t - 3 \cdot t - 6) = \Delta^3 \cdot t^3 = 1 \cdot 2 \cdot 3$, that $\Delta^3 u_0 = \frac{1}{3^3} \Delta^3 u_0$, an equation which has been previously noticed.

If, however, in the general value for $\Delta^r u_x$, we arrange the terms according to the powers of t , and since

we have $t \cdot (t - m) (t - 2m) (t - 3m) \dots (t - r - 1 \cdot m) = t^r + A m t^{r-1} + B m^2 t^{r-2} + \&c.$,

Calculus of
Finite
Differences.

$$\begin{aligned}\Delta^r \cdot (t^r + A m t^{r-1} + B m^2 t^{r-2} + \&c.) &= \Delta^r \cdot t^r \\ \Delta^r (t^{r+1} + A_1 m t^r + B_1 m^2 t^{r-1} + \&c.) &= \Delta^r \cdot t^{r+1} + A_1 m \Delta^r t^r \\ \Delta^r (t^{r+2} + A_2 m t^{r+1} + B_2 m^2 t^r + \&c.) &= \Delta^r \cdot t^{r+2} + A_2 m \Delta^r t^{r+1} + B_2 m^2 \cdot \Delta^r \cdot t^r \\ &\&c.;\end{aligned}$$

Calculus of
Finite
Differences.

or writing $\alpha, \beta, \gamma, \&c.$ for $\Delta^r \cdot t^r, \Delta^r \cdot t^{r+1}, \Delta^r \cdot t^{r+2}, \&c.$, we have

$$\Delta^r u_x = \frac{1}{1 \cdot 2 \cdot 3 \dots r \cdot m^r} \left\{ \alpha \Delta^r u_0 + \frac{\beta + \alpha A_1 m}{(r+1)m} \Delta^{r+1} u_0 + \frac{\gamma + A_2 m \beta + B_2 m^2 \alpha}{(r+1)(r+2)m^2} \Delta^{r+2} u_0 + \&c. \right\}$$

Let
and

$$r = n, \therefore \alpha = 1 \cdot 2 \cdot 3 \dots n, \Delta^{n+1} u_0 = 0, \Delta^{n+2} u_0 = 0, \&c.,$$

$$\Delta^n u_0 = \frac{\Delta^n u_0}{m^n},$$

which, when $m = n = 3$, is the theorem to which we have been led in the last article by mere inspection.

(56.) Next let it be required to find the index (x), to which, in a series of given numbers, a number included between two terms of this series belongs. Such is the problem when there is given a logarithm not found in the tables, and the corresponding number is to be sought.

The problem is not difficult when the values of $\Delta u_0, \Delta^2 u_0, \Delta^3 u_0, \&c.$ are very convergent; for then, in the equation

$$u_x = u_0 + x \Delta u_0 + \frac{x(x-1)}{2} \Delta^2 u_0 + \frac{x(x-1)(x-2)}{1 \cdot 2 \cdot 3} \Delta^3 u_0 + \&c.,$$

u_x is given and x is to be found.

If $\Delta^2 u_0$ be very much smaller than $\Delta \cdot u_0$, we may as a first approximation neglect $\Delta^2 u_0$, and make $u_x = u_0 + x \cdot \Delta u_0$; whence

$$x = \frac{u_x - u_0}{\Delta u_0}.$$

Call this value (α), and then substituting (α) for x , and stopping at the second difference,

$$u_x - u_0 = x \left(\Delta u_0 + \frac{\alpha - 1}{2} \Delta^2 u_0 \right); \therefore x = \frac{u_x - u_0}{\Delta u_0 + \frac{\alpha - 1}{2} \Delta^2 u_0};$$

and calling this value of x, β , and then include the third differences, we shall successively approximate more nearly to the true value of x .

When, however, the differences do not decrease so rapidly as to allow us to neglect the second, third, &c. differences, we must stop at the first very small term, and determine x by the solution of an equation, the dimensions of which will be the last order of differences which we retain; thus if $\Delta^4 u_0$ may be neglected, x must be found by means of the cubic equation

$$u_x - u_0 = \left(\Delta u_0 - \frac{1}{2} \Delta^2 u_0 + \frac{1}{3} \Delta^3 u_0 \right) x + \frac{1}{2} (\Delta^2 u_0 - \Delta^3 u_0) x^2 + \frac{x^3 \cdot \Delta^3 u_0}{6}.$$

(57.) As an illustration, let us take the following question proposed in Herschell's examples.

Three observations of a certain quantity were taken at equal intervals. The values were u_0, u_1, u_2 ; between which its value was a . When did this happen?

Here $u_x = a$ is given, and x is required.

Assuming $\Delta^3 u_0 = 0$,

$$u_0 + x \Delta u_0 + \frac{x(x-1)}{2} \Delta^2 u_0 = a;$$

$$\therefore \Delta^2 u_0 \cdot x^2 + (2 \Delta u_0 - \Delta^2 u_0) x = 2(a - u_0);$$

$$\therefore x = \frac{1}{2 \Delta^2 u_0} \{ \Delta^2 u_0 - 2 \Delta u_0 + \sqrt{(\Delta^2 u_0 - 2 \Delta u_0)^2 + 8(a - u_0) \Delta^2 u_0} \}.$$

If $\Delta^2 u_0 = 0$, or be so small as to be neglected, we have, from the original quadratic,

$$x = \frac{2(a - u_0)}{2 \Delta u_0} = \frac{a - u_0}{u_1 - u_0}.$$

Next to find the value of x , when $\Delta^2 u_0$, although small, must not be neglected, yet its square and higher powers may be omitted: we must first expand the value of x obtained above according to the powers of $\Delta^2 u_0$, and finally retain the first power only.

Now make

$$m = \Delta^2 u_0, n = \Delta u_0, \text{ and } c = a - u_0.$$

Then

$$\begin{aligned}x &= \frac{1}{2m} \cdot (m - 2n + \sqrt{(m - 2n)^2 + 8cm}) \\ &= \frac{1}{2m} \cdot \left(m - 2n + 2n \sqrt{1 - \frac{m}{n} + \frac{2cm}{n^2} + \frac{m^2}{4n^2}} \right)\end{aligned}$$

$$\begin{aligned}
 &= \frac{1}{2m} \cdot \left\{ m - 2n + 2n \left(1 - \frac{m}{2n} + \frac{cm}{n^2} + \frac{m^2}{8n^2} - \frac{1}{8} \cdot \frac{m^2}{n^2} \cdot \left(1 - \frac{2c}{n} \right)^2 \right) \right\} \\
 &= \frac{1}{2m} \cdot \left\{ m - 2n + 2n - m + \frac{2cm}{n} + \frac{m^2}{4n} - \frac{m^2}{4n} \left(1 - \frac{4c}{n} + \frac{4c^2}{n^2} \right) \right\} \\
 &= \frac{c}{n} + \frac{cm}{2n^2} - \frac{mc^2}{2n^3} = \frac{c}{n} + \frac{mc \cdot (n-c)}{2n^3} \\
 &= \frac{a - u_0}{\Delta \cdot u_0} + \frac{(a - u_0)(u_1 - a) \cdot \Delta^2 u_0}{2(\Delta \cdot u_0)^3};
 \end{aligned}$$

the latter term may $\therefore$ be considered as a correction to the value of a found on the supposition of $\Delta^2 u_0 = 0$.

(58.) Hitherto it has been supposed that the differences between the values of the variable x are equal; but, as in the application of this theory to practical questions this is not found to be the case, it is necessary to have formulæ which are not thus restricted. We then assume the general term of the series to be represented by a function of x , the powers of which are integral: the reasons for this assumption we have already given. Assuming then

$$u_x = A + Bx + Cx^2 + Dx^3 + \&c. + Nx^n,$$

and supposing that u_x becomes successively $u, u_1, u_2, u_3, \&c.$, when $a, a_1, a_2, a_3, \&c.$ are put for x , there will result the following $(n+1)$ equations to determine the $(n+1)$ quantities $A, B, C, D, \&c. N$:

$$\begin{aligned}
 u &= A + Ba + Ca^2 + Da^3 + \&c. + Na^n \\
 u_1 &= A + Ba_1 + Ca_1^2 + Da_1^3 + \&c. + Na_1^n \\
 u_2 &= A + Ba_2 + Ca_2^2 + Da_2^3 + \&c. + Na_2^n \\
 u_3 &= A + Ba_3 + Ca_3^2 + Da_3^3 + \&c. + Na_3^n \\
 \&c. &= \&c.
 \end{aligned}$$

Subtract the first line from the second, the second from the third, the third from the fourth, and so on in order; and then divide the results respectively by $a_1 - a, a_2 - a_1, a_3 - a_2, a_4 - a_3, \&c.$, and we have

$$\begin{aligned}
 \frac{u_1 - u}{a_1 - a} &= B + C(a_1 + a) + D(a_1^2 + a_1a + a^2) + \&c. \\
 \frac{u_2 - u_1}{a_2 - a_1} &= B + C(a_2 + a_1) + D(a_2^2 + a_2a_1 + a_1^2) + \&c. \\
 \frac{u_3 - u_2}{a_3 - a_2} &= B + C(a_3 + a_2) + D(a_3^2 + a_3a_2 + a_2^2) + \&c. \\
 \&c. &= \&c.;
 \end{aligned}$$

or making, after Laplace,

$$\frac{u_1 - u}{a_1 - a} = \delta u, \quad \frac{u_2 - u_1}{a_2 - a_1} = \delta u_1, \quad \frac{u_3 - u_2}{a_3 - a_2} = \delta u_2, \quad \&c.,$$

we have

$$\begin{aligned}
 \delta u &= B + C(a_1 + a) + D(a_1^2 + a_1a + a^2) + \&c. \\
 \delta u_1 &= B + C(a_2 + a_1) + D(a_2^2 + a_2a_1 + a_1^2) + \&c. \\
 \delta u_2 &= B + C(a_3 + a_2) + D(a_3^2 + a_3a_2 + a_2^2) + \&c.
 \end{aligned}$$

Subtracting these results in the same way as we have done for the values of $\delta u, \delta u_1, \delta u_2, \&c.$, and dividing the respective results by $a_2 - a, a_3 - a_1, \&c.$, and then writing $\delta^2 u, \delta^2 u_1, \&c.$ instead of the fractions $\frac{\delta u_1 - \delta u}{a_2 - a}, \frac{\delta u_2 - \delta u_1}{a_3 - a_1}, \&c.$, in conformity with the notation used in the preceding equations, we have

$$\begin{aligned}
 \delta^2 u &= C + D(a_2 + a_1 + a) + \&c. \\
 \delta^2 u_1 &= C + D(a_3 + a_2 + a_1) + \&c. \\
 \&c. &= \&c.
 \end{aligned}$$

Again subtracting these equations, and dividing the results by $a_3 - a, a_4 - a_1, \&c.$, and making

$$\frac{\delta^2 u_1 - \delta^2 u}{a_3 - a} = \delta^3 u, \quad \frac{\delta^2 u_2 - \delta^2 u_1}{a_4 - a_2} = \delta^3 u_1, \quad \&c. \dots$$

we shall have

$$\delta^3 u = D + \&c.$$

The method of obtaining the equations by which the $n+1$ quantities $A, B, C, \&c. N$ are to be found can now present no difficulty; yet as the calculations would be laborious when the expression for u_x contains many terms, we will stop at the fourth term Dx^3 , or assume that $u_x = A + Bx + Cx^2 + Dx^3$, we shall then have,

$$\begin{aligned}
 D &= \delta^3 u \\
 C &= \delta^2 u - (a_2 + a_1 + a) \delta^3 u \\
 B &= \delta u - (a_1 + a) \delta^2 u + (a_2 a_1 + a_2 a + a_1 a) \delta^3 u \\
 A &= u - a \delta u + a_1 a \delta^2 u - a_2 a_1 a \delta^3 u.
 \end{aligned}$$

Putting these values for A, B, C, and D, in u_x , there arises

$$\begin{aligned} u_x &= u + (x-a)\delta u + (x^2 - (a_1+a)x + a_1a)\delta^2 u \\ &\quad + \{x^3 - (a_2+a_1+a)x^2 + (a_2a_1+a_2a+a_1a)x - a_2a_1a\}\delta^3 u \\ &= u + (x-a)\delta u + (x-a_1)(x-a)\delta^2 u + (x-a_2)(x-a_1)(x-a)\delta^3 u. \end{aligned}$$

The form of this result is remarkable, and we may infer from it the general form of u_x , where there are $n+1$ values of x ; as $a, a_1, a_2, a_3, \dots, a_n$, and we shall have

$$\begin{aligned} u_x &= u + (x-a)\delta u + (x-a)(x-a_1)\delta^2 u + (x-a)(x-a_1)(x-a_2)\delta^3 u + \&c. \\ &\quad + (x-a)(x-a_1)(x-a_2)\dots(x-a_n)\delta^n u. \end{aligned}$$

(59.) When the values a_1, a_2, a_3 , &c. are in arithmetic progression, having a common difference h ; then

$$\begin{aligned} \delta u &= \frac{u_1 - u}{a_1 - a} = \frac{\Delta u}{h} & \delta^2 u &= \frac{\delta u_1 - \delta u}{a_2 - a} = \frac{\Delta^2 u}{2h^2} \\ \delta^3 u &= \frac{\delta^2 u_1 - \delta^2 u}{a_3 - a} = \frac{\Delta^3 u}{2 \cdot 3 h^3}, \&c.; \end{aligned}$$

and making

$$\begin{aligned} x-a &= h_1, \therefore x-a_1 = h_1 - h, x-a_2 = h_1 - 2h, \&c.; \\ u_x &= u + \frac{h_1}{h} \Delta u + \frac{h_1(h_1-h)}{1 \cdot 2 \cdot h^2} \Delta^2 u + \frac{h_1(h_1-h)(h_1-2h)}{1 \cdot 2 \cdot 3 h^3} \Delta^3 u + \&c., \end{aligned}$$

which we have previously obtained, and which may be put under the form

$$\Delta' u = \frac{h_1}{h} \Delta u + \frac{h_1(h_1-h)}{1 \cdot 2 \cdot h^2} \Delta^2 u + \frac{h_1(h_1-h)(h_1-2h)}{1 \cdot 2 \cdot 3 h^3} \Delta^3 u + \&c.,$$

by making $\Delta' u = u_x - u$, where $\Delta' u$ expresses the difference for an interval h_1 .

This formula is used by Lacroix to find the logarithm of 3.141592653, having given the logarithm of 3.14, 3.15, 3.16, 3.17, 3.18, and he assumes

$$a = 3.14, x = 3.141592653; \therefore x-a = h_1 = .0015926536 \text{ and } h = .001;$$

and thus obtains the same result as we have done in a preceding article.

(60.) The coefficients $\delta u, \delta u_1, \delta u_2$, &c. have a remarkable form, which we proceed to show, and thence deduce an expression for u_x by a very elegant method due to Lagrange, and which, as we shall see, possesses the greatest advantages.

For since

$$\begin{aligned} \delta u &= \frac{u_1 - u}{a_1 - a} = \frac{u_1}{a_1 - a} + \frac{u}{a - a_1} \\ \delta^2 u &= \frac{\delta u_1 - \delta u}{a_2 - a} = \frac{1}{a_2 - a} \cdot \left\{ \frac{u_2}{a_2 - a_1} + \frac{u_1}{a_1 - a_2} - \frac{u_1}{a_1 - a} - \frac{u}{a - a_1} \right\} \\ &= \frac{1}{a_2 - a} \left\{ \frac{u_2}{a_2 - a_1} + \frac{u_1(a_2 - a)}{(a_1 - a_2)(a_1 - a)} - \frac{u}{a - a_1} \right\} \\ &= \frac{u_2}{(a_2 - a)(a_2 - a_1)} + \frac{u_1}{(a_1 - a_2)(a_1 - a)} + \frac{u}{(a - a_1)(a - a_2)}; \end{aligned}$$

and, similarly,

$$\begin{aligned} \delta^3 u &= \frac{u_3}{(a_3 - a)(a_3 - a_1)(a_3 - a_2)} + \frac{u_2}{(a_2 - a)(a_2 - a_1)(a_2 - a_3)} \\ &\quad + \frac{u_1}{(a_1 - a)(a_1 - a_2)(a_1 - a_3)} + \frac{u}{(a - a_1)(a - a_2)(a - a_3)} \end{aligned}$$

and putting these values in the place of $\delta u, \delta^2 u$, &c., we shall have for u_x

$$\begin{aligned} u_x &= u \left\{ 1 + \frac{x-a}{a-a_1} + \frac{(x-a)(x-a_1)}{(a-a_1)(a-a_2)} + \&c. \right\} + u_1 \left\{ \frac{x-a}{a_1-a} + \frac{x-a}{(a_1-a_2)(a_1-a)} + \&c. \right\} \\ &\quad + \&c. \\ &= Xu + X_1 u_1 + X_2 u_2 + X_3 u_3 + \&c. + X_n u_n, \end{aligned}$$

by substituting X, X_1, X_2 , &c. X_n for the coefficients of u, u_1, u_2 , &c. u_n .

(61.) The equation to which we have been led by the reasoning in the preceding article might have been inferred from the circumstance that the values of A, B, C, &c., of which we have been in search, could not comprise any other than the first powers of the letters u_1, u_2, u_3 , &c., and that these must be in the numerator only.

Let

$$\therefore u_x = Xu + X_1 u_1 + X_2 u_2 + X_3 u_3 + \&c. + X_n u_n,$$

where X, X_1, X_2 , &c. solely depend upon x and a, a_1, a_2 , &c.

Now this equation must fulfil the condition of u_x becoming successively u, u_1, u_2, u_3 , &c. when a, a_1, a_2, a_3 , &c. are put for x ; and these conditions will be fulfilled if we have, when

Calculus of
Finite
Differences.

Calculus of
Finite
Differences.

$$\begin{aligned} x = a, & \quad X = 1, \quad X_1 = 0, \quad X_2 = 0, \quad X_3 = 0, \text{ \&c.}, \quad X_n = 0, \\ x = a_1, & \quad X = 0, \quad X_1 = 1, \quad X_2 = 0, \quad X_3 = 0, \text{ \&c.}, \quad X_n = 0, \\ x = a_2, & \quad X = 0, \quad X_1 = 0, \quad X_2 = 1, \quad X_3 = 0, \text{ \&c.}, \quad X_n = 0, \\ & \vdots \\ x = a_n, & \quad X = 0, \quad X_1 = 0, \quad X_2 = 0, \quad X_3 = 0, \text{ \&c.}, \quad X_n = 1. \end{aligned}$$

If now we read these results in a vertical order, we shall find from the column in which the values of X are tabulated, that $X = 0$, whenever, $x = a_1, a_2, a_3, \text{ \&c.}$, a condition which is satisfied by making

$$x = a \cdot (x - a_1)(x - a_2)(x - a_3) \dots (x - a_n);$$

and that $X = 1$ when $X = a$, a condition which is also satisfied when

$$\alpha = \frac{1}{(a - a_1)(a - a_2)(a - a_3) \dots (a - a_n)};$$

and that all the necessary conditions are fulfilled if

$$X = \frac{(x - a_1)(x - a_2)(x - a_3) \dots (x - a_n)}{(a - a_1)(a - a_2)(a - a_3) \dots (a - a_n)}.$$

In the same manner we may put

$$X_1 = \frac{(x - a)(x - a_2)(x - a_3) \dots (x - a_n)}{(a_1 - a)(a_1 - a_2)(a_1 - a_3) \dots (a_1 - a_n)},$$

$$X_2 = \frac{(x - a)(x - a_1)(x - a_3) \dots (x - a_n)}{(a_2 - a)(a_2 - a_1)(a_2 - a_3) \dots (a_2 - a_n)},$$

$$\vdots$$

$$X_n = \frac{(x - a)(x - a_1)(x - a_2) \dots (x - a_{n-1})}{(a_n - a)(a_n - a_1)(a_n - a_2) \dots (a_n - a_{n-1})}.$$

And thus

$$\begin{aligned} u_x = & \frac{(x - a_1)(x - a_2) \dots (x - a_n)}{(a - a_1)(a - a_2) \dots (a - a_n)} u + \frac{(x - a)(x - a_2) \dots (x - a_n)}{(a_1 - a)(a_1 - a_2) \dots (a_1 - a_n)} u_1 \\ & + \frac{(x - a)(x - a_1) \dots (x - a_n)}{(a_2 - a)(a_2 - a_1) \dots (a_2 - a_n)} \cdot u_2 + \text{\&c.}; \end{aligned}$$

the coefficients of which can be calculated by logarithms.

(62.) The determination of the coefficients $X, X_1, X_2, X_3, \text{ \&c.}$ at once show that the problem of interpolations is an indeterminate one; for any function whatever which would fulfil the requisite conditions might have been assumed as well as that which has been derived from the ordinary theory of equations.

Thus, since $\sin p(x - a_1) \cdot \sin q(x - a_2) \cdot \sin r \cdot (x - a_3) \dots \sin t \cdot (x - a_n)$ vanishes when $x = a_1, a_2, a_3, \text{ \&c.}$, we may assume

$$X = \frac{\sin p(x - a_1) \cdot \sin q \cdot (x - a_2) \dots \sin t(x - a_n)}{\sin p \cdot (a - a_1) \cdot \sin q \cdot (a - a_2) \dots \sin t \cdot (a - a_n)}.$$

And, similarly, for the other terms, and by changing the values of $p, q, r, \text{ \&c.}$, we may have as many values for $X, X_1, \text{ \&c.}$ as we please. Other transformations may also be found; but what is here given is sufficient to show the truth of the proposition, that the problem of interpolations is an indeterminate one.

The Inverse Calculus of Differences.

(63.) In what has preceded our attention has been chiefly directed to the question, To find the difference or successive differences of u_x , when u_x is a given function: we now come to the more important, and, as it so happens to be, the more difficult problem of finding the function from given differences. But, in the first instance, we shall confine ourselves solely to the case in which the difference is an explicit function of the independent variable.

Since $\Delta \cdot (u_x + c)$ and $\Delta \cdot u_x$ give precisely the same results, it will be necessary in reascending from the difference to the function to add to the result a constant quantity, or such a quantity as will not change its value when $x + 1$ is put for x . But it is not necessary that the quantity to be added after integration should be independent of x ; only that its value should not change when $x + 1$ is written for x ; we may, therefore, put c_x to represent the constant, if $c_{x+1} - c_x = 0$, a case which is exemplified by c_x being expressed by $\cos 2\pi x$, for $\cos \cdot 2\pi(x + 1) = \cos(2\pi + 2\pi x) = \cos 2\pi x$; and $\therefore \Delta \cos 2\pi x = 0$.

(64.) The letter Δ prefixed to a function has been used as the sign of the difference of the function; and the letter Σ is also put for the sign of integration, the reverse operation; or Σ and Δ neutralize each other, and

$$\Sigma(\Delta \cdot u_x) = u_x + c.$$

(65.) We have seen in the preceding chapter that

$$\Delta \cdot u_x + \Delta \cdot v_x + \Delta \cdot w_x = \Delta(u_x + v_x + w_x);$$

therefore taking the integral of each side, we have

Calculus of
Finite
Differences.

Calculus of
Finite
Differences.

$$\begin{aligned} & \Sigma \{ \Delta \cdot u_x + \Delta \cdot v_x + \Delta \cdot w_x \} \\ & = u_x + v_x + w_x = \Sigma \cdot (\Delta \cdot u_x) + \Sigma (\Delta \cdot v_x) + \Sigma (\Delta \cdot w_x); \end{aligned}$$

or the integral of the sum of any number of differences is equal to the sum of the integrals of each difference taken separately.

Again, since

$$\begin{aligned} a \cdot \Delta \cdot u_x &= \Delta (a \cdot u_x); \\ \therefore \Sigma (a \cdot \Delta u_x) &= a \cdot u_x = a \Sigma (\Delta \cdot u_x), \end{aligned}$$

it appears that a constant coefficient may be brought without the sign of integration.

(66.) The first case which we shall integrate is that in which u_x is a rational function of x .

It has already been shown that the difference of any rational integral function $Ax^m + Bx^{m-1} + Cx^{m-2} + \&c. + Kx + L$ is itself a rational function of the form

$$A_1 x^{m-1} + B_1 x^{m-2} + C_1 x^{m-3} + \&c. + K_1.$$

Conversely, had we to integrate the latter function, in which the highest index is $m-1$, we may assume its integral to be of the form $Ax^m + Bx^{m-1} + Cx^{m-2} + \&c. + Kx + L$, in which the highest index is m , the difference of which expression must equal the given difference; and having found the difference of the assumed series, the coefficients $A, B, C, \&c. K$ may be determined by equating the coefficients of the same powers of x in the two series.

The last coefficient L will not be found by this process, but remains indeterminate, unless it be known from some given relation.

(67.) An example will illustrate our meaning: let the value of $\Sigma (x^3 + 2x^2 + 1)$ be required.

Assume that

$$\begin{aligned} \Sigma (x^3 + 2x^2 + 1) &= ax^4 + bx^3 + cx^2 + ex + f; \\ \therefore x^3 + 2x^2 + 1 &= \Delta (ax^4 + bx^3 + cx^2 + ex + f) \\ &= a \{ 4x^3 + 6x^2 + 4x + 1 \} + b \cdot (3x^2 + 3x + 1) + c \cdot (2x + 1) + e \\ &= 4ax^3 + (6a + 3b)x^2 + (4a + 3b + 2c)x + a + b + c + e; \\ \therefore 4a &= 1; \therefore a = \frac{1}{4}; \quad 6a + 3b = 2; \therefore b = \frac{1}{3} \left\{ 2 - \frac{3}{2} \right\} = \frac{1}{6}; \\ 4a + 3b + 2c &= 0; \therefore c = \frac{1}{2} \cdot \left\{ -1 - \frac{1}{2} \right\} = -\frac{3}{4}; \\ a + b + c + e &= 0; \therefore e = -\frac{1}{4} - \frac{1}{6} + \frac{3}{4} = \frac{1}{2} - \frac{1}{6} = \frac{1}{3}; \\ \therefore \Sigma (x^3 + 2x^2 + 1) &= \frac{x^4}{4} + \frac{x^3}{6} - \frac{3x^2}{4} + \frac{x}{3} + f. \end{aligned}$$

(68.) In this manner we may find the integral of any rational function. But without attending to particular examples, we will find the integral of x^n .

Let $\Sigma \cdot x^n = Ax^{n+1} + Bx^n + Cx^{n-1} + Dx^{n-2} + Ex^{n-3} + \&c.$

$$\begin{aligned} \therefore x^n &= A \{ (x+1)^{n+1} - x^{n+1} \} + B \{ (x+1)^n - x^n \} + C \{ (x+1)^{n-1} - x^{n-1} \} \\ &\quad + D \{ (x+1)^{n-2} - x^{n-2} \} + E \{ (x+1)^{n-3} - x^{n-3} \} + \&c. \\ &= A \left\{ \overline{n+1} \cdot x^n + \frac{n \overline{n+1}}{2} x^{n-1} + \frac{\overline{n+1} \cdot n \cdot \overline{n-1}}{1 \cdot 2 \cdot 3} x^{n-2} + \frac{\overline{n+1} \cdot n \cdot \overline{n-1} \cdot \overline{n-2}}{1 \cdot 2 \cdot 3 \cdot 4} x^{n-3} + \&c. \right\} \\ &\quad + B \left\{ \overline{n} \cdot x^{n-1} + \frac{n \overline{n-1}}{1 \cdot 2} x^{n-2} + \frac{n \overline{n-1} \cdot \overline{n-2}}{1 \cdot 2 \cdot 3} x^{n-3} + \&c. \right\} \\ &\quad + C \left\{ \overline{n-1} \cdot x^{n-2} + \frac{\overline{n-1} \cdot \overline{n-2}}{1 \cdot 2} x^{n-3} + \&c. \right\} \\ &\quad + D \left\{ \overline{n-2} \cdot x^{n-3} + \&c. \right\} \\ &\quad + \&c. \end{aligned}$$

Equating coefficients:

$$\begin{aligned} A \cdot (n+1) &= 1; \therefore A = \frac{1}{n+1}. \\ A \cdot \frac{n \overline{n+1}}{2} + nB &= 0; \therefore B = -\frac{1}{2} A (n+1) = -\frac{1}{2} \\ \frac{A \cdot n \cdot \overline{n+1} \cdot \overline{n-2}}{1 \cdot 2 \cdot 3} + \frac{B n \overline{n-1}}{1 \cdot 2} + \overline{n-1} \cdot C &= 0; \end{aligned}$$

or

$$\frac{n \overline{n-1}}{2 \cdot 3} - \frac{n \overline{n-1}}{4} + (n-1) C = 0; \therefore C = \frac{1}{2} \cdot \frac{n}{1 \cdot 2 \cdot 3},$$

and

$$\frac{n \overline{n-1} \cdot \overline{n-2}}{2 \cdot 3 \cdot 4} - \frac{n \overline{n-1} \cdot \overline{n-2}}{3 \cdot 4} + \frac{1}{2} \cdot \frac{n \overline{n-1} \cdot \overline{n-2}}{3 \cdot 4} + D = 0; \therefore D = 0.$$

Similarly,

$$E = -\frac{1}{6} \cdot \frac{n \cdot \overline{n-1} \cdot \overline{n-2}}{2 \cdot 3 \cdot 4 \cdot 5}, F = \frac{1}{6} \cdot \frac{\overline{nn-1} \cdot \overline{n-2} \dots \overline{n-4}}{1 \cdot 2 \cdot 3 \dots 7};$$

and we shall have, by pursuing the investigation,

$$\begin{aligned} \Sigma \cdot x^n &= \frac{x^{n+1}}{n+1} - \frac{x^n}{2} + \frac{1}{2} \cdot \frac{n \cdot x^{n-1}}{2 \cdot 3} - \frac{1}{6} \cdot \frac{\overline{nn-1} \cdot \overline{n-2}}{2 \cdot 3 \cdot 4 \cdot 5} \cdot x^{n-3} \\ &+ \frac{1}{6} \cdot \frac{\overline{nn-1} \cdot \overline{n-2} \cdot \overline{n-3} \cdot \overline{n-4}}{2 \cdot 3 \cdot 4 \cdot 5 \cdot 6 \cdot 7} x^{n-5} \\ &- \frac{3}{10} \cdot \frac{\overline{nn-1} \cdot \overline{n-2} \cdot \overline{n-3} \cdot \overline{n-4} \cdot \overline{n-5} \cdot \overline{n-6}}{2 \cdot 3 \cdot 4 \cdot 5 \cdot 6 \cdot 7 \cdot 8 \cdot 9} x^{n-7} \\ &+ \frac{5}{6} \cdot \frac{\overline{nn-1} \cdot \overline{n-2} \cdot \overline{n-3} \cdot \overline{n-4} \dots \overline{n-8}}{2 \cdot 3 \cdot 4 \cdot 5 \cdot 6 \dots 11} x^{n-9} \\ &- \frac{691}{210} \cdot \frac{\overline{nn-1} \cdot \overline{n-2} \cdot \overline{n-3} \dots \overline{n-10}}{2 \cdot 3 \cdot 4 \cdot 5 \dots 13} x^{n-11} \\ &+ \frac{35}{2} \cdot \frac{\overline{nn-1} \cdot \overline{n-2} \cdot \overline{n-3} \dots \overline{n-12}}{2 \cdot 3 \cdot 4 \cdot 5 \dots 15} x^{n-13} \\ &- \frac{3617}{30} \cdot \frac{\overline{nn-1} \cdot \overline{n-2} \cdot \overline{n-3} \dots \overline{n-14}}{2 \cdot 3 \cdot 4 \cdot 5 \dots 17} x^{n-15} \\ &+ \frac{43867}{42} \cdot \frac{n(n-1)(n-2)(n-3) \dots (n-16)}{2 \cdot 3 \cdot 4 \cdot 5 \dots 19} x^{n-17} \\ &- \frac{122277}{110} \cdot \frac{n(n-1)(n-2)(n-3) \dots (n-18)}{2 \cdot 3 \cdot 4 \cdot 5 \dots 21} x^{n-19} \\ &+ \&c. \quad + \text{constant}; \end{aligned}$$

a formula in which that part of the coefficient which depends upon the index n follows an obvious law: but not so the other part. These coefficients give rise to some numbers of singular importance in the theory of series, that we shall not hesitate to point them out in this place, although we shall hereafter more particularly allude to them. If we refer to the coefficients we find a fraction independent of (n) , and another of which the numerator consists of the product of (m) factors, viz., $\overline{nn-1} \cdot \overline{n-2} \dots \overline{n-m+1}$; and the denominator is $= 2 \cdot 3 \cdot 4 \dots m+2$, or the product of $(m+1)$ terms. Now the numbers in question are formed by multiplying the first fraction by $\frac{1}{m+2}$. They are called the *numbers of Bernoulli*, since James Bernoulli first remarked them.

The rule just given will show us that the numbers are, taking no notice of the algebraical signs,

$$\frac{1}{2} \cdot \frac{1}{3}, \frac{1}{6} \cdot \frac{1}{5}, \frac{1}{6} \cdot \frac{1}{7}, \frac{3}{10} \cdot \frac{1}{9}, \&c.,$$

or

$$\frac{1}{6}, \frac{1}{30}, \frac{1}{42}, \frac{1}{30}, \&c.$$

(69.) If we give to n the successive values 0, 1, 2, 3, 4, &c., we shall from the preceding formula find the integrals of 1, x , x^2 , x^3 , &c. Thus

$$\begin{aligned} \Sigma \cdot x^0 &= \Sigma(1) = x + C \\ \Sigma \cdot x &= \frac{x^2}{2} - \frac{x}{2} + C \\ \Sigma \cdot x^2 &= \frac{x^3}{3} - \frac{x^2}{2} + \frac{x}{6} + C \\ \Sigma \cdot x^3 &= \frac{x^4}{4} - \frac{x^3}{2} + \frac{x^2}{4} + C \\ \Sigma \cdot x^4 &= \frac{x^5}{5} - \frac{x^4}{2} + \frac{x^3}{3} - \frac{x}{30} + C \\ \Sigma \cdot x^5 &= \frac{x^6}{6} - \frac{x^5}{3} + \frac{5}{12}x^4 - \frac{x^2}{12} + C \\ \Sigma \cdot x^6 &= \frac{x^7}{7} - \frac{x^6}{2} + \frac{x^5}{2} - \frac{x^3}{6} + \frac{x}{42} + C \\ &+ \&c. \end{aligned}$$

Calculus of
Finite
Differences.

(70.) The utility of such a Table as the preceding is manifest when we have to integrate an algebraical expression consisting of a series of monomials.

Calculus of
Finite
Differences.

Thus, if

$$\begin{aligned} u_x &= x^3 - 3x^2 + 2x + 1 \\ \Sigma u_x &= \Sigma x^3 - 3\Sigma x^2 + 2\Sigma x + \Sigma 1 \\ &= \frac{x^4}{4} - \frac{x^3}{2} + \frac{x^2}{4} - x^3 + \frac{3x^2}{2} - \frac{x}{2} + x^2 - x + x + C \\ &= \frac{x^4}{4} - \frac{3x^3}{2} + \frac{11x^2}{4} - \frac{x}{2}. \end{aligned}$$

(71.) If the $\Sigma(x)$ and $\Sigma(x^2)$ be both considered to commence when $x = 0$, the constant will disappear,

and
$$\Sigma . x^3 = \frac{x^4 - 2x^3 + x^2}{4} = \left(\frac{x^2 - x}{2}\right)^2 = \left(\frac{x^2}{2} - \frac{x}{2}\right)^2 = (\Sigma(x))^2;$$

a remarkable expression, which when translated shows that the sum of the cubes of the natural numbers is equal to the square of the sum of the numbers themselves. Omitting, however, the consideration of particular results, we return to the remark that the integration of the general term x^n gives us a means by which the integration of any algebraical expression may be effected. Still, in some cases, other and more convenient processes may be used by which the integration may be directly performed, and the rule by which it is done is precise and easily to be remembered.

(72.) Thus, whenever it is possible to cause the function to be made equal to the product of a series of factors of the form $a + bx$, $a + b(x + 1)$, &c., we may dispense with the method of the preceding article

For since
$$\begin{aligned} \Delta \{ (a + bx) \cdot (a + b\overline{x+1}) (a + b\overline{x+2}) \dots (a + b\overline{x+n}) \} \\ &= (a + b\overline{x+1}) (a + b\overline{x+2}) \dots (a + b\overline{x+n}) \{ a + b\overline{x+n+1} - a + bx \} \\ &= (a + b\overline{x+1}) (a + b\overline{x+2}) \dots (a + b\overline{x+n}) b\overline{n+1}; \\ \therefore \Sigma \{ (a + b\overline{x+1}) (a + b\overline{x+2}) (a + b\overline{x+3}) \dots (a + b\overline{x+n}) \} &= \frac{(a + bx) (a + b\overline{x+1}) \dots (a + b\overline{x+n})}{b(n+1)}, \end{aligned}$$

or, writing x instead of $(x + 1)$,

$$\Sigma \{ (a + bx) (a + b\overline{x+1}) \dots (a + b\overline{x+n-1}) \} = \frac{(a + b\overline{x-1}) \cdot (a + bx) \dots (a + b\overline{x+n-1})}{b(n+1)};$$

whence we have this rule: To integrate the product of any number of factors which are in arithmetical progression, multiply the function by the term immediately preceding the first of the given factors, and divide this product by the number of terms so increased, and also by the common difference between each term.

Example (1.) Thus to integrate $u_x = (x - 2)(x - 3)(x - 4)$,
since $b = 1$, and $n = 3$;

$$\therefore \Sigma u_x = \frac{(x - 2)(x - 3)(x - 4)(x - 5)}{4} + C.$$

Example (2.) To integrate x^3 by this method, we must first put x^3 into a proper form.

Now

$$\begin{aligned} x^3 &= x \cdot (x^2 - 1) + x = \overline{x-1} \cdot x \cdot \overline{x+1} + x; \\ \therefore \Sigma x^3 &= \frac{\overline{x-2} \cdot \overline{x-1} \cdot x \cdot \overline{x+1}}{4} + \frac{x \cdot \overline{x-1}}{2} + C \\ &= \frac{x \cdot \overline{x-1}}{2} \cdot \left\{ \frac{\overline{x+1} \cdot \overline{x-2}}{2} + 1 \right\} + C = \left(\frac{x \overline{x-1}}{2} \right)^2 + C. \end{aligned}$$

Example (3.) Let

Here

$$u_x = (2x + 1) \cdot (2x + 3) \cdot (2x + 5).$$

$$b = 2 \text{ and } n = 3;$$

$$\therefore \Sigma (2x + 1)(2x + 3)(2x + 5) = \frac{(2x - 1)(2x + 1)(2x + 3) \cdot (2x + 5)}{8} + C.$$

(73.) The only difficulty in the application of this rule is the resolution of the proposed integral function into factorials. The mode of doing this has been shown in a particular case, when $u_x = x^3$, Example (2). A similar method must be applied to other cases, the facility of which depends only upon practice.

The method of indeterminate coefficients may be used as a means of resolving the function into factorials.

Thus, let

$$\begin{aligned} x^3 &= A \cdot \overline{x-1} \cdot x \cdot \overline{x+1} + B \cdot x \cdot \overline{x-1} + C \overline{x-1} + D \\ &= A \cdot (x^3 - x) + B(x^2 - x) + C \cdot x - C + D \\ &= Ax^3 + Bx^2 - (A + B - C)x + D - C; \\ \therefore A &= 1, B = 0, A + C - B = 0; \therefore C = A = 1, D = C = 1; \\ \therefore x^3 &= \overline{x-1} \cdot x \cdot \overline{x+1} + (x - 1) + 1 = \overline{x-1} \cdot x \cdot \overline{x+1} + x. \end{aligned}$$

Again, let

$$2x^2 - 3x + 1 = Ax + Bx + C$$

$$= Ax^2 + (B + A)x + C;$$

$$\therefore A = 2, B + A = -3; \therefore B = -5, C = 1;$$

$$\therefore 2x^2 - 3x + 1 = 2 \cdot x \cdot x + 1 - 5 \cdot x + 1;$$

which is immediately integrable.

(74.) A general expression for x^n consisting of the sums of the products of x and its preceding values, viz., $x-1, x-2, x-3$, &c., may, however, be deduced from the frequently used theorem for u_{x+n} .

For (n) put y , and we have

$$u_{x+y} = u_y + x \cdot \Delta \cdot u_y + \frac{x \cdot x - 1}{2} \Delta^2 \cdot u_y + \frac{x \cdot x - 1 \cdot x - 2}{1 \cdot 2 \cdot 3} \Delta^3 \cdot u_y \\ + \frac{x \cdot x - 1 \cdot x - 2 \cdot x - 3}{1 \cdot 2 \cdot 3 \cdot 4} \Delta^4 \cdot u_y + \&c.$$

Let

$$u_y = y^n; \therefore u_{x+y} = (x+y)^n;$$

$$\therefore (x+y)^n = y^n + x \Delta y^n + \frac{x \cdot x - 1}{1 \cdot 2} \Delta^2 \cdot y^n + \frac{x \cdot x - 1 \cdot x - 2}{1 \cdot 2 \cdot 3} \Delta^3 \cdot y^n + \&c.$$

Make $y = 0$; $\therefore y^n = 0$, and we have

$$x^n = \frac{\Delta \cdot 0^n}{1} x + \frac{\Delta^2 \cdot 0^n}{1 \cdot 2} x \cdot x - 1 + \frac{\Delta^3 \cdot 0^n}{1 \cdot 2 \cdot 3} x \cdot x - 1 \cdot x - 2 + \frac{\Delta^4 \cdot 0^n}{2 \cdot 3 \cdot 4} x \cdot x - 1 \cdot x - 2 \cdot x - 3 + \&c.$$

The values of $\frac{\Delta \cdot 0^n}{1}, \frac{\Delta^2 \cdot 0^n}{1 \cdot 2}, \frac{\Delta^3 \cdot 0^n}{2 \cdot 3}$, &c., may be computed by the Table given in Article (33.)

(75.) But if it be required to resolve x^n into products of the successive factors of x , viz., $(x+1), (x+2)$, &c., write $-x$ for x , and let $u_y = y^{n+1}$;

$$\therefore (y-x)^{n+1} = y^{n+1} - x \cdot \Delta y^{n+1} + \frac{x \cdot x + 1}{1 \cdot 2} \Delta^2 y^{n+1} - \frac{x \cdot x + 1 \cdot x + 2}{2 \cdot 3} \Delta^3 y^{n+1} + \&c.$$

Make $y = 0$, and divide both sides by x :

$$(-1)^{n+1} x^n = - \left\{ \Delta \cdot 0^{n+1} - \frac{\Delta^2 \cdot 0^{n+1}}{2} x + 1 + \frac{\Delta^3 \cdot 0^{n+1}}{2 \cdot 3} x + 1 \cdot x + 2 - \&c. \right\};$$

$$\therefore x^n = (-1)^n \left\{ \Delta \cdot 0^{n+1} - \frac{\Delta^2 \cdot 0^{n+1}}{2} x + 1 + \frac{\Delta^3 \cdot 0^{n+1}}{2 \cdot 3} \cdot x + 1 \cdot x + 2 - \&c. \right\};$$

a general formula when the values of $\Delta \cdot 0^{n+1}, \frac{\Delta^2 \cdot 0^{n+1}}{2}$, &c. are known.

(76.) The following method of resolving x^{n+1} into the sum of the products of coefficients which have a constant difference is too remarkable for its elegance to be omitted here.

Let

$$x^2 = v; \therefore x^{n+1} = x \cdot v^n.$$

Now assume that

$$v^n = A_0 + A_1(v-1) + A_2 \cdot (v-1)(v-4) + A_3 \cdot (v-1)(v-4)(v-9) \\ + \&c. + A_n(v-1)(v-4)(v-9) \dots (v-n^2):$$

an assumption which is possible, since if the factors be multiplied out, the highest power of v is v^n , and there will be $n+1$ equations to determine the $n+1$ constants A_0, A_1, A_2, A_3 , &c. A_n .

To determine these, let v be successively made $= 1, 4, 9$, &c., or $1^2, 2^2, 3^2$, &c.;

$$\therefore 1^{2n} = A_0$$

$$2^{2n} = A_0 + A_1(2^2 - 1^2)$$

$$3^{2n} = A_0 + A_1(3^2 - 1^2) + A_2(3^2 - 1^2)(3^2 - 2^2)$$

$$4^{2n} = A_0 + A_1(4^2 - 1^2) + A_2(4^2 - 1^2) \cdot (4^2 - 2^2) + A_3(4^2 - 1^2)(4^2 - 2^2)(4^2 - 3^2) + \&c.;$$

whence

$$A_0 = 1^{2n}$$

$$A_1 = \frac{2^{2n}}{2^2 - 1^2} + \frac{1^{2n}}{1^2 - 2^2}$$

$$A_2 = \frac{3^{2n}}{(3^2 - 1^2)(3^2 - 2^2)} + \frac{2^{2n}}{(2^2 - 1^2) \cdot (2^2 - 3^2)} + \frac{1^{2n}}{(1^2 - 2^2)(1^2 - 3^2)},$$

&c.

and thus knowing A_0, A_1, A_2 , &c., (the law of which terms is evident),

$$x^{n+1} = x \{ A_0 + A_1(x^2 - 1) + A_2(x^2 - 1)(x^2 - 4) + A_3(x^2 - 1)(x^2 - 4)(x^2 - 9) + \&c. \}$$

$$= A_0 x + A_1 x \cdot x - 1 \cdot x + 1 + A_2 x \cdot x - 2 \cdot x - 1 \cdot x \cdot x + 1 \cdot x + 2$$

$$+ A_3 \cdot x \cdot x - 3 \cdot x - 2 \cdot x - 1 \cdot x \cdot x + 1 \cdot x + 2 \cdot x + 3 + \&c.$$

Calculus of
Finite
Differences.

(77.) Again, if any of the factorials in a given product be wanting, the deficient factors may be restored, and the expression rendered fit for integration, as the following examples will show.

Calculus of
Finite
Differences.

Let $u_x = x(x+1)(x+3)$, and let it be required to complete the factorials.

Then

$$u_x = x \cdot \overline{x+1} \cdot (\overline{x+2} + 1) = x \cdot \overline{x+1} \cdot \overline{x+2} + x \cdot \overline{x+1}.$$

Again, let

$$\begin{aligned} u_x &= x \overline{x+1} \overline{x+2} \overline{x+4} \overline{x+5} \\ &= x \overline{x+1} \overline{x+2} \cdot (\overline{x+3} + 1) (\overline{x+5}) \\ &= x \overline{x+1} \overline{x+2} \overline{x+3} \overline{x+5} + x \cdot \overline{x+1} \overline{x+2} \cdot \overline{x+5} \\ &= x \overline{x+1} \cdot \overline{x+2} \overline{x+3} \overline{x+4} + x \overline{x+1} \overline{x+2} \cdot \overline{x+3} + x \overline{x+1} \overline{x+2} \overline{x+3} + 2x \cdot \overline{x+1} \overline{x+2} \\ &= x \overline{x+1} \overline{x+2} \cdot \overline{x+3} \cdot \overline{x+4} + 2x \overline{x+1} \overline{x+2} \overline{x+3} + 2 \cdot x \overline{x+1} \overline{x+2}. \end{aligned}$$

As another example, let

$$\begin{aligned} u_x &= (2x-1) \cdot (2x+1) (2x+5) \\ &= (2x-1) (2x+1) (2+2x+3) \\ &= 2 \cdot (2x-1) (2x+1) + (2x-1) (2x+1) (2x+3). \end{aligned}$$

These examples will be sufficient to show the manner in which the completion of the factorials is to be performed.

(78.) The next case to be considered is that of rational fractions: of these but few can be integrated.

The integral can, however, always be found when the function u_x is of the form $a + bx$, or

$$\frac{1}{u_x \cdot u_{x+1} \cdot u_{x+2} \dots u_{x+n}} = \frac{1}{(a+bx)(a+b\overline{x+1})(a+b\overline{x+2}) \dots (a+b\overline{x+n})}.$$

$$\begin{aligned} \text{For } \Delta \cdot \frac{1}{(a+bx) \dots (a+b\overline{x+n})} &= \frac{(a+bx) - (a+b\overline{x+n+1})}{(a+bx)(a+b\overline{x+1}) \dots (a+b\overline{x+n+1})} \\ &= \frac{-n+1 \cdot b}{(a+bx)(a+b\overline{x+1}) \dots (a+b\overline{x+n+1})}; \end{aligned}$$

$$\therefore \Sigma \cdot \frac{1}{(a+bx)(a+b\overline{x+1}) \dots (a+b\overline{x+n})} = C - \frac{1}{b \cdot n+1} \cdot \frac{1}{(a+bx) \dots (a+b\overline{x+n})}.$$

Whence this rule: To integrate a fraction, of which the denominator is composed of factors in arithmetic progression, and of which the numerator is constant. Change the algebraical sign of the fraction, efface the last factor, divide the result by the number of terms remaining and by the common difference, and add a constant.

Thus

$$\Sigma \cdot \frac{1}{x \cdot \overline{x+1} \overline{x+2} \overline{x+3}} = C - \frac{1}{3 \cdot x \cdot \overline{x+1} \overline{x+2}},$$

and

$$\Sigma \cdot \frac{1}{(2x-1)(2x+1)(2x+3)} = C - \frac{1}{4(2x-1)(2x+1)}.$$

(79.) If any of the terms of the arithmetic progression be wanting, their place must be supplied by multiplying the numerator and denominator by them, and reducing the fraction to others which have constant numerators.

Thus to integrate $\frac{1}{x+1 \overline{x+2} \overline{x+4}}$,

$$\begin{aligned} \frac{1}{x+1 \overline{x+2} \overline{x+4}} &= \frac{x+3}{x+1 \overline{x+2} \dots \overline{x+4}} = \frac{\overline{x+4} - 1}{x+1 \cdot \overline{x+2} \dots \overline{x+4}} \\ &= \frac{1}{x+1 \overline{x+2} \overline{x+3}} - \frac{1}{x+1 \overline{x+2} \dots \overline{x+4}}; \end{aligned}$$

$$\therefore \Sigma \frac{1}{x+1 \overline{x+2} \overline{x+4}} = C - \frac{1}{2 \cdot x+1 \overline{x+2}} + \frac{1}{3} \cdot \frac{1}{x+1 \overline{x+2} \overline{x+3}}.$$

(80.) And, as a general method, had we to integrate

$$\frac{Ax^n + Bx^{n-1} + Cx^{n-2} + \&c. + M}{(a+bx) \cdot (a+b\overline{x+1}) \dots (a+b\overline{x+n+1})},$$

we may assume that

$$Ax^n + Bx^{n-1} + Cx^{n-2} + \&c. = \alpha + \beta(a+bx) + \gamma(a+bx)(a+b\overline{x+1}) + \&c.;$$

and by multiplying out the terms of the equation on the right hand, there will arise, from equating the similar

Calculus of Finite Differences. powers of x , $(n+1)$ equations, by which the $n+1$ quantities α, β, γ , &c. may be found, and the fraction will be resolved into the following fractions, each of which may be integrated:

Calculus of Finite Differences.

$$\frac{\alpha}{(a+bx)(a+bx+1)\dots(a+bx+n+1)} + \frac{\beta}{(a+b \cdot x+1)\dots(a+bx+n+1)} + \frac{\gamma}{(a+bx+2)\dots(a+bx+n+1)} + \&c.$$

(81.) Next to integrate the function $u_x = a^x$.

Since

$$\Delta \cdot a^x = a^{x+1} - a^x = a^x \cdot (a-1);$$

$$\therefore a^x = \frac{\Delta \cdot a^x}{a-1} \text{ and } \Sigma \cdot a^x = \frac{a^x}{a-1} + C.$$

Also if

$$u_x = a^{bx}; \therefore \Delta u_x = a^{bx} \cdot (a^b - 1); \therefore \Sigma \cdot a^{bx} = \frac{a^{bx}}{a^b - 1} + C.$$

(82.) And since

$$\sin x\theta = \frac{e^{x\theta\sqrt{-1}} - e^{-x\theta\sqrt{-1}}}{\sqrt{-1}} \text{ and } \cos x\theta = \frac{e^{x\theta\sqrt{-1}} + e^{-x\theta\sqrt{-1}}}{2},$$

it is manifest we may integrate $\sin x\theta$ and $\cos x\theta$ by the formula for the integral of a^{bx} . The following method is, however, more simple:

$$\therefore \Delta \cdot \cos x\theta = \cos \overline{x+1}\theta - \cos x\theta = -2 \sin \frac{\theta}{2} \cdot \sin \left(\frac{2x+1}{2} \right) \cdot \theta;$$

$$\therefore \Sigma \cdot \sin \left(\frac{2x+1}{2} \right) \theta = C - \frac{\cos x\theta}{2 \sin \frac{\theta}{2}};$$

or, writing x instead of $\frac{2x+1}{2}$,

$$\therefore \Sigma \cdot \sin x\theta = C - \frac{\cos \left(\frac{2x-1}{2} \right) \cdot \theta}{2 \sin \frac{\theta}{2}}.$$

Again

$$\therefore \Delta \cdot \sin x\theta = \sin \overline{x+1}\theta - \sin x\theta = 2 \sin \frac{\theta}{2} \cdot \cos \frac{2x+1}{2} \theta;$$

$$\therefore \Sigma \cdot \cos \left(\frac{2x+1}{2} \right) \theta = C + \frac{\sin x\theta}{2 \sin \frac{\theta}{2}},$$

or

$$\Sigma \cdot \cos x\theta = C + \frac{\sin \left(\frac{2x+1}{2} \right) \theta}{2 \sin \frac{\theta}{2}}.$$

Also, since $\sin^m x\theta$ and $\cos^m x\theta$ may be expressed in terms of the sines and cosines of the multiples of $x\theta$, their integration may be made to depend upon that of $\sin x\theta$ and $\cos x\theta$; but had we to integrate $a^x \cdot \cos x\theta$ or $a^x \sin x\theta$, it would be better to use the exponential values for the $\sin x\theta$ and $\cos x\theta$, as we will show in the next article.

(83.) Integrate $a^x \cdot \cos x\theta$

$$a^x \cos x\theta = a^x \cdot \left(\frac{e^{x\theta\sqrt{-1}} + e^{-x\theta\sqrt{-1}}}{2} \right) = \frac{1}{2} \{ a^x e^{x\phi} + a^x e^{-x\phi} \}, \text{ where } \phi = \theta \sqrt{-1}.$$

Now

$$\Delta (a^x \cdot e^{x\phi}) = a^{x+1} \cdot e^{\overline{x+1}\phi} - a^x e^{x\phi} = a^x e^{x\phi} \cdot \{ a e^{\phi} - 1 \};$$

$$\therefore a^x e^{x\phi} = \frac{\Delta \cdot (a^x e^{x\phi})}{a e^{\phi} - 1}; \therefore \Sigma (a^x e^{x\phi}) = C + \frac{a^x \cdot e^{x\phi}}{a e^{\phi} - 1};$$

and putting $-\phi$ for ϕ ,

$$\Sigma (a^x e^{-x\phi}) = C + \frac{a^x e^{-x\phi}}{a e^{-\phi} - 1};$$

$$\therefore \Sigma (a^x \cdot \cos x\theta) = C + \frac{1}{e} \cdot \left\{ \frac{a^x \cdot e^{x\phi}}{a e^{\phi} - 1} + \frac{a^x e^{-x\phi}}{a e^{-\phi} - 1} \right\}$$

$$= C + \frac{1}{2} \cdot \left\{ \frac{a^{x+1} \cdot (e^{\overline{x-1} \cdot \phi} + e^{\overline{x-1} \cdot \psi}) - a^x \cdot (e^{\overline{x} \cdot \phi} + e^{\overline{x} \cdot \psi})}{a^2 - a(e^{\overline{x} \cdot \phi} + e^{\overline{x} \cdot \psi}) + 1} \right\}$$

$$= C + \frac{a^{x+1} \cdot \cos x - 1 \theta - a^x \cdot \cos x \theta}{a^2 - 2 a \cos \theta + 1}.$$

In a similar manner may $a^x \sin x \theta$ be integrated.

$$(84.) \text{ Again, since } \Delta(u_x u_{x+1} \dots u_{x+n}) = u_{x+1} u_{x+2} \dots u_{x+n} \cdot (u_{x+n+1} - u_x).$$

$$\text{Let } u_x = p \cdot a^x + q; \therefore u_{x+n+1} - u_x = p \cdot (a^{x+n+1} - a^x) = p \cdot a^x (a^{n+1} - 1);$$

$$\therefore \Delta \{ (p \cdot a^x + q) (p \cdot a^{x+1} + q) \dots (p \cdot a^{x+n} + q) \} = (p \cdot a^{x+1} + q) \dots (p \cdot a^{x+n} + q) p \cdot a^x \cdot (a^{n+1} - 1);$$

$$\therefore \Sigma a^x \cdot (p a^{x+1} + q) \cdot (p a^{x+2} + q) \dots (p a^{x+n} + q) = \frac{(p a^x + q) \cdot (p a^{x+1} + q) \dots (p a^{x+n} + q)}{p (a^{n+1} - 1)} + C.$$

For x put $x-1$; and $\therefore a^{x-1} = \frac{a^x}{a}$.

$$\therefore \Sigma a^x \cdot p a^x + q \cdot p a^{x+1} + q \dots p a^{x+n-1} + q = a \cdot \frac{p a^{x-1} + q \dots p a^{x+n-1} + q}{p (a^{n+1} - 1)} + C.$$

$$(85.) \text{ Again, since } \Delta \cdot \frac{1}{u_x \cdot u_{x+1} \dots u_{x+n-1}} = \frac{-(u_{x+n} - u_x)}{u_x u_{x+1} \dots u_{x+n}}.$$

If $u_x = p a^x + q$;

$$\therefore \Delta \cdot \frac{1}{(p \cdot a^x + q) \dots (p a^{x+n-1} + q)} = \frac{-p a^x \cdot (a^n - 1)}{(p \cdot a^x + q) \dots (p a^{x+n} + q)};$$

and then writing $n-1$ for n , we have

$$\Sigma \frac{a^x}{(p a^x + q) \dots (p a^{x+n-1} + q)} = C - \frac{1}{p (a^{n-1} - 1) (p a^x + q) \dots (p a^{x+n-2} + q)}.$$

The utility of these expressions will be apparent when the results of these integrations are applied to the summation of series.

(86.) Since

$$\Delta(u_x v_x) = u_x \Delta v_x + v_{x+1} \Delta u_x;$$

$$\therefore u_x \Delta v_x = \Delta(u_x v_x) - v_{x+1} \Delta u_x;$$

$$\therefore \Sigma(u_x \cdot \Delta v_x) = u_x v_x - \Sigma(v_{x+1} \Delta u_x),$$

a formula which is analogous to $\int y dx = yx - \int x dy$ used in the Integral Calculus.

Now, writing v_x for $\Delta \cdot v_x$, and $\therefore \Sigma v_x$ for v_x ,

$$\Sigma(u_x v_x) = u_x \Sigma v_x - \Sigma(\Delta u_x \Sigma v_{x+1})$$

$$= u_x \Sigma v_x - \Delta u_x \Sigma^2 v_{x+1} + \Sigma(\Delta^2 u_x \Sigma^2 v_{x+2})$$

$$= u_x \Sigma v_x - \Delta u_x \Sigma^2 v_{x+1} + \Delta^2 u_x \Sigma^3 v_{x+2} - \Delta^3 u_x \Sigma^4 v_{x+3} + \&c.$$

$$\pm \Delta^n u_x \Sigma^{n+1} v_{x+n+1} \mp \Sigma(\Delta^{n+1} u_x \cdot \Sigma^{n+1} v_{x+n+1}),$$

where n may be any integer.

If u_x be a rational function of x , then $\Delta^n u_x$ is constant, and $\Delta^{n+1} u_x = \text{zero}$, and we have

$$\Sigma(u_x v_x) = u_x \Sigma v_x - \Delta u_x \Sigma^2 v_{x+1} + \Delta^2 u_x \Sigma^3 v_{x+2} - \Delta^3 u_x \Sigma^4 v_{x+3} + \&c. \pm \Delta^n \cdot u_x \cdot \Sigma^{n+1} v_{x+n+1}$$

(87.) As an example, let $u_x = x^2$, and $v_x = a^x$.

$$\therefore \Delta u_x = 2x + 1, \Delta^2 u_x = 2, \text{ and } \Delta^3 u_x = 0$$

$$\Sigma v_x = \frac{a^x}{a-1}, \Sigma v_{x+1} = \frac{a^{x+1}}{a-1}, \Sigma^2 v_{x+1} = \frac{a^{x+1}}{(a-1)^2}$$

$$\Sigma^3 v_{x+2} = \frac{a^{x+2}}{(a-1)^3};$$

$$\therefore \Sigma(x^2 \cdot a^x) = \frac{x^2 \cdot a^x}{a-1} - (2x+1) \cdot \frac{a^{x+1}}{(a-1)^2} + 2 \frac{a^{x+2}}{(a-1)^3} + C$$

$$= a^x \left\{ \frac{x^2}{a-1} - \frac{2ax}{(a-1)^2} + \frac{a^2+a}{(a-1)^3} \right\} + C.$$

(88.) Next to obtain general formulæ for $\Sigma^2(u_x v_x)$, $\Sigma^3(u_x v_x)$, &c., and finally $\Sigma^n(u_x v_x)$, we must integrate successively the formula for $\Sigma(u_x v_x)$.

$$\text{And, first, } \Sigma^2(u_x v_x) = \Sigma(u_x \Sigma v_x) - \Sigma(\Delta u_x \cdot \Sigma^2 v_{x+1}) + \&c. \pm \Sigma(\Delta^n u_x \Sigma^{n+1} v_{x+n+1})$$

$$\mp \Sigma^2(\Delta^{n+1} u_x \cdot \Sigma^{n+1} v_{x+n+1}).$$

In this formula we must separately find the terms on the right-hand side of the equation by means of the formula for $\Sigma(u_x v_x)$.

First, for $\Sigma(u_x \Sigma v_x)$; writing Σv_x instead of v_x , we get

$$\Sigma(u_x \Sigma v_x) = u_x \Sigma^2 v_x - \Delta u_x \cdot \Sigma^3 v_{x+1} + \Delta^2 u_x \Sigma^4 v_{x+2} - \&c.$$

$$\pm \Delta^n u_x \Sigma^{n+2} v_{x+n} \mp \Sigma(\Delta^{n+1} u_x \cdot \Sigma^{n+2} v_{x+n+1}).$$

Again, for $\Sigma(\Delta u_x \cdot \Sigma^2 v_{x+1})$; writing Δu_x for u_x , $\Sigma^2 v_{x+1}$ for v_x , and $n-1$ for n ,
 $\Sigma(\Delta u_x \cdot \Sigma^2 v_{x+1}) = \Delta u_x \Sigma^3 v_{x+1} - \&c. \mp \Delta^n u_x \Sigma^{n+2} v_{x+n}$
 $\pm \Sigma(\Delta^{n+1} u_x \cdot \Sigma^{n+2} v_{x+n+1});$

and thus

$$\Sigma(\Delta^n u_x \cdot \Sigma^{n+1} v_{x+n}) = \Delta^n u_x \Sigma^{n+2} v_{x+n} - \Sigma(\Delta^{n+1} u_x \cdot \Sigma^{n+2} v_{x+n+1}).$$

Substituting these values in the expression we have

$$\Sigma^2(u_x v_x) = u_x \cdot \Sigma^2 v_x - 2 \Delta u_x \Sigma^3 v_{x+1} + 3 \Delta^2 u_x \Sigma^4 v_{x+2} - 4 \Delta^3 u_x \Sigma^5 v_{x+3} + \&c.$$

$$\pm (n+1) \Delta^n u_x \cdot \Sigma^{n+2} v_{x+n}$$

$$\mp n+1 \Sigma(\Delta^{n+1} u_x \cdot \Sigma^{n+2} v_{x+n+1}) \mp \Sigma^2(\Delta^{n+1} u_x \Sigma^{n+1} v_{x+n+1}).$$

(89.) If this equation be again integrated by a method similar to that just adopted, we shall get

$$\Sigma^3(u_x v_x) = u_x \Sigma^3 v_x - 3 \Delta u_x \Sigma^4 v_{x+1} + 6 \Delta^2 u_x \Sigma^5 v_{x+2} - \&c.$$

$$\pm \frac{n+1}{1 \cdot 2} \Delta^n u_x \Sigma^{n+3} v_{x+n}$$

$$\mp \frac{n+1}{1 \cdot 2} \Sigma(\Delta^{n+1} u_x \cdot \Sigma^{n+3} v_{x+n+1})$$

$$\mp \frac{n+1}{1} \Sigma^2(\Delta^{n+1} u_x \cdot \Sigma^{n+2} v_{x+n+1}) \mp \Sigma^3(\Delta^{n+1} u_x \cdot \Sigma^{n+1} v_{x+n+1}).$$

And finally, we have

$$\Sigma^m(u_x v_x) = u_x \Sigma^m v_x - m \Delta u_x \Sigma^{m+1} v_{x+1} + \frac{m(m+1)}{1 \cdot 2} \Delta^2 u_x \Sigma^{m+2} v_{x+2} - \&c.$$

$$\pm \frac{n+1}{1 \cdot 2 \dots (m-1)} \Delta^n u_x \Sigma^{n+m} v_{x+n}$$

$$\mp \left\{ \begin{array}{l} \Sigma^m(\Delta^{n+1} u_x \cdot \Sigma^{n+1} v_{x+n+1}) + n+1 \cdot \Sigma^{m-1}(\Delta^{n+1} u_x \cdot \Sigma^{n+2} v_{x+n+1}) \\ + \&c. + \frac{(n+1)(n+2) \dots (n+m-1)}{1 \cdot 2 \dots (m-1)} \cdot \Sigma(\Delta^{n+1} u_x \cdot \Sigma^{n+m} v_{x+n+1}) \end{array} \right\}.$$

It will be observed that the law of the coefficients of this series (first given by Taylor) follows that of the coefficients of the binomial $(1+x)^{-n}$.

For

$$(1+x)^{-n} = 1 - nx + \frac{n(n+1)}{2} x^2 - \frac{n(n+1)(n+2)}{1 \cdot 2 \cdot 3} x^3 + \&c.$$

$$\pm \frac{n(n+1)(n+2) \dots (n+m-1)}{1 \cdot 2 \cdot 3 \dots m} x^m \mp \&c.$$

(90.) Returning to the theorem for $\Sigma(u_x v_x)$, and putting instead of $v_{x+1}, v_{x+2} \dots v_{x+n}$ their values in terms of v_x , we get

$$\Sigma(u_x v_x) = u_x \Sigma v_x - \Delta u_x (\Sigma^2 v_x + \Sigma v_x) + \Delta^2 u_x (\Sigma^3 v_x + 2 \Sigma^2 v_x + \Sigma v_x)$$

$$- \Delta^3 u_x (\Sigma^4 v_x + 3 \Sigma^3 v_x + 3 \Sigma^2 v_x + \Sigma v_x) + \&c.;$$

the form under which the theorem was given by Condorcet in his application of analysis to questions of Probabilities.

(91.) We may now classify those functions which it will be possible to integrate.

In the first place, if u_x be a rational function of x , such that $u_x = Ax^m + Bx^{m-1} + Cx^{m-2} + \&c. + L$, then $\Delta^m u_x = m(m-1)(m-2) \dots 2 \cdot 1 \cdot A$, and $\Delta^{m+1} u_x = 0$; and therefore the formula for $\Sigma(u_x v_x)$ will terminate after a given number of terms. And we have seen that if v_x be a fraction whose denominator is a set of factorials in arithmetic progression and numerator constant, that its integral is at once to be found.

Again, if v_x be either an exponential function of x , or a function of the sines and cosines, Σv_x may be found.

Hence we may integrate

1. Every function of the form

$$\frac{Ax^\alpha + Bx^\beta + Cx^\gamma + \&c. + L}{(a+bx)(a+bx+1) \dots (a+bx+n-1)},$$

when the index of x is less than $n-1$; for the fraction

$$\frac{1}{(a+bx) \cdot (a+bx+1) \dots (a+bx+n-1)}$$

can only be integrated $n-1$ times, since the number of the factors of the denominator diminish by unity at each integration, and we cannot integrate when there is but one factor remaining.

Calculus of
Finite
Differences.

And 2. Every function of the form

$$a^{mx} \cdot (A x^\alpha + B x^\beta + C x^\gamma + \&c.)$$

may be integrated, whatever be the value of m ; α , β , &c. being integers.

And 3. Every function of the form

$$(\sin x)^m \cdot (\cos x)^n \{A x^\alpha + B x^\beta + C x^\gamma + \&c.\},$$

m and n being positive, and $\overline{\cos x}^n \cdot \overline{\sin x}^m$ being changed into expressions involving the sines and cosines of the multiple arcs.

(92.) These three cases include almost all the compound functions to which the inverse method of differences can be at once applied, and they merit particular attention both on that account and also since they lead to the summation of a great number of series.

The application of the formula for reduction may be shown in the annexed example.

Integrate $x^2 \cdot \cos x \theta$.

Here

$$u_x = x^2, \Delta u_x = 2x + 1, \Delta^2 u_x = 2, \Delta^3 u_x = 0,$$

$$v_x = \cos x \theta, v_{x+1} = \cos x + 1 \theta, v_{x+2} = \cos x + 2 \theta;$$

$$\therefore \Sigma (x^2 \cos x \theta) = x^2 \cdot \Sigma (\cos x \theta) - (2x + 1) \Sigma^2 \cdot \cos x + 1 \theta + 2 \Sigma^3 \cdot \cos x + 2 \theta;$$

and as $\Sigma \cdot \cos x \theta$ and $\Sigma \cdot \sin x \theta$ have already been found, we can deduce from the results thus known the values of $\Sigma^2 \cos x + 1 \theta$ and $\Sigma^3 \cdot \cos x + 2 \theta$, and thus $\Sigma (x^2 \cos x \theta)$ will be determined; or we may integrate it by

putting for $\cos x \theta$ its value $\frac{e^{x\theta\sqrt{-1}} + e^{-x\theta\sqrt{-1}}}{2}$, or writing ϕ for $\theta \sqrt{-1}$, by putting $\cos x \theta = \frac{1}{2} (e^{x\phi} + e^{-x\phi})$;

$$\therefore \Sigma (x^2 \cos x \theta) = \frac{1}{2} \{ \Sigma \cdot x^2 e^{x\phi} + \Sigma \cdot x^2 \cdot e^{-x\phi} \}$$

$$= \frac{1}{2} \{ x^2 \Sigma (e^{x\phi} + e^{-x\phi}) - (2x + 1) \Sigma^2 \cdot (e^{x\phi} + e^{-x\phi}) + 2 \Sigma^3 (e^{x\phi} + e^{-x\phi}) \},$$

which may be found without difficulty.

(93.) The integration of the general function u_x is of the greatest importance in the summation of series, and necessarily attracted the attention of mathematicians. Euler has shown how it may be made to depend upon the differential coefficients of u_x , and on the integral $\int u_x dx$. We may arrive at the result by the following process.

Since $u_{x+1} = f(x+1)$, where $u_x = f(x)$, we have, by Taylor's theorem,

$$\Delta \cdot u_x = \frac{d \cdot u_x}{dx} + \frac{d^2 u_x}{dx^2} \frac{1}{1 \cdot 2} + \frac{d^3 u_x}{dx^3} \frac{1}{2 \cdot 3} + \frac{d^4 u_x}{dx^4} \frac{1}{2 \cdot 3 \cdot 4} + \&c.;$$

or, writing $\Sigma (u_x)$ for u_x , and consequently u_x for $\Delta \cdot u_x$,

$$u_x = \frac{d \cdot \Sigma u_x}{dx} + \frac{d^2 \Sigma u_x}{dx^2} \frac{1}{1 \cdot 2} + \frac{d^3 \cdot \Sigma u_x}{dx^3} \frac{1}{2 \cdot 3} + \&c.$$

Now assume that

$$\Sigma \cdot (u_x) = A \int u_x dx + B u_x + C \cdot \frac{d u_x}{dx} + D \cdot \frac{d^2 u_x}{dx^2} + E \cdot \frac{d^3 u_x}{dx^3} + \&c.,$$

where A , B , C , &c. are to be determined. A little reflection will show the justness of this assumption.

$$\therefore \frac{d \cdot \Sigma \cdot u_x}{dx} = A u_x + B \cdot \frac{d u_x}{dx} + C \cdot \frac{d^2 u_x}{dx^2} + D \cdot \frac{d^3 u_x}{dx^3} + \&c.$$

$$\frac{d^2 \Sigma u_x}{dx^2} = A \cdot \frac{d u_x}{dx} + B \cdot \frac{d^2 u_x}{dx^2} + C \cdot \frac{d^3 u_x}{dx^3} + \&c.$$

$$\frac{d^3 \Sigma u_x}{dx^3} = A \cdot \frac{d^2 u_x}{dx^2} + B \cdot \frac{d^3 u_x}{dx^3} + \&c.$$

$$\frac{d^4 \cdot \Sigma u_x}{dx^4} = A \cdot \frac{d^3 u_x}{dx^3} + \&c.$$

$$\&c. = + \&c. + \&c.$$

$\therefore$, substituting

$$u_x = A u_x + B \frac{d u_x}{dx} + C \cdot \frac{d^2 u_x}{dx^2} + D \frac{d^3 u_x}{dx^3} + E \cdot \frac{d^4 u_x}{dx^4} + \&c.$$

$$+ \frac{A}{1 \cdot 2} \cdot \frac{d \cdot u_x}{dx} + \frac{B}{1 \cdot 2} \cdot \frac{d^2 u_x}{dx^2} + \frac{C}{1 \cdot 2} \cdot \frac{d^3 u_x}{dx^3} + \frac{D}{1 \cdot 2} \frac{d^4 u_x}{dx^4} + \&c.$$

$$+ \frac{A}{2 \cdot 3} \cdot \frac{d^2 u_x}{dx^2} + \frac{B}{2 \cdot 3} \cdot \frac{d^3 u_x}{dx^3} + \frac{C}{2 \cdot 3} \cdot \frac{d^4 u_x}{dx^4} + \&c.$$

$$+ \frac{A}{2 \cdot 3 \cdot 4} \cdot \frac{d^3 u_x}{dx^3} + \frac{B}{2 \cdot 3 \cdot 4} \frac{d^4 u_x}{dx^4} + \&c.$$

$$+ \frac{A}{2 \cdot 3 \cdot 4 \cdot 5} \frac{d^4 u_x}{dx^4} + \&c.$$

Equating the coefficients of u_x , and putting the coefficients of the other terms equal to zero, we obtain

$$A = 1$$

$$B + \frac{A}{2} = 0$$

$$\therefore B = -\frac{1}{2}.$$

$$C + \frac{B}{2} + \frac{A}{2 \cdot 3} = 0$$

$$\therefore C = \frac{1}{4} - \frac{1}{2 \cdot 3} = \frac{1}{2} \cdot \frac{1}{2 \cdot 3}$$

$$D + \frac{C}{2} + \frac{B}{2 \cdot 3} + \frac{A}{2 \cdot 3 \cdot 4} = 0$$

$$\therefore D = -\frac{1}{2 \cdot 3 \cdot 4} + \frac{1}{3 \cdot 4} - \frac{1}{2 \cdot 3 \cdot 4} = 0$$

$$E + \frac{C}{2 \cdot 3} + \frac{B}{2 \cdot 3 \cdot 4} + \frac{A}{2 \cdot 3 \cdot 4 \cdot 5} = 0$$

$$\therefore E = \frac{1}{2 \cdot 3} \cdot \left\{ -\frac{1}{3 \cdot 4} + \frac{1}{2 \cdot 4} - \frac{1}{4 \cdot 5} \right\} = -\frac{1}{2 \cdot 3} \cdot \frac{1}{2 \cdot 3 \cdot 4 \cdot 5}$$

&c.

= &c.;

$$\therefore \Sigma u_x = \int u_x dx - \frac{1}{2} u_x + \frac{1}{2} \cdot \frac{1}{2 \cdot 3} \cdot \frac{d \cdot u_x}{dx} - \frac{1}{6} \cdot \frac{1}{2 \cdot 3 \cdot 4 \cdot 5} \cdot \frac{d^3 u_x}{dx^3} + \&c.$$

We can immediately from this series arrive at the expression for Σx^m , which has been made the subject of a former article.

For if

$$u_x = x^m; \therefore \frac{d u_x}{dx} = m x^{m-1}, \frac{d^3 u_x}{dx^3} = m \cdot \overline{m-1} \cdot \overline{m-2} \cdot x^{m-3} + \&c.;$$

$$\therefore \Sigma x^m = \frac{x^{m+1}}{m+1} - \frac{1}{2} \cdot x^m + \frac{1}{2} \cdot \frac{m \cdot x^{m-1}}{2 \cdot 3} - \frac{1}{6} \cdot \frac{m \cdot \overline{m-1} \cdot \overline{m-2}}{2 \cdot 3 \cdot 4 \cdot 5} x^{m-3} + \&c.$$

But we hasten, from particular examples of this formula, to explain an extension of our symbolical notation.

(94.) The formula of Lagrange, $\Delta^n u_x = (e^{\frac{d}{dx}} - 1)^n u_x$, which has been proved to be true for positive values of n , may be shown true when n is negative, and thence we may infer the truth of the equation $\Sigma^n u_x = (e^{\frac{d}{dx}} - 1)^{-n} u_x$.

For if we have any expression of differences, as

$$A \Delta^m u_x + B \Delta^n u_x + C \Delta^p u_x + \&c.,$$

and it be integrated, or the symbol Σ be placed before it, the result will be $A \Delta^{m-1} u_x + B \Delta^{n-1} u_x + C \Delta^{p-1} u_x + \&c.$, i. e. the symbols Σ and Δ^{-1} are identical.

Again, if we integrate the expression a second time, or place before the original expression the symbol Σ^2 , the result will be of the form $A \cdot \Delta^{m-2} u_x + B \cdot \Delta^{n-2} u_x + C \cdot \Delta^{p-2} u_x + \&c.$, and thus it appears that Σ^2 and Δ^{-2} are equivalent; and thus Σ^n and Δ^{-n} are equivalent; or, since $\Delta^n = \frac{1}{\Delta^{-n}} = \frac{1}{\Sigma^n}$, it is evident, and Σ^n and Δ^n are inverse expressions, and when applied to the same quantity neutralize each other, and hence $\Sigma^n \Delta^n \cdot u_x = u_x$, the constants which arise from the integrations being omitted.

Hence, also, it appears that whenever in any expansion of the functions $f\left(\frac{d}{dx}\right)$ or $f(\Delta)$ we meet with terms of the form $\left(\frac{d}{dx}\right)^{-n}$ or Δ^{-n} , we may change these symbols into $\int^n$ and Σ^n .

Now assuming the truth of the equation

$$\Delta^n u_x = (e^{\frac{d}{dx}} - 1)^n u_x.$$

Let it be integrated (n) times;

$$\therefore \Sigma^n \cdot \Delta^n \cdot u_x = \Sigma^n \cdot (e^{\frac{d}{dx}} - 1)^n u_x.$$

But

$$\Sigma^n \cdot \Delta^n u_x = u_x; \therefore u_x = \Sigma^n \cdot (e^{\frac{d}{dx}} - 1)^n \cdot u_x.$$

Hence $\Sigma^n \cdot (e^{\frac{d}{dx}} - 1)^n$ should be equal to unity, or Σ^n should make the index of $(e^{\frac{d}{dx}} - 1)$ equal to zero; but this will be the case if $\Sigma^n = (e^{\frac{d}{dx}} - 1)^{-n}$, and hence $\Sigma^n \cdot u_x = (e^{\frac{d}{dx}} - 1)^{-n} \cdot u_x$.

This would be also apparent, if we are at once allowed to separate the symbols Σ^n and $(e^{\frac{d}{dx}} - 1)^n$, treating them as different quantities, for then

$$\Sigma^n = \frac{1}{(e^{\frac{d}{dx}} - 1)^n} = (e^{\frac{d}{dx}} - 1)^{-n}; \text{ and } \therefore \Sigma^n u_x = (e^{\frac{d}{dx}} - 1)^{-n} u_x.$$

(95.) If we make $n = 1$, then $\Sigma(u_x) = \frac{u_x}{e^{\frac{d}{dx}} - 1} = u_x \frac{1}{e^t - 1}$, where t is put for $\frac{d}{dx}$;

$$\therefore \Sigma u_x = u_x \left(\frac{1}{t + \frac{t^2}{1 \cdot 2} + \frac{t^3}{2 \cdot 3} + \frac{t^4}{2 \cdot 3 \cdot 4} + \&c.} \right)$$

And assuming
we find

$$\frac{1}{e^t - 1} = \frac{A}{t} + B + C t + D t^2 + E t^3 + F t^4 + \&c.,$$

$$A = 1, B = -\frac{1}{2}, C = +\frac{1}{2} \cdot \frac{1}{2 \cdot 3}, D = 0, E = -\frac{1}{6} \cdot \frac{1}{2 \cdot 3 \cdot 4 \cdot 5} \&c.;$$

$$\therefore \Sigma(u_x) = \frac{u_x}{t} - \frac{1}{2} u_x + \frac{1}{2} \cdot \frac{t \cdot u_x}{2 \cdot 3} - \frac{1}{6} \cdot \frac{t^3 \cdot u_x}{2 \cdot 3 \cdot 4 \cdot 5} + \&c.;$$

or restoring the values of t , and recalling to mind the signification of t^{-1} ,

$$\Sigma(u_x) = \int u_x dx - \frac{1}{2} u_x - \frac{1}{2} \cdot \frac{1}{2 \cdot 3} \cdot \frac{d \cdot u_x}{dx} - \frac{1}{6} \cdot \frac{1}{2 \cdot 3 \cdot 4 \cdot 5} \cdot \frac{d^3 u_x}{dx^3} + \&c.,$$

the formula we have already found by a direct process.

(96.) We may write the sum of u_x in another form by introducing the representatives of the numbers of Bernoulli, the law of which we shall presently determine: thus

$$\Sigma(u_x) = \int u_x dx - \frac{1}{2} u_x + B_1 \cdot \frac{1}{1 \cdot 2} \frac{d \cdot u_x}{dx} - B_3 \cdot \frac{1}{2 \cdot 3 \cdot 4} \frac{d^3 u_x}{dx^3} + \&c.$$

(97.) We now proceed to find the law of these numbers. We have just seen that if $\frac{1}{e^t - 1}$ or $\frac{t}{e^t - 1}$ be expanded according to the powers of t , that the numerical coefficients taken in order are the same as those of the expansion of Σu_x , or are the same as those of $\int u_x dx, u_x, \frac{d u_x}{dx}, \&c.$; and

$$\therefore \frac{1}{e^t - 1} = \frac{A}{t} + B + C t + E t^3 + \&c.,$$

and

$$\therefore \frac{t}{e^t - 1} = A + B t + C t^2 + E t^4 + \&c.$$

we might infer that there would be no odd powers of t except the first in the expansion for $\frac{t}{e^t - 1}$; but it may be thus shown:

Let

$$f(t) = \frac{t}{e^t - 1};$$

$$\therefore f(-t) = \frac{-t}{e^{-t} - 1} = \frac{t \cdot e^t}{e^t - 1};$$

$$\therefore f(t) - f(-t) = -t \frac{e^t - 1}{e^t - 1} = -t.$$

Now assume

$$f(t) = a_0 + a_1 t + a_2 t^2 + a_3 t^3 + a_4 t^4 + a_5 t^5 + \&c.;$$

$$\therefore f(-t) = a_0 - a_1 t + a_2 t^2 - a_3 t^3 + a_4 t^4 - a_5 t^5 + \&c.;$$

$$\therefore f(t) - f(-t) = t = 2 a_1 t + 2 a_3 t^3 + 2 a_5 t^5 + \&c.;$$

$$\therefore 2 a_1 = 1; \therefore a_1 = \frac{1}{2}, a_3 = 0, a_5 = 0, \&c.;$$

and hence we can only express $\frac{t}{e^t - 1}$ in a series of the form

$$\frac{t}{e^t - 1} = 1 - \frac{t}{2} + B_1 \frac{t^2}{1 \cdot 2} - B_3 \frac{t^4}{2 \cdot 3 \cdot 4} + B_5 \frac{t^6}{2 \cdot 3 \cdot 4 \cdot 5 \cdot 6} - \&c.,$$

 $B_1, B_3, B_5, \&c.$ being the numbers of Bernoulli, whose law we proceed to find.(98.) If we attempt to find $B_1, B_3, B_5, \&c.$ by means of Maclaurin's theorem, the differential coefficients of $\frac{t}{e^t - 1}$ become $\frac{0}{0}$ when $t = 0$; and that theorem is therefore inapplicable for the purpose. Laplace avoided the difficulty by an ingenious artifice, which we proceed to give.

Since

$$\frac{a}{x^2 - 1} = \frac{\frac{a}{2}}{x - 1} - \frac{\frac{a}{2}}{x + 1},$$

where x may be $e^{\frac{t}{2}}$;

$$\therefore f(t) = \frac{t}{e^t - 1} = \frac{\frac{t}{2}}{e^{\frac{t}{2}} - 1} - \frac{\frac{t}{2}}{e^{\frac{t}{2}} + 1} = f\left(\frac{t}{2}\right) - \frac{\frac{t}{2}}{e^{\frac{t}{2}} + 1};$$

$$\therefore f\left(\frac{t}{2}\right) - f(t) = \frac{\frac{t}{2}}{e^{\frac{t}{2}} + 1}.$$

And hence the coefficient of t^{2x} in $f\left(\frac{t}{2}\right) - f(t)$ and in $\frac{\frac{t}{2}}{e^{\frac{t}{2}} + 1}$ will be the same.

Now let a_{2x} be the coefficient of t^{2x} in the expansion of $\frac{t}{e^t + 1}$; $\therefore \frac{a_{2x}}{2^{2x}}$ will be the coefficient of t^{2x} in the expansion of $\frac{\frac{t}{2}}{e^{\frac{t}{2}} + 1}$. Also let b_{2x} be the coefficient of t^{2x} in the expansion of $f(t)$, therefore $\frac{b_{2x}}{2^{2x}}$ will be the coefficient of t^{2x} in the expansion of $f\left(\frac{t}{2}\right)$, and we shall have for the coefficient of t^{2x} in $f\left(\frac{t}{2}\right) - f(t)$ the expression $b_{2x} \cdot \left(\frac{1}{2^{2x}} - 1\right)$;

$$\therefore b_{2x} \left\{ \frac{1}{2^{2x}} - 1 \right\} = \frac{a_{2x}}{2^{2x}};$$

$$\therefore b_{2x} = -\frac{a_{2x}}{2^{2x} - 1}.$$

But from the series for $\frac{t}{e^t - 1}$ we have the coefficient of t^{2x} , or

$$(-1)^{x+1} \cdot B_{2x-1} \cdot \frac{1}{1 \cdot 2 \cdot 3 \dots 2x} = b_{2x} = -\frac{a_{2x}}{2^{2x} - 1};$$

$$\therefore B_{2x-1} = (-1)^x \cdot \frac{1 \cdot 2 \cdot 3 \cdot 4 \dots 2x}{2^{2x} - 1} \cdot a_{2x}(1).$$

(99.) We have now to determine the value of a_{2x} , and here the ordinary method will apply, since the differential coefficients of $\frac{t}{e^t + 1}$ do not become vanishing fractions when $t = 0$.

Let $u =$ the function $\frac{1}{e^t + 1}$, then since a_{2x} is the coefficient of t^{2x} in the expansion of $\frac{t}{e^t + 1}$ it must be the coefficient of t^{2x-1} in the expansion of $\frac{1}{e^t + 1}$, or of u ;

$$\therefore a_{2x} = \frac{1}{1 \cdot 2 \cdot 3 \dots (2x-1)} \cdot \frac{d^{2x-1} u}{dt^{2x-1}} (2), \text{ when } t = 0.$$

A few differentiations will show us that $\frac{d^{2x-1} u}{dt^{2x-1}}$ must always be of the form

$$\frac{d^{2x-1} u}{dt^{2x-1}} = \frac{a + b e^t + c e^{2t} + f \cdot e^{3t} + \&c. + k e^{2x-1} t}{(1 + e^t)^{2x}};$$

and, multiplying both sides by $(1 + e^t)^{2x}$, we obtain

$$(1 + e^t)^{2x} \cdot \frac{d^{2x-1} u}{dt^{2x-1}} = a + b e^t + c \cdot e^{2t} + f e^{3t} + \&c. + k \cdot e^{2x-1} t;$$

from which it appears that, however developed, the left-hand side can contain only positive powers of t .

Now make

$$e^t = v; \therefore \frac{1}{e^t + 1} = \frac{1}{v + 1} = (v + 1)^{-1};$$

$$\therefore u = (v + 1)^{-1} = v^{-1} - v^{-2} + v^{-3} - v^{-4} + v^{-5} - v^{-6} + \&c.$$

$$\therefore \frac{du}{dt} = \frac{du}{dv} \frac{dv}{dt} = \frac{du}{dv} v = -v^{-1} + 2v^{-2} - 3v^{-3} + 4v^{-4} - 5v^{-5} + 6v^{-6} - \&c.$$

$$\frac{d^2 u}{dt^2} = 1^2 \cdot v^{-1} - 2^2 v^{-2} + 3^2 v^{-3} - 4^2 v^{-4} + 5^2 v^{-5} - \&c.$$

$$\&c. = \&c.;$$

$$\therefore \frac{d^{2x-1} u}{dt^{2x-1}} = -(1^{2x-1} v^{-1} - 2^{2x-1} v^{-2} + 3^{2x-1} v^{-3} - 4^{2x-1} v^{-4} + \&c.);$$

and

Calculus of
Finite
Differences.Calculus of
Finite
Differences

$$(1 + e^t)^{2x} = (v + 1)^{2x} = v^{2x} + 2x \cdot v^{2x-1} + \frac{2x \cdot 2x-1}{1 \cdot 2} v^{2x-2} + \frac{2x \cdot 2x-1 \cdot 2x-2}{1 \cdot 2 \cdot 3} v^{2x-3} + \&c.$$

Multiplying these equations together, and omitting all the negative powers of v , since they must necessarily destroy each other, we have for $a + b e^t + c e^{2t} + \&c. + k e^{2x-1t}$ the expression

$$\begin{aligned} & -1^{2x-1} \cdot 2^{2x-1} + (2^{2x-1} - 2x \cdot 1^{2x-1}) v^{2x-2} \\ & - (3^{2x-1} - 2x \cdot 2^{2x-1} + 2x \cdot \left(\frac{2x-1}{2}\right) 1^{2x-1}) v^{2x-3} + \&c. \\ & + \&c. \\ & = (1 + e^t)^{2x} \cdot \frac{d^{2x-1} u}{d t^{2x-1}}. \end{aligned}$$

Now make $t = 0$, or $e^t = v = 1$, and putting U_{2x-1} instead of the differential coefficient,

$$\begin{aligned} \therefore 2^{2x} \cdot U_{2x-1} &= -1^{2x-1} + (2^{2x-1} - 2x \cdot 1^{2x-1}) \\ & - \left(3^{2x-1} - 2x \cdot 2^{2x-1} + 2x \cdot \frac{2x-1}{2} 1^{2x-1}\right) \\ & + \&c. \qquad \qquad \qquad + \&c. \end{aligned}$$

$$\therefore a_{2x} = \frac{U_{2x-1}}{1 \cdot 2 \cdot 3 \dots (2x-1)} \cdot \frac{1}{2^{2x}};$$

and, therefore, we have for the x th number of Bernoulli

$$\begin{aligned} B_{2x-1} &= (-1)^x \frac{1 \cdot 2 \cdot 3 \dots 2x}{2^{2x} - 1} \cdot \frac{U_{2x-1}}{1 \cdot 2 \cdot 3 \dots 2x-1} \cdot \frac{1}{2^{2x}} \\ &= \frac{(-1)^{x+1} \cdot 2x}{2^{2x} \cdot (2^{2x} - 1)} \left[\begin{aligned} & 1^{2x-1} - (2^{2x-1} - 2x \cdot 1^{2x-1}) \\ & + \left(3^{2x-1} - 2x \cdot 2^{2x-1} + 2x \cdot \frac{2x-1}{2} \cdot 1^{2x-1}\right) \\ & - \left(4^{2x-1} - 2x \cdot 3^{2x-1} + \frac{2x \cdot 2x-1}{1 \cdot 2} \cdot 2^{2x-1} - \frac{2x \cdot 2x-1 \cdot 2x-2}{1 \cdot 2 \cdot 3} 1^{2x-1}\right) \\ & + \&c. \end{aligned} \right] \end{aligned}$$

(100.) From this formula to deduce $B_1, B_3, B_5, \&c.$; first make $x = 1$;

$$\begin{aligned} \therefore B_1 &= \frac{2}{4 \cdot 3} \cdot \left\{ 1 - (2 - 2) + \left(3 - 2 + 2 \cdot \frac{1}{2}\right) \right. \\ & \qquad \qquad \qquad \left. + (4 - 2 \cdot 3 + 1) - \&c. \right\} \\ &= \frac{1}{6}. \end{aligned}$$

Make $x = 2$;

$$\begin{aligned} \therefore B_3 &= \frac{-4}{16 \cdot 15} \{ 1 - (2^3 - 4) + (3^3 - 4 \cdot 2^3 + 6) \\ & \qquad \qquad \qquad - (4^3 - 4 \cdot 3^3 + 6 \cdot 2^3 - 4) \\ & \qquad \qquad \qquad + (5^3 - 4 \cdot 4^3 + 6 \cdot 3^3 - 4 \cdot 2^3 + 1) \\ & \qquad \qquad \qquad - \&c.; \end{aligned}$$

and, as every term of the form

$$z^n - 4(z-1)^n + 6(z-2)^n - 4(z-3)^n + (z-4)^n$$

is (when z is greater than n) necessarily $= 0$,

$$\therefore B_3 = -\frac{1}{60} \{ 1 - 4 + 1 \} = \frac{2}{60} = \frac{1}{30}.$$

Similarly, $B_5 = \frac{1}{42}.$

(101.) By substitution may other terms of the coefficients $B_1, B_3, B_5, \&c.$ be found; and we here subjoin the first ten numbers of Bernoulli expressed decimally and fractionally.

$$B_1 = 0.166666666666 = \frac{1}{6}$$

$$B_3 = 0.03333333333333 = \frac{1}{30}$$

$$B_5 = 0.0238095238095 = \frac{1}{42}$$

$$B_7 = 0.03333333333333 = \frac{1}{30}$$

$$B_9 = 0.075757575757575 = \frac{5}{66}$$

$$B_{11} = 0.2531135531135 = \frac{691}{2730}$$

$$B_{13} = 1.1666666666666 = \frac{7}{6}$$

$$B_{15} = 7.0921568627451 = \frac{3617}{510}$$

$$B_{17} = 54.9711779448621 = \frac{43867}{798}$$

$$B_{19} = 529.1242424242424 = \frac{1222277}{2310}$$

(102.) The applications of these numbers are very numerous; but we have only room for one or two, and must refer the reader to Lacroix, and to Sir John Herschell's Collection of Examples of the Applications of the Calculus of Finite Differences.

These numbers occur when we wish to find the sum of such series as

$$\frac{1}{1^{2n}} + \frac{1}{2^{2n}} + \frac{1}{3^{2n}} + \frac{1}{4^{2n}} + \&c. \text{ to infinity}$$

$$\frac{1}{1^{2n}} + \frac{1}{3^{2n}} + \frac{1}{5^{2n}} + \frac{1}{7^{2n}} + \&c.$$

It is well known that we may express $\sin \theta$ and $\cos \theta$ by means of the products

$$\sin \theta = \theta \left(1 - \frac{\theta^2}{\pi^2}\right) \left(1 - \frac{\theta^2}{2^2 \pi^2}\right) \left(1 - \frac{\theta^2}{3^2 \pi^2}\right) \left(1 - \frac{\theta^2}{4^2 \pi^2}\right) \dots$$

and

$$\cos \theta = \left(1 - \frac{2^2 \theta^2}{\pi^2}\right) \cdot \left(1 - \frac{2^2 \theta^2}{3^2 \pi^2}\right) \cdot \left(1 - \frac{2^2 \theta^2}{5^2 \pi^2}\right) \left(1 - \frac{2^2 \theta^2}{7^2 \pi^2}\right) \&c.;$$

or, writing $\pi \theta$ and $\frac{\pi}{2} \theta$ instead of θ ,

$$\sin \pi \theta = \pi \cdot \theta \left(1 - \frac{\theta^2}{1^2}\right) \left(1 - \frac{\theta^2}{2^2}\right) \left(1 - \frac{\theta^2}{3^2}\right) \left(1 - \frac{\theta^2}{4^2}\right) \&c.$$

$$\cos \left(\frac{\pi}{2} \theta\right) = \left(1 - \frac{\theta^2}{1^2}\right) \cdot \left(1 - \frac{\theta^2}{3^2}\right) \left(1 - \frac{\theta^2}{5^2}\right) \left(1 - \frac{\theta^2}{7^2}\right) \&c.$$

Taking the logarithm of the first expression, and then its differential coefficient, we have

$$\begin{aligned} \pi \cot \pi \theta &= \frac{1}{\theta} - \left\{ \frac{\frac{2\theta}{1^2}}{1 - \frac{\theta^2}{1^2}} + \frac{\frac{2\theta}{2^2}}{1 - \frac{\theta^2}{2^2}} + \frac{\frac{2\theta}{3^2}}{1 - \frac{\theta^2}{3^2}} + \&c. \right\} \\ &= \frac{1}{\theta} - \frac{2\theta}{1^2} \left\{ 1 + \frac{\theta^2}{1^2} + \frac{\theta^4}{1^4} + \frac{\theta^6}{1^6} + \&c. + \frac{\theta^{2x-2}}{1^{2x-2}} + \&c. \right\} \\ &\quad - \frac{2\theta}{2^2} \left\{ 1 + \frac{\theta^2}{2^2} + \frac{\theta^4}{2^4} + \frac{\theta^6}{2^6} + \&c. + \frac{\theta^{2x-2}}{2^{2x-2}} + \&c. \right\} \\ &\quad - \&c.; \end{aligned}$$

in which it is obvious that the coefficient of θ^{2x-1} will be

$$-2 \left\{ \frac{1}{1^{2x}} + \frac{1}{2^{2x}} + \frac{1}{3^{2x}} + \frac{1}{4^{2x}} + \frac{1}{5^{2x}} + \&c. \right\}.$$

But

$$\begin{aligned} \pi \cot \pi \theta &= \pi \cdot \sqrt{-1} \cdot \left\{ \frac{e^{\pi \theta \sqrt{-1}} + e^{-\pi \theta \sqrt{-1}}}{e^{\pi \theta \sqrt{-1}} - e^{-\pi \theta \sqrt{-1}}} \right\} = \pi \sqrt{-1} \left\{ \frac{e^{2\pi \theta \sqrt{-1}} + 1}{e^{2\pi \theta \sqrt{-1}} - 1} \right\} \\ &= \pi \sqrt{-1} \left\{ 1 + \frac{2}{e^{2\pi \theta \sqrt{-1}} - 1} \right\}; \end{aligned}$$

$\therefore$ the coefficient of θ^{2x-1} will be the same as that of the same power of t in the developement of $\frac{1}{e^t - 1}$.

Calculus of
Finite
Differences.

or of t^{2x} in the developement of $\frac{t}{t^2-1}$, multiplied by $2\pi\sqrt{-1} \cdot (2\pi\sqrt{-1})^{2x-1}$, or $(2\pi\sqrt{-1})^{2x}$, or $(-1)^x \cdot (2\pi)^{2x}$; and is consequently represented by

Calculus of
Finite
Differences.

$$\begin{aligned} (-1)^x \cdot (2\pi)^{2x} b_{2x} &= (-1)^x \cdot (2\pi)^{2x} (-1)^{x+1} \cdot \frac{B_{2x-1}}{1 \cdot 2 \cdot 3 \dots 2x} \\ &= - \frac{2^{2x} \cdot \pi^{2x}}{1 \cdot 2 \cdot 3 \dots (2x)} \cdot B_{2x-1}. \end{aligned}$$

Equating these coefficients of θ^{2x-1} , we obtain

$$\frac{1}{1^{2x}} + \frac{1}{2^{2x}} + \frac{1}{3^{2x}} + \frac{1}{4^{2x}} + \&c. = \frac{2^{2x-1} \cdot \pi^{2x}}{1 \cdot 2 \cdot 3 \dots (2x)} \cdot B_{2x-1};$$

whence, making $x = 1, 2, 3, 4$, we have the values of the following series:

$$\begin{aligned} \frac{1}{1^2} + \frac{1}{2^2} + \frac{1}{3^2} + \frac{1}{4^2} + \frac{1}{5^2} + \&c. &= \frac{\pi^2}{6} \\ \frac{1}{1^4} + \frac{1}{2^4} + \frac{1}{3^4} + \frac{1}{4^4} + \frac{1}{5^4} + \&c. &= \frac{\pi^4}{90} \\ \frac{1}{1^6} + \frac{1}{2^6} + \frac{1}{3^6} + \frac{1}{4^6} + \frac{1}{5^6} + \&c. &= \frac{\pi^6}{945} \\ \frac{1}{1^8} + \frac{1}{2^8} + \frac{1}{3^8} + \frac{1}{4^8} + \frac{1}{5^8} + \&c. &= \frac{\pi^8}{1350} \end{aligned}$$

(103.) Again, taking the logarithms of $\cos \frac{\pi\theta}{2}$, and of the factors to which it is equal, and then their differential coefficients, we find that

$$-\frac{\pi}{2} \tan \frac{\pi\theta}{2} = \frac{-\frac{2\theta}{1^2}}{1 - \frac{\theta^2}{1^2}} + \frac{-\frac{2\theta}{3^2}}{1 - \frac{\theta^2}{3^2}} + \frac{-\frac{2\theta}{5^2}}{1 - \frac{\theta^2}{5^2}} + \frac{-\frac{2\theta}{7^2}}{1 - \frac{\theta^2}{7^2}} + \&c.;$$

and the coefficient of θ^{2x-1} , by dividing out the fractions, will be found to be

$$-2 \left\{ \frac{1}{1^{2x}} + \frac{1}{3^{2x}} + \frac{1}{5^{2x}} + \frac{1}{7^{2x}} + \&c. \right\}.$$

But

$$\begin{aligned} -\frac{\pi}{2} \tan \frac{\pi\theta}{2} &= \frac{-\pi}{2\sqrt{-1}} \frac{e^{\frac{\pi\theta}{2}\sqrt{-1}} - e^{-\frac{\pi\theta}{2}\sqrt{-1}}}{e^{\frac{\pi\theta}{2}\sqrt{-1}} + e^{-\frac{\pi\theta}{2}\sqrt{-1}}} = \frac{-\pi}{2\sqrt{-1}} \left(\frac{e^{\pi\theta\sqrt{-1}} - 1}{e^{\pi\theta\sqrt{-1}} + 1} \right) \\ &= \frac{-\pi}{2\sqrt{-1}} \left(1 - \frac{2}{e^{\pi\theta\sqrt{-1}} + 1} \right); \end{aligned}$$

and, as we have said before, the coefficient of θ^{2x-1} will be the same as that of the same power of t in the expansion of $\frac{1}{e^t+1}$, or of t^{2x} in the expansion of $\frac{t}{t^2+1}$, but multiplied by $\frac{\pi}{\sqrt{-1}} \cdot (\pi\sqrt{-1})^{2x-1}$, or $(-1)^{x-1} \cdot \pi^{2x}$; and $\therefore$ the coefficient of $\theta^{2x-1} = (-1)^{x-1} \cdot \pi^{2x} \cdot a_{2x}$

$$\begin{aligned} &= (-1)^{x-1} \cdot \pi^{2x} \cdot \frac{(2^{2x} - 1)}{(-1)^x \cdot 1 \cdot 2 \cdot 3 \dots (2x)} \cdot B_{2x-1} \\ &= - \frac{(2^{2x} - 1) \cdot \pi^{2x}}{1 \cdot 2 \cdot 3 \cdot 4 \dots 2x} \cdot B_{2x-1}; \end{aligned}$$

and equating these coefficients of θ^{2x-1} we have

$$\frac{1}{1^{2x}} + \frac{1}{3^{2x}} + \frac{1}{5^{2x}} + \frac{1}{7^{2x}} + \&c. = \frac{1}{2} \cdot \frac{(2^{2x} - 1) \cdot \pi^{2x}}{1 \cdot 2 \cdot 3 \dots 2x} B_{2x-1},$$

whence

$$\begin{aligned} \frac{1}{1^2} + \frac{1}{3^2} + \frac{1}{5^2} + \frac{1}{7^2} + \&c. &= \frac{\pi^2}{8} \\ \frac{1}{1^4} + \frac{1}{3^4} + \frac{1}{5^4} + \frac{1}{7^4} + \&c. &= \frac{\pi^4}{96} \\ \frac{1}{1^6} + \frac{1}{3^6} + \frac{1}{5^6} + \frac{1}{7^6} + \&c. &= \frac{\pi^6}{960}. \end{aligned}$$

Calculus of
Finite
Differences.

(104.) Since also the series

$$\frac{1}{1^{2x}} - \frac{1}{2^{2x}} + \frac{1}{3^{2x}} - \frac{1}{4^{2x}} + \frac{1}{5^{2x}} - \frac{1}{6^{2x}} + \&c.$$

may be resolved into the two series

$$\frac{1}{1^{2x}} + \frac{1}{3^{2x}} + \frac{1}{5^{2x}} + \&c. - \left(\frac{1}{2^{2x}} + \frac{1}{4^{2x}} + \frac{1}{6^{2x}} + \&c. \right),$$

or into

$$\frac{1}{1^{2x}} + \frac{1}{3^{2x}} + \frac{1}{5^{2x}} + \&c. - \frac{1}{2^{2x}} \left\{ \frac{1}{1^{2x}} + \frac{1}{2^{2x}} + \frac{1}{3^{2x}} + \&c. \right\};$$

therefore the sum of the series will be expressed by

$$\begin{aligned} & \frac{1}{2} \frac{2^{2x} - 1}{1 \cdot 2 \cdot 3 \dots 2x} \cdot B_{2x-1} - \frac{1}{2^{2x}} \cdot \frac{2^{2x-1} \cdot \pi^{2x}}{1 \cdot 2 \cdot 3 \dots 2x} \cdot B_{2x-1} \\ &= \frac{1}{2} \cdot \frac{(2^{2x} - 2) \pi^{2x}}{1 \cdot 2 \cdot 3 \dots 2x} \cdot B_{2x-1} = \frac{(2^{2x-1} - 1) \pi^{2x}}{1 \cdot 2 \cdot 3 \dots 2x} B_{2x-1}; \end{aligned}$$

thence

$$\frac{1}{1^2} - \frac{1}{2^2} + \frac{1}{3^2} - \frac{1}{4^2} + \frac{1}{5^2} - \frac{1}{6^2} + \&c. = \frac{\pi^2}{12}$$

and

$$\frac{1}{1^4} - \frac{1}{2^4} + \frac{1}{3^4} - \frac{1}{4^4} + \frac{1}{5^4} - \frac{1}{6^4} + \&c. = \frac{7 \cdot \pi^4}{720}.$$

We must again refer the reader to Herschell's Examples for many curious applications of these numbers to the summation of series. Without these examples he cannot enter fully into the spirit of the inquiries of this branch of analysis, or form any conception of its extent or power.

 (105.) The expression for the integral of u_x , or

$$\Sigma u_x = \int u_x dx - \frac{u_x}{2} + \frac{B_1}{2} \cdot \frac{d \cdot u_x}{dx} - \frac{B_3}{2 \cdot 3 \cdot 4} \cdot \frac{d^3 u_x}{dx^3} + \frac{B_5}{2 \cdot 3 \cdot 4 \cdot 5 \cdot 6} \cdot \frac{d^5 u_x}{dx^5} - \&c.$$

is very useful in determining the approximate values of some numerical expressions which it would be difficult, perhaps impossible, to arrive at by other means.

First, let $u_x = \frac{1}{x}$; then, as we shall hereafter show, if u_x be the general term of a series, Σu_{x+1} corrected is the value of the series itself, $\therefore \Sigma \left(\frac{1}{x} \right)$ is the representative of the series

$$\begin{aligned} & \frac{1}{1} + \frac{1}{2} + \frac{1}{3} + \frac{1}{4} + \&c. + \frac{1}{x-1} \\ &= \left(\frac{1}{1} + \frac{1}{2} + \frac{1}{3} + \&c. + \frac{1}{x} \right) - \frac{1}{x} = S \left(\frac{1}{x} \right) - \frac{1}{x}, \end{aligned}$$

where $S \left(\frac{1}{x} \right)$ represents the sum of the series, of which the last term is $\frac{1}{x}$;

$$\therefore S \left(\frac{1}{x} \right) = C + \log x + \frac{1}{2x} - \frac{B_1}{2x^2} + \frac{B_3}{4x^4} - \frac{B_5}{6x^6} + \&c.;$$

a series which is the more convergent the greater x is: it remains to determine the constant.

We cannot suppose $x = 0$, $\therefore -\log 0 = \infty$ and the other terms are also infinite; but let $x = 1$,

$$\therefore S \left(\frac{1}{1} \right) = 1;$$

$$\therefore 1 = C + \frac{1}{2} - \frac{B_1}{2} + \frac{B_3}{4} - \frac{B_5}{6} + \&c$$

$$\therefore C = \frac{1}{2} + \frac{B_1}{2} - \frac{B_3}{4} + \frac{B_5}{6} - \&c.$$

This series is only convergent for the first few terms for $B_{12} = \frac{7}{6}$, and afterwards the numbers of Bernoulli increase rapidly; but as the terms are alternately $+$ and $-$, the difference between two consecutive terms may decrease, and as we shall have the value of C successively greater or less than its true value, according as we stop at a positive or at a negative term, we may assume the value of C to be very near its real value when the differences diminish and are small.

Then successively putting for B_1, B_3, B_5, B_7 , their values $\frac{1}{6}, \frac{1}{30}, \frac{1}{42}, \frac{1}{30}$, we have

 Calculus of
Finite
Differences.

$$\begin{aligned}
 C &> \frac{1}{2} &< \frac{1}{2} + \frac{1}{12} && \text{or } > .50000 < .58333 \\
 .58333 - \frac{1}{120} &< .58333 - \frac{1}{120} + \frac{1}{252} && \text{or } > .57500 < .57896 \\
 > .57896 - \frac{1}{240} && \text{i.e. } > .57480.
 \end{aligned}$$

Hence, since .57500 and .57480 are decreasing, we may stop at .57896 as an approximate value for C ; or by taking an arithmetic mean between .57500 and .57896, $C = .57698$.

If we make $x = 10$, and let A represent the sum of

$$\begin{aligned}
 \frac{1}{1} + \frac{1}{2} + \frac{1}{3} + \frac{1}{4} + \&c. + \frac{1}{10} = 2.928968253968 \\
 C = A - \log 10 - \frac{1}{20} + \frac{B_1}{200} - \frac{B_3}{40000} + \&c. = .5772156649015329,
 \end{aligned}$$

by computing as far as the 11th term of the series.

(106.) Let the value of $S\left(\frac{1}{x}\right)$ be required to 1000 terms, in which case it is sufficient to calculate the first four terms of the expansion for $S\left(\frac{1}{x}\right)$, or make

$$S\left(\frac{1}{x}\right) = C + \log 1000 + \frac{1}{2000} - \frac{B_1}{2(1000)^2} + \frac{B_3}{4(1000)^4}$$

Now

$$\begin{aligned}
 C &= .5772156649015 \\
 \log 1000 &= 6.9077552789821 \\
 \frac{1}{2000} &= .0005000000000 \\
 &\quad \underline{7.4854709438836} \\
 \frac{B_1}{2x^2} &= 0.0000000833333 \\
 &\quad \underline{}
 \end{aligned}$$

$$\therefore \frac{1}{1} + \frac{1}{2} + \frac{1}{3} + \&c. + \frac{1}{1000} = 7.4854708605503$$

$\frac{B_3}{4(1000)^4}$ is neglected, as there are 13 ciphers after the decimal point.

(107.) Next to find the value of $\sum u_x$, when u_x is the logarithm of x .

$$\begin{aligned}
 \therefore \sum \log(x) &= \int \log \cdot x \cdot dx - \frac{\log x}{2} + \frac{B_1}{1 \cdot 2} \cdot \frac{d \cdot \log(x)}{dx} - \frac{B_3}{2 \cdot 3 \cdot 4} \cdot \frac{d^3 \cdot \log(x)}{dx^3} + \&c. \\
 &= x \log x - x - \frac{\log(x)}{2} + \frac{B_1}{1 \cdot 2} \cdot \frac{1}{x} - \frac{B_3}{3 \cdot 4 \cdot x^3} + \&c. + C \\
 &= \left(x - \frac{1}{2}\right) \log x - x + \frac{B_1}{2x} - \frac{B_3}{3 \cdot 4 \cdot x^3} + \&c. + C \\
 \therefore S(\log x) &= \left(x + \frac{1}{2}\right) \log x - x + \frac{B_1}{2x} - \frac{B_3}{3 \cdot 4 \cdot x^3} + \&c. + C
 \end{aligned}$$

If we make $x = 10$, and calculate the first ten numbers of the series, and then add the Napierian logarithms of first ten numbers together, we shall find that

$$C = .9189385332047.$$

(108.) But the actual value of C may be found in the following manner:

since

$$S(\log \cdot x) = \log 1 + \log 2 + \log 3 \dots + \log x = \log(1 \cdot 2 \cdot 3 \dots x);$$

$$\therefore \log(1 \cdot 2 \cdot 3 \dots x) = \left(x + \frac{1}{2}\right) \log x - x + \frac{B_1}{2x} - \frac{B_3}{3 \cdot 4 \cdot x^3} + \&c. + C.$$

And to find C let x become infinite;

$$\therefore \log(1 \cdot 2 \cdot 3 \dots x) = \left(x + \frac{1}{2}\right) \log x - x + C \quad (1)$$

$$\therefore \log(1 \cdot 2 \cdot 3 \dots 2x) = \left(2x + \frac{1}{2}\right) \log 2x - 2x + C \quad (2).$$

$$\begin{aligned}
 \text{But } \log(2 \cdot 4 \cdot 6 \cdot 8 \dots 2x) &= \log 2^x \cdot (1 \cdot 2 \cdot 3 \cdot 4 \dots x) = \log 2^x + \log(1 \cdot 2 \cdot 3 \dots x) \\
 &= x \log 2 + \log(1 \cdot 2 \cdot 3 \dots x) = x \log 2 + \left(x + \frac{1}{2}\right) \log x - x + C \quad (3).
 \end{aligned}$$

Calculus of Finite Differences. Now subtract equation (3) from equation (2);

$$\therefore \log 1 \cdot 3 \cdot 5 \cdot 7 \dots 2x-1 = x \log x + \left(x + \frac{1}{2}\right) \log 2 - x \quad (4).$$

Then subtract equation (4) from equation (3);

$$\therefore \log \frac{2 \cdot 4 \cdot 6 \cdot 8 \dots 2x}{1 \cdot 3 \cdot 5 \cdot 7 \dots 2x-1} = \frac{1}{2} \log x - \frac{1}{2} \log 2 + C = \frac{1}{2} \log 2x - \log 2 + C;$$

$$\begin{aligned} \therefore 2C - 2 \log 2 &= 2 \log \frac{2 \cdot 4 \cdot 6 \dots 8 \dots 2x}{1 \cdot 3 \cdot 5 \dots 7 \dots 2x-1} - \log 2x \\ &= \log \frac{2^2 \cdot 4^2 \cdot 6^2 \cdot 8^2 \dots (2x)^2}{1 \cdot 3^2 \cdot 5^2 \cdot 7^2 \dots (2x-1)^2} - \log 2x \\ &= \log \frac{2^2 \cdot 4^2 \cdot 6^2 \cdot 8^2 \dots (2x)^2}{1 \cdot 3^2 \cdot 5^2 \cdot 7^2 \dots (2x-1)^2 \cdot 2x} \end{aligned}$$

or since $\frac{1}{2x}$ and $\frac{1}{2x+1}$ are the same when x is very great,

$$\therefore 2C - 2 \log 2 = \log \frac{2^2 \cdot 4^2 \cdot 6^2 \cdot 8^2 \dots (2x)^2}{1 \cdot 3^2 \cdot 5^2 \cdot 7^2 \cdot 9^2 (2x-1)^2 (2x+1)^2}.$$

But by Wallis's theorem,

$$\frac{\pi}{2} = \frac{2 \cdot 2 \cdot 4 \cdot 4 \cdot 6 \cdot 6 \cdot 8 \cdot 8 \cdot 10 \cdot 10 \dots}{1 \cdot 3 \cdot 3 \cdot 5 \cdot 5 \cdot 7 \cdot 7 \cdot 9 \cdot 9 \cdot 11 \dots};$$

$$\therefore 2C - 2 \log 2 = \log \frac{\pi}{2} = \log \pi - \log 2;$$

$$\therefore 2C = \log \pi + \log 2 = \log 2\pi; \therefore C = \frac{1}{2} \log 2\pi = \log \sqrt{2\pi};$$

whence

$$S(\log x) = \log \sqrt{2\pi} + \left(x + \frac{1}{2}\right) \log x - x + \frac{B_1}{2x} - \frac{B_3}{3 \cdot 4x^3} + \&c.$$

(109.) If x be very great, so that $\frac{B_1}{2x}$, $\frac{B_3}{3 \cdot 4x^3}$, &c. may be neglected,

$$\begin{aligned} \therefore \log (1 \cdot 2 \cdot 3 \dots x) &= \log \sqrt{2\pi} + \left(x + \frac{1}{2}\right) \log x - x \\ &= \log \sqrt{2\pi} \cdot x^{x+\frac{1}{2}} - x; \end{aligned}$$

$$\begin{aligned} \therefore 1 \cdot 2 \cdot 3 \dots x &= e^{-x+\log \sqrt{2\pi} \cdot x^{x+\frac{1}{2}}} = \sqrt{2\pi} x^{x+\frac{1}{2}} e^{-x} \\ &= \sqrt{2\pi x} \cdot \left(\frac{x}{e}\right)^x. \end{aligned}$$

If x be not so large as to allow all the inverse powers of x to be neglected, we shall have

$$\log \frac{1 \cdot 2 \cdot 3 \dots x}{\sqrt{2\pi} \cdot x^{x+\frac{1}{2}}} = -x + \frac{B_1}{2x} - \frac{B_3}{3 \cdot 4x^3} + \&c.;$$

$$\therefore 1 \cdot 2 \cdot 3 \dots x = \sqrt{2\pi} \cdot x^{x+\frac{1}{2}} \cdot e^{-x} e^{\frac{B_1}{2x} - \frac{B_3}{3 \cdot 4x^3} + \&c.}$$

$$= \sqrt{2\pi x} \left(\frac{x}{e}\right)^x \cdot e^{\frac{1}{12x} - \frac{1}{360x^3} + \&c.}$$

$$= \sqrt{2\pi x} \cdot \left(\frac{x}{e}\right)^x \cdot \left\{1 + \frac{1}{12x} + \frac{1}{288x^2} + \&c.\right\};$$

which reduces itself to the preceding value when by making x so great the terms $\frac{1}{12x}$, $\frac{1}{288x^2}$, &c. become so small as to be inappreciable.

(110.) But when x is considerable, the formula $\sqrt{2\pi x} \cdot \left(\frac{x}{e}\right)^x$ is sufficiently accurate.

Thus if it be required to find the product of the first 1000 numbers;

$$\therefore 1 \cdot 2 \cdot 3 \dots 1000 = \sqrt{2\pi \cdot 1000} \cdot \left(\frac{1000}{e}\right)^{1000}.$$

Calculus of Finite Differences.

Calculus of
Finite
Differences.

Now

$$\begin{aligned}\log \sqrt{2\pi} \cdot 1000 &= 1.8990899 \\ 1000 \cdot \log(1000) &= 3000.000000 \\ &\quad \underline{3001.8990899} \\ 1000 \log e &= 434.2944819\end{aligned}$$

$$\therefore \log(1 \cdot 2 \cdot 3 \dots 1000) = 2567.6046080;$$

and thus the product $1 \cdot 2 \cdot 3 \dots 1000$ will form a number consisting of 2568 figures, the first to the left being 4023537, followed by 2561 ciphers.

If the number be computed by the formula

$$\log 1 \cdot 2 \cdot 3 \dots 1000 = \log \sqrt{2\pi} x + x \log x - Mx + \frac{M B_1}{2x} - \frac{M \cdot B_3}{2 \cdot 4 x^3},$$

where M is the modulus and the logarithms are the ordinary ones, the result will be

$$\log 1 \cdot 2 \cdot 3 \dots 1000 = 2567.6046442;$$

and as .6046442 is the logarithm of 4.02387, the number will have its first six figures expressed by 402387, and these will be succeeded by 2562 ciphers.

The difference between the results obtained by the formula $\sqrt{2\pi} x \left(\frac{x}{e}\right)^x$, and that from the theorem in which the terms involving B_1 and B_3 are not neglected will obviously become smaller as x increases; yet the first formula is sufficiently accurate when the ratios only of high numbers are required.

(111.) The product of the odd numbers is very easily found from the previous investigation; for

$$\begin{aligned}\log 1 \cdot 3 \cdot 5 \dots 2x-1 &= x \log x + \left(x + \frac{1}{2}\right) \log 2 - x \\ &= x \log 2x + \frac{1}{2} \log 2 - x \\ &= \log (2x)^x \cdot 2^{\frac{1}{2}} - x; \\ \therefore \log \frac{1 \cdot 3 \cdot 5 \dots 2x-1}{(2x)^x \cdot \sqrt{2}} &= -x; \\ \therefore 1 \cdot 3 \cdot 5 \dots 2x-1 &= (2x)^x \sqrt{2} \cdot e^{-x} = \sqrt{2} \cdot \left(\frac{2x}{e}\right)^x.\end{aligned}$$

Integration of Equations of Differences.

(112.) Hitherto we have only examined the cases in which the function may be integrated when the difference is given explicitly in terms of x : we proceed to show how the integrations are to be performed when the differences and the functions are involved together.

In such a case the proposed equation will be comprised under the general formula

$$F(x, u_x, u_{x+1}, \&c., \Delta \cdot u_x, \Delta^2 \cdot u_x, \Delta^3 \cdot u_x, \&c.) = 0.$$

But since we can express $\Delta \cdot u_x, \Delta^2 \cdot u_x, \&c.$ in terms of u_x and its successive values, this function will not lose any of its generality if we substitute for $\Delta \cdot u_x, \Delta^2 \cdot u_x, \&c.$ their values in terms of $u_x, u_{x+1}, \&c.$, and write the equation under the form

$$F(x, u_x, u_{x+1}, u_{x+2}, \dots, u_{x+n}) = 0.$$

(113.) We divide equations of differences into orders: those involving $\Delta \cdot u_x$ only are called equations of the first order; and when $\Delta^2 \cdot u_x$ and $\Delta \cdot u_x$ enter into the expression, it is styled an equation of the second order, and so on; or otherwise equations involving u_{x+1} and u_x are equations of the first order, and $f(u_{x+2}, u_{x+1}, u_x) = 0$ is an equation of the second order; and, in general, the equation $f(x, u_x, u_{x+1}, \dots, u_{x+n}) = 0$ is of the n th order; and it is obvious that every equation of finite differences when solved will give the form of a series, and as, when u_x is known, any term is known, hence any particular term will be a function of some of the terms which precede it, and of the index of its place in the series.

(114.) We might infer from what has been previously said respecting the integration of differential equations, that the integration of an equation of finite differences of (n) dimensions would introduce into the solution as many arbitrary constants as there have been integrations, or as many as the order of the equation indicates. But that the general equation $f(x, u_x, u_{x+1}, \dots, u_{x+n}) = 0$ will, under its most complete form, include (n) constants, may be thus shown.

Suppose u_x to contain besides x , (n) constant quantities, $a', a'', a''' \dots a^n$, so that

$$u_x = f(x, a', a'', a''' \dots a^n).$$

Then, writing $x+1, x+2, x+3 \dots x+n$ for x , we may form the equations

Calculus of
Finite
Differences.

Calculus of
Finite
Differences.

$$\begin{aligned} u_{x+1} &= f(x+1, a', a'', a''' \dots a^n) \\ u_{x+2} &= f(x+2, a', a'', a''' \dots a^n) \\ u_{x+3} &= f(x+3, a', a'', a''' \dots a^n) \\ &\vdots \\ u_{x+n} &= f(x+n, a', a'', a''' \dots a^n). \end{aligned}$$

 Calculus of
Finite
Differences.

And each of these equations hold good simultaneously, and their number is $n+1$; hence between them the (n) quantities $a', a'', a''' \dots a^n$ may be eliminated, and we shall have at length the equation

$$f(x, u_x, u_{x+1}, u_{x+2}, u_{x+3} \dots u_{x+n}) = 0$$

entirely independent of them. Hence, conversely, as every equation of (n) dimensions in its most general form may be supposed to be derived in the manner just explained, we must, in reascending to the primitive integral, introduce (n) constant quantities.

(115.) And as in differential equations, so in equations of differences will there be particular solutions, but with this difference, that these solutions may in some cases be derived, which will contain as many arbitrary constants as the complete integral itself. This will appear from the circumstance, that the constant need not necessarily be independent of x , and therefore its determination, in order to free the equation from it, may introduce arbitrary constants.

(116.) We now proceed to the integration of equations of differences, beginning with the most simple case, and then ascending to the general theory of such equations. But we shall soon find that the number of cases which can be integrated is very limited, and that the general methods frequently involve the analyst in difficulties greater than those which the original equation presents, and that the solutions of many of the equations depend upon his individual dexterity.

(117.) To integrate the equation of the first degree and of the first order,

$$\Delta u_x + P_x u_x = Q_x,$$

where P and Q involve x only.

This equation is analogous to that of the first degree and first order, $dy + Py dx = Q dx$, and its integral may be found in a similar manner.

Thus, let

$$u_x = v_x \cdot z_x; \therefore \Delta u_x = v_x \Delta z_x + z_x \cdot \Delta v_x + \Delta v_x \cdot \Delta z_x;$$

$\therefore$ substituting in the original equation, we have

$$z_x \cdot (\Delta v_x + P_x \cdot v_x) + v_x \cdot \Delta z_x + \Delta v_x \cdot \Delta z_x = Q_x;$$

and making

$$\Delta \cdot v_x + P_x \cdot v_x = 0, \text{ and } \therefore v_x \Delta z_x + \Delta v_x \cdot \Delta z_x = Q_x,$$

$$\therefore \frac{\Delta v_x}{v_x} = -P_x \text{ and } \Delta z_x = \frac{Q_x}{v_x + \Delta v_x} = \frac{Q_x}{v_{x+1}}$$

But since P_x is a function of x only, make $v_x = e^t$ where t is a function of x only;

$$\therefore \Delta v_x = e^{t+\Delta t} - e^t = e^t (e^{\Delta t} - 1);$$

$$\therefore \frac{\Delta \cdot v_x}{v_x} = -P_x = e^{\Delta t} - 1;$$

$$\therefore e^{\Delta t} = 1 - P_x; \therefore \Delta t = \log(1 - P_x) \text{ and } t = \Sigma \log(1 - P_x).$$

But the sum of the logarithm of $(1 - P_x)$ expresses the sum of all the terms arising from giving to x all the values between the assumed limits, and as the sum of any number of logarithms is equal to the logarithm of their product, we may express this product by $[1 - P_{x-1}]^x$, where $(1 - P_{x-1})$ represents the last term, and the index x expresses the number of the terms $(1 - P_0), (1 - P_1), (1 - P_2), \&c$ in the product, and $\therefore t = \log[1 - P_{x-1}]^x$.

Hence

$$\therefore e^{\log w} = w, \therefore e^t = [1 - P_{x-1}]^x = v_x;$$

$$\therefore z_x = \Sigma \left(\frac{Q_x}{v_{x+1}} \right) + C = \Sigma \left(\frac{Q_x}{[1 - P_x]^{x+1}} \right) + C;$$

$$\therefore u_x = z_x v_x = [1 - P_{x-1}]^x \left\{ \Sigma \frac{Q_x}{[1 - P_x]^{x+1}} + C \right\};$$

whence u_x is known, or the general term of a series is found.

(118.) The method which is generally adopted in the solution of this equation, and which is derived from the preceding investigation, is the following.

Substituting $u_{x+1} - u_x$ for Δu_x , we have

$$u_{x+1} - (1 - P_x) u_x = Q_x;$$

or $u_{x+1} - A_x u_x = Q_x$, where A_x is put for $1 - P_x$.

Assume

$$u_x = A_0 A_1 A_2 A_3 \dots A_{x-1} v_x;$$

$$\therefore u_{x+1} = A_0 A_1 A_2 A_3 \dots A_x v_{x+1};$$

$$\therefore u_{x+1} - A_x u_x = A_0 A_1 A_2 A_3 \dots A_x \{v_{x+1} - v_x\} = Q_x;$$

or

$$A_0 \cdot A_1 \cdot A_2 \cdot A_3 \dots A_x \cdot \Delta v_x = Q_x;$$

Calculus of
Finite
Differences.

Calculus of
Finite
Differences.

$$\therefore v_x = \Sigma \left(\frac{Q_x}{A_0 A_1 \dots A_x} \right) + C;$$

$$\therefore u_x = A_0 A_1 \dots A_{x-1} v_x = A_0 A_1 \dots A_{x-1} \left\{ \Sigma \left(\frac{Q_x}{A_1 A_2 \dots A_x} \right) + C \right\};$$

which may be written as in the preceding article

$$u_x = [A_{x-1}]^x \left\{ \Sigma \frac{Q_x}{[A_x]^{x+1}} + C \right\}.$$

Instead, however, of using the notation $[A_{x-1}]^x$ to represent the product of the x factors $A_0 A_1 A_2 \dots A_{x-1}$, Sir John Herschell has proposed to write it $P \cdot A_{x-1}$, P indicating product, and A_{x-1} the last term.

Thus $[A_x]^{x+1}$ will be expressed by $P \cdot A_x$, and thus

$$u_x = P A_{x-1} \left\{ \Sigma \frac{Q_x}{P \cdot A_x} + C \right\}.$$

We shall refer to this expression in the succeeding articles.

Cor. (1.) If the coefficient of u_x be constant and $= A$, then

$$A_0 \cdot A_1 \cdot A_2 \cdot A_3 \dots A_{x-1} = A^x;$$

$$\therefore u_x = A^x \cdot v_x$$

$$u_{x+1} = A^{x+1} v_{x+1};$$

$$\therefore u_{x+1} - A u_x = A^{x+1} \cdot (v_{x+1} - v_x) = A^{x+1} \Delta v_x = Q_x;$$

$$\therefore \Delta(v_x) = \frac{Q_x}{A \cdot A^x}; \therefore v_x = \frac{1}{A} \cdot \left\{ \Sigma \left(\frac{Q_x}{A^x} \right) + C \right\};$$

$$\therefore u_x = A^x v_x = A^{x-1} \cdot \left\{ \Sigma \left(\frac{Q_x}{A^x} \right) + C \right\}.$$

Cor. (2.) We must take care that A_x be not $= 0$, when $x = 0$; but if A_x does vanish when this substitution is made for x , we must omit the factor A_0 , and put $x = 1$.

Cor. (3.) If, when A_x is constant and $= A$, Q_x be also constant $= B$, the expressions for v_x and u_x are much simplified.

For then

$$v_x = \Sigma \frac{Q_x}{A_{x+1}} = \frac{B}{A} \Sigma \frac{1}{A^x} = \frac{B}{A} \cdot \frac{A}{1-A} \cdot \frac{1}{A^x} + C$$

$$= \frac{B}{(1-A) A^x} + C;$$

$$\therefore u_x = A^x v_x = \frac{B}{1-A} + C \cdot A^x.$$

(119.) We shall now give a few simple examples of the preceding formula.

Example (1.) Integrate $u_{x+1} - x + 1 u_x = 1 \cdot 2 \cdot 3 \dots x + 1$.

Here $A_x = x + 1$; $\therefore A_{x-1} = x$ and $Q_x = 1 \cdot 2 \cdot 3 \dots x + 1$.

$\therefore$ let

$$u_x = 1 \cdot 2 \cdot 3 \dots x \cdot v_x;$$

$$\therefore u_{x+1} = 1 \cdot 2 \cdot 3 \dots x + 1 \cdot v_{x+1};$$

$$\therefore u_{x+1} - x + 1 u_x = 1 \cdot 2 \cdot 3 \dots x + 1 \cdot \{v_{x+1} - v_x\} = 1 \cdot 2 \cdot 3 \dots x + 1;$$

$$\therefore v_{x+1} - v_x = \Delta \cdot v_x = 1; \therefore v_x = x + C;$$

$$\therefore u_x = 1 \cdot 2 \cdot 3 \dots x \cdot (x + C).$$

Example (2.) Let

$$u_{x+1} - \frac{x}{x+1} u_x = a \cdot \frac{2x+1}{x+1}.$$

Here

$$A_x = \frac{x}{x+1} \text{ and } A_{x-1} = \frac{x-1}{x}.$$

But $A_0 = 0$; and $\therefore$ we assume $u_x = A_1 A_2 \dots A_{x-1} \cdot v_x$;

$$\therefore u_x = \frac{1}{2} \cdot \frac{2}{3} \cdot \frac{3}{4} \dots \frac{x-2}{x-1} \cdot \frac{x-1}{x} v_x = \frac{1}{x} \cdot v_x;$$

$$\therefore u_{x+1} = \frac{1}{x+1} v_{x+1};$$

$$\therefore u_{x+1} - \frac{x}{x+1} u_x = \frac{1}{x+1} \cdot v_{x+1} - \frac{1}{x+1} v_x = \frac{1}{x+1} (v_{x+1} - v_x) = \frac{a \cdot 2x+1}{x+1};$$

$$\therefore \Delta \cdot v_x = 2ax + a; \therefore v_x = a \cdot x \cdot x - 1 + ax + C = ax^2 + C;$$

$$\therefore u_x = \frac{1}{x} v_x = ax + \frac{C}{x}.$$

Calculus of
Finite
Differences.

Example (3.) Integrate the equation $u_{x+1} = \overline{x+1} \cdot u_x$.

Here

$$u_{x+1} - \overline{x+1} \cdot u_x = 0,$$

and

$$A_0 = 1, A_{x-1} = x.$$

Let

$$\therefore u_x = 1 \cdot 2 \cdot 3 \dots x v_x;$$

$$\therefore u_{x+1} = 1 \cdot 2 \cdot 3 \dots \overline{x+1} v_{x+1};$$

$$\therefore u_{x+1} - \overline{x+1} u_x = 1 \cdot 2 \cdot 3 \dots \overline{x+1} \cdot (v_{x+1} - v_x) = 0;$$

$$\therefore \Delta v_x = 0; \therefore v_x = C,$$

and

$$u_x = 1 \cdot 2 \cdot 3 \dots x \cdot C.$$

But the following solution of the question will illustrate the general method:

As

$$u_{x+1} - u_x = x u_x;$$

$$\therefore \Delta u_x = x \cdot u_x.$$

Make

$$u_x = c \cdot e^t; \therefore \Delta u_x = c \cdot e^t \cdot (e^x - 1);$$

$$\therefore \frac{\Delta \cdot u_x}{u_x} = e^x - 1 = x;$$

$$\therefore e^x = 1 + x; \therefore \Delta \cdot t = \log(1 + x);$$

$$\therefore t = \sum \log(1 + x) = \log 1 + \log 2 + \log 3 + \&c. + \log x = \log(1 \cdot 2 \cdot 3 \dots x);$$

$$\therefore e^t = 1 \cdot 2 \cdot 3 \dots x,$$

and

$$u_x = c \cdot 1 \cdot 2 \cdot 3 \dots x.$$

This question is the solution of the problem, "Find the number of permutations which may be made of x things taken together." Here u_x represents the number required, while u_{x+1} will represent the number that can be formed of $x+1$ things; and as the new letter can be written in $x+1$ places, each of the former arrangements can be altered $x+1$ times, and therefore the whole number increased $x+1$ times.

Hence we derive the equation $u_{x+1} = \overline{x+1} u_x$.

And since, when

$$x = 1, u_1 = 1 = C; \therefore C = 1;$$

$$\therefore u_x = 1 \cdot 2 \cdot 3 \cdot 4 \dots \overline{x+1} \cdot x;$$

the same result as is obtained in ordinary algebra.

(120.) Next to integrate the equation of n dimensions,

$$u_{x+n} + A u_{x+n-1} + B u_{x+n-2} + C u_{x+n-3} + \&c. + M u_x + N = 0,$$

where $A, B, C, \&c. M$ and N are constant quantities.

Make

$$u_x = a^x + A_1; \therefore u_{x+n} = a^{x+n} + A_1;$$

and, substituting, the equation becomes

$$a^{x+n} + A a^{x+n-1} + B a^{x+n-2} + C a^{x+n-3} + \&c. + M a^x + A_1 \{1 + A + B + C + \&c. + M\} + N = 0;$$

and to determine A_1 , let

$$A_1 = \frac{-N}{1 + A + B + C + \&c. + M};$$

and $\therefore$ dividing by a^x , we have

$$a^n + A a^{n-1} + B a^{n-2} + C a^{n-3} + \&c. + M = 0,$$

an equation of (n) dimensions. Let its roots be determined, and let them be $\alpha, \beta, \gamma, \&c.$

Then the values of u_x will be $\alpha^x + A_1, \beta^x + A_1, \gamma^x + A_1, \&c.$, and $\alpha^x, \beta^x, \gamma^x, \&c.$ will be the (n) particular integrals of the equation

$$u_{x+n} + A u_{x+n-1} + B u_{x+n-2} + \&c. + M u_x = 0,$$

and $\therefore$ the complete integral of that equation will be

$$C' \alpha^x + C'' \beta^x + C''' \gamma^x + C'''' \delta^x + \&c.;$$

and $\therefore$ the complete integral of the original equation will be

$$C' \alpha^x + C'' \beta^x + C''' \gamma^x + \&c. + \frac{-N}{1 + A + B + \&c. + M}$$

Cor. (1.) If $N = 0, A_1 = 0$; and $\therefore u_x = a^x$ gives the solution of the equation

$$u_{x+n} + A u_{x+n-1} + B u_{x+n-2} + C u_{x+n-3} + \&c. + M u_x = 0.$$

Cor. (2.) If the equation $a^n + A a^{n-1} + B a^{n-2} + \&c. + M = 0$ contain equal roots, then the result would not, under its present form, have a sufficient number of arbitrary constants, and would not therefore be a complete solution.

Calculus of
Finite
Differences.

Calculus of
Finite
Differences.

Let us suppose that α and β are equal; and $\therefore C'\alpha^x + C''\beta^x = (C' + C'')\alpha^x$, which may be written $C_1\alpha^x$.
In such a case suppose for an instant that $\beta = (\alpha + \alpha_1)$;

$$\begin{aligned}\therefore C'\alpha^x + C''\beta^x &= C'\alpha^x + C''(\alpha + \alpha_1)^x \\ &= C'\alpha^x + C'' \left(\alpha^x + x \cdot \alpha^{x-1} \cdot \alpha_1 + \frac{x(x-1)}{2} \cdot \alpha^{x-2} \cdot \alpha_1^2 + \&c. \right) \\ &= (C' + C'')\alpha^x + \frac{C''\alpha_1}{\alpha} \cdot \alpha^x \cdot x + \frac{C'' \cdot \alpha^x \cdot x(x-1)}{\alpha^2} \alpha_1^2 + \&c. ;\end{aligned}$$

and putting $C' + C'' = C_1$, and $\frac{C''\alpha_1}{\alpha} = C_2$, and making $\alpha_1 = 0$;

$$\therefore C'\alpha^x + C''\beta^x = (C_1 + C_2x)\alpha^x.$$

And, similarly, if there be three roots, as α, β, γ equal, we must put instead of $C'\alpha^x + C''\beta^x + C'''\gamma^x$ the term $(C_1 + C_2x + C_3x^2)\alpha^x$; and similarly, in the cases where a greater number of roots are equal.

And if any of the roots be impossible, still the expression for u_x may be rendered possible by introducing, instead of the impossible quantities, the cosines and sines of the multiple arc. We shall, however, take an example which will illustrate this remark.

(121.) The general term of a recurring series, the scale of relation of which is given, may now be found. By the scale of relation is meant the constant coefficients which multiply a certain number of the preceding terms of a series, so that by addition of the terms so multiplied a required term may be found.

As a particular instance, let the scale of relation be $p - q + r$: find the general term.

Here

$$u_{x+3} = p \cdot u_{x+2} - q \cdot u_{x+1} + r \cdot u_x.$$

Let

$$u_x = a^x; \therefore u_{x+3} = a^{x+3};$$

$$\therefore a^{x+3} = p a^{x+2} - q a^{x+1} + r a^x;$$

$$\therefore a^3 - p a^2 + q a - r = 0, \text{ dividing by } a^x.$$

Let α, β, γ be the roots of this equation; $\therefore \alpha^x, \beta^x, \gamma^x$ are particular integrals of the original equation, and hence the complete integral is

$$u^x = C'\alpha^x + C''\beta^x + C'''\gamma^x.$$

(122.) It is obvious from the preceding article that if the scale of relation consisted of (n) terms, that the value of u_x would be expressed by the sum of (n) terms also, or that we may write it

$$u_x = C'\alpha^x + C''\beta^x + C'''\gamma^x + \&c. + C^n \nu^x.$$

This result indicates a remarkable circumstance which belongs to the nature of recurring series.

Here put instead of x the numbers 1, 2, 3, 4, &c., and we shall have the successive terms of the series, or u_1, u_2, u_3, u_4 , &c.; and if we express the series which is the sum of u_1, u_2, u_3 , &c., by Σ ,

$$\begin{aligned}\Sigma &= C'(\alpha + \alpha^2 + \alpha^3 + \&c. \dots \alpha^n) \\ &\quad + C''(\beta + \beta^2 + \beta^3 + \&c. + \beta^n) \\ &\quad + C'''(\gamma + \gamma^2 + \gamma^3 + \&c. + \gamma^n) \\ &\quad + \&c. ;\end{aligned}$$

and hence it appears that a recurring series, of which the scale of relation is $p - q + r + \&c.$, is composed of (n) geometric series, the ratios of which are the roots of the equation

$$a^n - p a^{n-1} + q a^{n-2} - r a^{n-3} + \&c. = 0.$$

It is to be observed that the roots are here supposed all possible and different.

Example (1.) Find the general term of the series when the scale of relation is $4 - 3$.

Here

$$u_{x+2} = 4 u_{x+1} - 3 u_x.$$

Make

$$u_x = a^x; \therefore a^2 = 4a - 3, \text{ dividing by } a^x;$$

$$\therefore a^2 - 4a + 3 = 0; \therefore a = 3 \text{ or } 1,$$

and

$$u_x = C' \cdot 3^x + C'' \cdot 1^x = C' 3^x + C''.$$

Example (2.) Let the scale of relation be $6 - 9$: find the general term.

Here

$$u_{x+2} = 6 u_{x+1} - 9 u_x;$$

and

$$\therefore a^2 - 6a + 9 = 0, \text{ or } (a - 3)^2 = 0; \therefore a = 3;$$

and, as two roots are equal, we must assume

$$u_x = (C_1 + C_2x) 3^x.$$

Example (3.) The scale of relation being $2 \cos \theta - 1$, find the general term of the series.

Here

$$u_{x+2} = 2 \cos \theta \cdot u_{x+1} - u_x;$$

$$\therefore \text{making } u_x = a^x, a^2 - 2 \cos \theta \cdot a = -1;$$

$$\therefore a^2 - 2 \cos \theta \cdot a + \cos^2 \theta = \cos^2 \theta - 1 = -\sin^2 \theta;$$

$$\therefore a = \cos \theta \pm \sqrt{-1} \sin \theta;$$

and the roots of the equation are

Calculus of
Finite
Differences.

Calculus of
Finite
Differences.

Calculus of
Finite
Differences

and $\therefore$ the particular integrals are

$$(\cos \theta + \sqrt{-1} \sin \theta)^x \text{ and } (\cos \theta - \sqrt{-1} \sin \theta)^x, \text{ or } \cos x\theta + \sqrt{-1} \sin x\theta \text{ and } \cos x\theta - \sqrt{-1} \sin x\theta;$$

and the complete integral is $\therefore$

$$\begin{aligned} u_x &= C' (\cos x\theta + \sqrt{-1} \sin x\theta) + C'' (\cos x\theta - \sqrt{-1} \sin x\theta) \\ &= (C' + C'') \cos x\theta + (C' - C'') \sqrt{-1} \sin x\theta \\ &= B (\sin A \cdot \cos x\theta + \cos A \cdot \sin x\theta) \\ &= B \sin (A + x\theta), \end{aligned}$$

by making

$$C' + C'' = B \sin A \text{ and } (C' - C'') \sqrt{-1} = B \cdot \cos A.$$

If the first term of the series be $\sin A$, then when

$$x = 0 \quad u_0 = \sin A = B \cdot \sin A; \therefore B = 1,$$

and

$$u_x = \sin (A + x\theta),$$

which result may be easily verified.

(123.) Next to integrate the equation $u_{x+2} - A_x \cdot u_{x+1} + B_x \cdot u_x = D_x$, we shall first show that it is integrable whenever $u_{x+2} - A_x u_{x+1} + B_x u_x = 0$ can be integrated.

Let
and

$$u_{x+1} - \alpha_x u_x = v_x, \quad (1)$$

$$v_{x+1} - \beta_x v_x = D_x; \quad (2)$$

$$\therefore u_{x+2} - \alpha_{x+1} u_{x+1} = v_{x+1} = \beta_x \cdot v_x + D_x = \beta_x u_{x+1} - \beta_x \alpha_x u_x + D_x,$$

or

$$u_{x+2} - (\alpha_{x+1} + \beta_x) u_{x+1} + \beta_x \alpha_x u_x = D_x;$$

which being of the same form as the original equation will be identical with it, if

$$\alpha_{x+1} + \beta_x = A_x, \text{ and if } \beta_x \alpha_x = B_x.$$

But the integration of the equations (1) and (2) gives

$$u_x = P \cdot \alpha_{x-1} \left(\sum \frac{v_x}{P \cdot \alpha_x} + C \right)$$

$$v_x = P \beta_{x-1} \left(\sum \frac{D_x}{P \cdot \beta_x} + C' \right);$$

and substituting for v_x , we have

$$\begin{aligned} u_x &= P \cdot \alpha_{x-1} \left(\sum \cdot \frac{P \cdot \beta_{x-1} \cdot \left(\sum \frac{D_x}{P \cdot \beta_x} + C' \right)}{P \cdot \alpha_x} + C \right) \\ &= C \cdot P \cdot \alpha_{x-1} + C' P \alpha_{x-1} \sum \cdot \frac{P \cdot \beta_{x-1}}{P \cdot \alpha_x} + P \cdot \alpha_{x-1} \sum \frac{P \cdot \beta_{x-1}}{P \cdot \alpha_x} \cdot \sum \frac{D_x}{P \cdot \beta_x} \\ &= C U_x + C' U'_x + Q_x \text{ by substitution.} \end{aligned}$$

Hence it appears that when α_x and β_x are known, the equation is integrable; the sole difficulty is therefore to determine these quantities.

Now from the equations $\alpha_{x+1} + \beta_x = A_x$ and $\beta_x \alpha_x = B_x$ it is plain that the values of α_x and β_x are independent of D_x ; and $\therefore$ are the same when $D_x = 0$. But then $u_x = C \cdot U_x + C' U'_x$, which is $\therefore$ the solution of the equation $u_{x+2} - A_x u_{x+1} + B_x u_x = 0$; and if this be integrable the functions, U_x and U'_x , which are its first integrals, will be known; and then α_x, β_x can be found, as we shall now show.

Since

$$U_x = P \cdot \alpha_{x-1}; \therefore U_{x+1} = P \cdot \alpha_x; \therefore \alpha_x = \frac{U_{x+1}}{U_x},$$

and

$$U'_x = P \cdot \alpha_{x-1} \sum \left(\frac{P \cdot \beta_{x-1}}{P \cdot \alpha_x} \right); \therefore U'_{x+1} = P \cdot \alpha_x \cdot \sum \left(\frac{P \cdot \beta_x}{P \cdot \alpha_{x+1}} \right);$$

$$\therefore \frac{U'_x}{U_x} = \sum \cdot \frac{P \cdot \beta_{x-1}}{P \cdot \alpha_x} \text{ and } \frac{U'_{x+1}}{U_{x+1}} = \sum \cdot \frac{P \cdot \beta_x}{P \cdot \alpha_{x+1}};$$

$$\therefore \Delta \left(\frac{U'_x}{U_x} \right) = \frac{P \cdot \beta_{x-1}}{P \cdot \alpha_x} \text{ and } \Delta \cdot \left(\frac{U'_{x+1}}{U_{x+1}} \right) = \frac{P \cdot \beta_x}{P \cdot \alpha_{x+1}};$$

whence

$$\therefore \frac{P \cdot \beta_x}{P \cdot \alpha_{x-1}} = \beta_x \text{ and } \frac{P \cdot \alpha_{x+1}}{P \cdot \alpha_x} = \alpha_{x+1} = \frac{U_{x+2}}{U_{x+1}};$$

$$\therefore \beta_x = \frac{U_{x+2}}{U_{x+1}} \cdot \frac{\Delta\left(\frac{U'_{x+1}}{U_{x+1}}\right)}{\Delta\left(\frac{U'_x}{U_x}\right)};$$

and thus α_x and β_x being found, the complete solution of the equation which is the subject of this article is found.
(124.) In a similar manner the integration of the equation

$$u_{x+3} - A_x u_{x+2} + B_x u_{x+1} - C_x u_x = D_x$$

may be shown to be dependent upon that of

$$u_{x+3} - A_x u_{x+2} + B_x u_{x+1} - C_x u_x = 0.$$

In this case we assume that

$$u_{x+1} - \alpha_x u_x = v_x \quad (1)$$

$$v_{x+1} - \beta_x v_x = w_x \quad (2)$$

$$w_{x+1} - \gamma_x w_x = D_x; \quad (3)$$

whence by eliminating v_x , v_{x+1} , w_x , and w_{x+1} we obtain

$$u_{x+3} - (\alpha_{x+2} + \beta_{x+1} + \gamma_x) u_{x+2} + (\alpha_{x+1} \cdot \beta_{x+1} + \alpha_{x+1} \gamma_x + \beta_x \cdot \gamma_x) u_{x+1} - \alpha_x \cdot \beta_x \cdot \gamma_x \cdot u_x = D_x,$$

which equation will coincide with the original one, if the three following equations be true, viz.

$$\alpha_{x+2} + \beta_{x+1} + \gamma_x = A_x, \quad \alpha_{x+1} \cdot \beta_{x+1} + \alpha_{x+1} \cdot \gamma_x + \beta_x \cdot \gamma_x = B_x,$$

and

$$\alpha_x \beta_x \gamma_x = C_x;$$

and integrating the equations (1), (2), (3), and proceeding as in the last article, we finally obtain

$$U_x = C U_x + C' U'_x + C'' U''_x + Q_x,$$

where

$$Q_x = P \cdot \alpha_{x-1} \Sigma \cdot \frac{P \beta_{x-1}}{P \cdot \alpha_x} \cdot \Sigma \frac{P \cdot \gamma_{x-1}}{P \cdot \beta_x} \cdot \Sigma \frac{D_x}{P \cdot \gamma_x}.$$

Now, as in the last article, the difficulty of integrating the equation will depend upon our finding the values of α_x , β_x , γ_x : but these quantities remain the same when $D_x = 0$, and $\therefore Q_x = 0$, and $\therefore$ when $u_x = C U_x + C' U'_x + C'' U''_x$. But this is the complete integral of $u_{x+3} - A_x u_{x+2} + B_x u_{x+1} - C_x u_x = 0$, and α_x , β_x , γ_x may be found when U_x , U'_x , and U''_x are given. Hence the truth of the proposition.

(125.) The difficulty of the process just detailed is much diminished when A_x , B_x , &c. are constant. As an example, let

$$u_{x+2} + A \cdot u_{x+1} + B \cdot u_x = D_x.$$

Here let
and

$$u_{x+1} - \alpha u_x = v_x \quad (1),$$

$$v_{x+1} - \beta v_x = D_x \quad (2);$$

whence

$$u_{x+2} - (\alpha + \beta) u_{x+1} + \alpha \beta \cdot u_x = D_x;$$

$$\therefore \alpha + \beta = A \text{ and } \alpha \beta = B:$$

i. e. α and β are the roots of $x^2 - A x + B = 0$.

But from (1)

$$u_x = \alpha^{x-1} \cdot \left(C + \Sigma \frac{v_x}{\alpha^x} \right);$$

from (2)

$$v_x = \beta^{x-1} \left(C' + \Sigma \frac{D_x}{\beta^x} \right);$$

$$\therefore u_x = C \alpha^{x-1} + \alpha^{x-1} \cdot \Sigma \cdot \frac{\beta^{x-1} \cdot \left(C' + \Sigma \frac{D_x}{\beta^x} \right)}{\alpha^x}$$

$$= \frac{C}{\alpha} \alpha^x + C' \frac{\alpha^x}{\beta \alpha} \cdot \Sigma \left(\frac{\beta}{\alpha} \right)^{x-1} + \frac{\alpha^x}{\alpha \beta} \cdot \Sigma \left(\frac{\beta}{\alpha} \right)^x \cdot \Sigma \frac{D_x}{\beta^x}$$

$$= C_1 \alpha^x + C_2 \beta^x + \frac{\alpha^x}{B} \Sigma \left(\frac{\beta}{\alpha} \right)^x \cdot \Sigma \cdot \frac{D_x}{\beta^x}.$$

For

$$\Sigma \left(\frac{\beta}{\alpha} \right)^{x-1} = \frac{\alpha}{\beta} \Sigma \left(\frac{\beta}{\alpha} \right)^x = \frac{\alpha}{\beta} \cdot \frac{\left(\frac{\beta}{\alpha} \right)^x}{\frac{\beta}{\alpha} - 1};$$

$$\therefore \frac{C' \alpha^x}{\beta \alpha} \cdot \Sigma \left(\frac{\beta}{\alpha} \right)^{x-1} = \frac{C' \alpha^x}{\beta \alpha} \cdot \frac{\alpha^2}{\beta} \cdot \left(\frac{\beta}{\alpha} \right)^x \cdot \frac{1}{\beta - \alpha} = \frac{C'}{\beta^2 \cdot (\beta - \alpha)} \beta^x = C_2 \beta^x.$$

Calculus of
Finite
Differences.

(126.) The preceding articles lead us to the general proposition, that the integration of the equation

$$u_{x+n} + P_x \cdot u_{x+n-1} + Q_x \cdot u_{x+n-2} + \&c. + U_x \cdot u_x = V_x \quad (1)$$

may be shown to be always dependent upon that of

$$u_{x+n} + P_x u_{x+n-1} + Q_x u_{x+n-2} + \&c. + U_x \cdot u_x = 0 \quad (2).$$

The following proof of this proposition was given by Lagrange, and from its simplicity, as well as the close analogy it bears to the proof of the similar problem in the Differential Calculus, it merits a place here.

 Suppose we have obtained (n) particular integrals of the equation (2), and let these be

$$u'_x, u''_x, u'''_x, \&c.;$$

then the complete integral of the equation (2) will be

$$u_x = C' u'_x + C'' u''_x + C''' u'''_x + \&c.$$

 But if, instead of supposing $C', C'', C''', \&c.$ to be (n) constant quantities, we assume them to be functions of x represented by $C'_x, C''_x, C'''_x, \&c.$ we may then assume

$$u_x = C'_x u'_x + C''_x u''_x + C'''_x u'''_x + \&c.$$

to be the complete solution of equation (1).

 Now writing $x+1$ for x we have

$$\begin{aligned} u_{x+1} &= C'_{x+1} \cdot u'_{x+1} + C''_{x+1} \cdot u''_{x+1} + C'''_{x+1} u'''_{x+1} + \&c. \\ &= C'_x u'_{x+1} + C''_x \cdot u''_{x+1} + C'''_x u'''_{x+1} + \&c. \\ &\quad + u'_{x+1} \Delta C'_x + u''_{x+1} \cdot \Delta C''_x + u'''_{x+1} \cdot \Delta C'''_x + \&c., \end{aligned}$$

by putting

Now make

and we have

whence

$$C'_x + \Delta C'_x, C''_x + \Delta C''_x, \&c. \text{ for } C'_{x+1}, C''_{x+1}, \&c.$$

$$u'_{x+1} \cdot \Delta C'_x + u''_{x+1} \cdot \Delta C''_x + u'''_{x+1} \cdot \Delta C'''_x + \&c. = 0,$$

$$u_{x+1} = C'_x u'_{x+1} + C''_x u''_{x+1} + C'''_x \cdot u'''_{x+1} + \&c.;$$

$$\begin{aligned} u_{x+2} &= C'_{x+1} u'_{x+2} + C''_{x+1} \cdot u''_{x+2} + C'''_{x+1} \cdot u'''_{x+2} + \&c. \\ &= C'_x u'_{x+2} + C''_x u''_{x+2} + C'''_x u'''_{x+2} + \&c. \\ &\quad + u'_{x+2} \cdot \Delta C'_x + u''_{x+2} \cdot \Delta C''_x + u'''_{x+2} \cdot \Delta C'''_x + \&c. \\ &= C'_x u'_{x+2} + C''_x \cdot u''_{x+2} + C'''_x \cdot u'''_{x+2} + \&c., \end{aligned}$$

by making

$$u'_{x+2} \cdot \Delta C'_x + u''_{x+2} \cdot \Delta C''_x + u'''_{x+2} \cdot \Delta C'''_x + \&c. = 0;$$

and thus proceeding, we shall at length have

and

$$u_{x+n-1} = C'_x u'_{x+n-1} + C''_x \cdot u''_{x+n-1} + C'''_x u'''_{x+n-1} + \&c.,$$

$$u'_{x+n-1} \Delta C'_x + u''_{x+n-1} \cdot \Delta C''_x + u'''_{x+n-1} \cdot \Delta C'''_x + \&c. = 0;$$

 and putting x instead of $x-1$ in u_{x+n-1} we finally have

$$\begin{aligned} u_{x+n} &= C'_x u'_{x+n} + C''_x u''_{x+n} + C'''_x u'''_{x+n} + \&c. \\ &\quad + u'_{x+n} \cdot \Delta C'_x + u''_{x+n} \cdot \Delta C''_x + u'''_{x+n} \cdot \Delta C'''_x + \&c.; \end{aligned}$$

 and substituting in equation (1) these values instead of $u_x, u_{x+1},$ and $u_{x+n},$ and bearing in mind that

$$u'_{x+n} + P_x u'_{x+n-1} + Q_x u'_{x+n-2} + \&c. + U_x u'_x = 0$$

$$u''_{x+n} + P_x u''_{x+n-1} + Q_x u''_{x+n-2} + \&c. + U_x u''_x = 0$$

$$\&c.;$$

 and observing that the first line is the coefficient of C'_x , the second of C''_x , $\&c.$, the equation will be reduced to

$$u'_{x+n} \cdot \Delta C'_x + u''_{x+n} \Delta C''_x + u'''_{x+n} \cdot \Delta C'''_x + \&c. = V_x;$$

 and from this and the other $n-1$ equations which involve $\Delta C'_x, \Delta C''_x, \Delta C'''_x, \&c.$, each of these differences may be found in terms of x , and their integration will be that of a single variable only; and thus $C'_x, C''_x, C'''_x, \&c.$ being found, the complete integral of (1) will be determined.

 (127.) The integration of the equation (2) can, however, be seldom effected when there is not some given or obvious relation between the coefficients: it is, however, as we have seen, readily integrated when the coefficients are constant, by the substitution of a^x for the unknown function u_x , and then we can integrate equation (1).

Thus, let the equation to be integrated be

$$u_{x+2} + A u_{x+1} + B u_x = D_x \quad (1);$$

 then the solution of $u_{x+2} + A u_{x+1} + B u_x = 0$ is $u_x = C' \alpha^x + C'' \beta^x$, where α and β are the roots of the equation $u^2 + A u + B = 0$.

 Now putting C'_x and C''_x for C' and C'' , we may assume $u_x = C'_x \alpha^x + C''_x \beta^x$ to be the solution of (1);

 Calculus of
Finite
Differences.

Calculus of
Finite
Differences.

$$\begin{aligned}\therefore u_{x+1} &= C'_{x+1} \alpha^{x+1} + C''_{x+1} \cdot \beta^{x+1} \\ &= C'_x \cdot \alpha^{x+1} + C''_x \beta^{x+1} + \alpha^{x+1} \Delta C'_x + \beta^{x+1} \cdot \Delta \cdot C''_x \\ &= C'_x \alpha^{x+1} + C''_x \beta^{x+1},\end{aligned}$$

Calculus of
Finite
Differences.

by making

$$\alpha^{x+1} \Delta C'_x + \beta^{x+1} \cdot \Delta \cdot C''_x = 0;$$

and

$$\therefore u_{x+2} = C'_x \alpha^{x+2} + C''_x \beta^{x+2} + \alpha^{x+2} \Delta C'_x + \beta^{x+2} \cdot \Delta C''_x$$

whence, by substituting in (1) for u_x , u_{x+1} , and u_{x+2} , we have

$$\alpha^{x+2} \cdot \Delta C'_x + \beta^{x+2} \cdot \Delta C''_x = D_x.$$

Also

$$\alpha^{x+1} \beta \cdot \Delta C'_x + \beta^{x+2} \cdot \Delta C''_x = 0;$$

$$\therefore \Delta C'_x = \frac{D_x}{(\alpha - \beta) \cdot \alpha^{x+1}}; \therefore C'_x = \frac{1}{\alpha - \beta} \cdot \Sigma \left(\frac{D_x}{\alpha^{x+1}} \right) + C_1,$$

and

$$\Delta \cdot C''_x = - \frac{D_x}{(\alpha - \beta) \beta^{x+1}}; \therefore C''_x = - \frac{1}{\alpha - \beta} \Sigma \frac{D_x}{\beta^{x+1}} + C_2;$$

$$\therefore u_x = C_1 \alpha^x + C_2 \beta^x + \frac{\alpha^x}{\alpha - \beta} \Sigma \frac{D_x}{\alpha^{x+1}} - \frac{\beta^x}{\alpha - \beta} \cdot \Sigma \frac{D_x}{\beta^{x+1}}.$$

(128.) The integration of the general equation of differences of the n th order, when the coefficients are functions of x , can seldom be effected.

In the simple case where $u_{x+1} = P_x u_x + Q_x$, we have already shown how the unknown function may be found. Laplace has given a very elegant process by which the equation may be solved; but as it leads only to the same result as we have already obtained, we pass by it and proceed to explain his method of reducing the equation to the one of lower degree.

Let
be the equation.

$$u_{x+n} = P_x u_{x+n-1} + Q_x u_{x+n-2} + \&c. + T_x u_{x+1} + U_x u_x + V_x$$

Suppose

$$\begin{aligned}u_{x+1} &= p_x u_x + q_x; \\ \therefore u_{x+2} &= p_{x+1} \cdot u_{x+1} + q_{x+1} \\ u_{x+3} &= p_{x+2} u_{x+2} + q_{x+2} \\ &\vdots \\ u_{x+n-1} &= p_{x+n-2} u_{x+n-2} + q_{x+n-2} \\ u_{x+n} &= p_{x+n-1} \cdot u_{x+n-1} + q_{x+n-1}.\end{aligned}$$

Multiply the first $n-1$ equations successively by the $n-1$ quantities $\alpha_1, \alpha_2, \alpha_3 \dots \alpha_{n-1}$, and then add the products to the n th equation, and we shall obtain

$$\begin{aligned}u_{x+n} &= (p_{x+n-1} - \alpha_{n-1}) u_{x+n-1} + (\alpha_{n-1} \cdot p_{x+n-2} - \alpha_{n-2}) u_{x+n-2} \\ &\quad + (\alpha_{n-2} p_{x+n-3} - \alpha_{n-3}) u_{x+n-3} + \&c. + \alpha_1 p_x \cdot u_x \\ &\quad + q_{x+n-1} + \alpha_{n-1} \cdot q_{x+n-2} + \alpha_{n-2} \cdot q_{x+n-3} + \&c. + \alpha_1 q_x.\end{aligned}$$

Comparing this with the original equation we have the following results, if the equations be supposed identical:

$$\begin{aligned}P_x &= p_{x+n-1} - \alpha_{n-1} \\ Q_x &= \alpha_{n-1} \cdot p_{x+n-2} - \alpha_{n-2} \\ R_x &= \alpha_{n-2} \cdot p_{x+n-3} - \alpha_{n-3} \\ &\vdots \\ T_x &= \alpha_2 \cdot p_{x+1} - \alpha_1 \\ U_x &= \alpha_1 p_x \\ V_x &= q_{x+n-1} + \alpha_{n-1} \cdot q_{x+n-2} + \alpha_{n-2} \cdot q_{x+n-3} + \&c. + \alpha_1 q_x;\end{aligned}$$

whence we have

$$\begin{aligned}\alpha_{n-1} &= p_{x+n-1} - P_x \\ \alpha_{n-2} &= p_{x+n-1} \cdot p_{x+n-2} - p_{x+n-2} \cdot P_x - Q_x \\ \alpha_{n-3} &= p_{x+n-1} p_{x+n-2} \cdot p_{x+n-3} - p_{x+n-2} \cdot p_{x+n-3} \cdot P_x - p_{x+n-3} Q_x - R_x \\ &\vdots \\ \alpha_1 &= [p_{x+n-1}]^{n-1} - [p_{x+n-2}]^{n-2} \cdot P_x - [p_{x+n-3}]^{n-3} \cdot Q_x - \&c. - T_x;\end{aligned}$$

and

$$\therefore U_x = \alpha_1 p_x = [p_{x+n-1}]^n - [p_{x+n-2}]^{n-1} P_x - [p_{x+n-3}]^{n-2} Q_x - \&c. - T_x p_x;$$

an equation which is of the order $n-1$, since it contains only the values $p_x, p_{x+1} \dots p_{x+n-1}$ but which is not of the first degree. Suppose this to be solved, or that we know some value of p_x which will satisfy it, we shall then obtain the value $\alpha_1, \alpha_2, \alpha_3 \dots \alpha_{n-1}$; and let their values be substituted in the equation

$$V_x = q_{x+n-1} + \alpha_{n-1} \cdot q_{x+n-2} + \alpha_{n-2} \cdot q_{x+n-3} + \&c. + \alpha_1 q_x,$$

Calculus of
Finite
Differences.

which is of $n-1$ dimensions, and this being integrated we shall obtain q_x , and thus finally to find u_x we have to solve the equation $u_{x+1} = p_x u_x + q_x$, of which the solution is known to be

Calculus of
Finite
Differences.

$$u_x = [p_{x-1}]^x \left\{ C + \sum \frac{q_x}{[p_x]^{x+1}} \right\}.$$

(129.) Although this process is difficult of application, yet there are cases in which it may be used with complete success; and, as an illustration, we will take the particular example

$$u_{x+3} = A p^x u_{x+2} + B p^{2x} u_{x+1} + C p^{3x} u_x.$$

Here it is obvious that as $V_x = 0$ $q_x = 0$.

Let

$$\therefore u_{x+1} = v_x u_x; \quad (1)$$

$$\therefore u_{x+2} = v_{x+1} \cdot u_{x+1} \quad (2)$$

$$u_{x+3} = v_{x+2} u_{x+2}; \quad (3)$$

.. multiply (1) and (2) by $\alpha_1 \alpha_2$ respectively, and adding their products to (3),

$$\begin{aligned} u_{x+3} &= (v_{x+2} - \alpha_2) u_{x+2} + (\alpha_2 v_{x+1} - \alpha_1) u_{x+1} + \alpha_1 v_x u_x; \\ \therefore v_{x+2} - \alpha_2 &= A \cdot p^x, \quad \alpha_2 v_{x+1} - \alpha_1 = B p^{2x}, \quad \alpha_1 v_x = C \cdot p^{3x}; \\ \therefore \alpha_2 &= v_{x+2} - A p^x \\ \alpha_1 &= v_{x+2} \cdot v_{x+1} - A \cdot v_{x+1} \cdot p^x - B p^{2x}, \end{aligned}$$

and

$$v_{x+2} \cdot v_{x+1} v_x - A v_{x+1} \cdot v_x \cdot p^x - B v_x p^{2x} - C p^{3x} = 0. \quad (4)$$

The difficulty is to solve this equation.

Now make

$$v_x = m \cdot p^{x+1};$$

$$\therefore v_{x+1} = m p^{x+2} \text{ and } v_{x+2} = m p^{x+3}.$$

Substituting these values in equation (4) we have

$$m^3 p^{3x+6} - A m^2 \cdot p^{3x+3} - B m \cdot p^{3x+1} - C \cdot p^{3x} = 0,$$

or

$$m^3 - \frac{A m^2}{p^3} - \frac{B \cdot m}{p^5} - \frac{C}{p^6} = 0$$

a cubic equation, of which let the roots be a, b, c . Then the values of v_x are $a p^{x+1}, b p^{x+1}, c p^{x+1}$.

Let

To integrate which let

$$v_x = a p^{x+1}; \therefore u_{x+1} = a p^{x+1} u_x.$$

$$u_x = a^{x-1} \cdot (p^1 p^2 \cdot p^3 \dots p^x) u'_x = a^{x-1} \cdot p^{\frac{x \cdot x+1}{2}} u'_x$$

$$\therefore u_{x+1} = a^x \cdot p^{\frac{x+1 \cdot x+2}{2}} u'_{x+1} = \therefore a^x \cdot p^{\frac{x \cdot x+1}{2}} p^{x+1} \cdot u'_x = a^x p^{\frac{x+1 \cdot x+2}{2}} \cdot u'_x;$$

$$\therefore u'_{x+1} = u'_x; \therefore \Delta \cdot u'_x = 0; \therefore u'_x = \text{a constant} = C_1 \cdot a,$$

and

$$\therefore u_x = C_1 a^x \cdot p^{\frac{x \cdot x+1}{2}}.$$

This is only the first integral of u_x , the others are $C_1 b^x \cdot p^{\frac{x \cdot x+1}{2}}$, and $C_2 c^x \cdot p^{\frac{x \cdot x+1}{2}}$; and $\therefore$ the complete integral will be

$$u_x = p^{\frac{x \cdot x+1}{2}} \cdot \{C_1 a^x + C_2 b^x + C_3 c^x\};$$

and by the same process the general equation

$$u_{x+n} = A p^x u_{x+n-1} + B p^{2x} u_{x+n-2} + \&c. L p^{4x} u_x$$

may be solved; and if $a, b, c, \&c. l$ be the roots of the equation

$$m^n - \frac{A m^{n-1}}{p^n} - \frac{B m^{n-1}}{p^{2n-1}} - \frac{C m^{n-2}}{p^{3n-3}} - \&c. - \frac{L}{p^{\frac{n \cdot n+1}{2}}} = 0,$$

then we shall find, as before, that

$$u_x = p^{\frac{x \cdot x+1}{2}} \{C_1 a^x + C_2 b^x + C_3 c^x + \&c. + C l^x\}.$$

(130.) In a similar manner may be integrated the more general equation

$$u_{x+n} = A X_{x+m} \cdot u_{x+n-1} + B \cdot X_{x+m} \cdot X_{x+m-1} \cdot u_{x+n-2} + \&c. + L \cdot X_{x+m} \dots X_{x+m-n+1} u_x$$

where $A, B, C, \&c. L$ are constant quantities.

As in the preceding example, make $u_{x+1} = u_x p_x$, and then to determine p_x we shall have the equation

$$[p_{x+n-1}]^n - A \cdot X_{x+m} \cdot [p_{x+n-1}]^{n-1} - B [X_{x+m}]^2 \cdot [p_{x+n-2}]^{n-2} - \&c. - L [X_{x+m}]^n = 0.$$

Assume

$$p_x = a \cdot X_{x+m-n+1}; \therefore p_{x+1} = a \cdot X_{x+m-n+2} \&c.;$$

$$\therefore [p_{x+n-1}]^n = a^n \cdot [X_{x+m}]^n, \text{ and } [p_{x+n-2}]^{n-1} = a^{n-1} \cdot [X_{x+m-1}]^{n-1} \cdot \&c. = \&c.;$$

Calculus of
Finite
Differences.

and substituting these values, the whole equation will be divisible by $[X_{x+m}]^n$, and we have the equation of (n) dimensions,

Calculus of
Finite
Differences.

$$a^n - A a^{n-1} - B a^{n-2} - C a^{n-3} - \&c. - L = 0.$$

Let the roots of this equation be $\alpha, \beta, \gamma, \delta, \&c.$, then the values of p_x will be, if for simplicity we put $m = n - 1$,

$$\alpha X_x, \beta X_x, \gamma X_x, \delta X_x, \&c.;$$

and $\therefore$ the value of u_x will be found from the integration of the equation

$$u_{x+1} = \alpha X_x \cdot u_x,$$

whence

$$u_x = C_1 \alpha^x \cdot [X_{x-1}]^x,$$

which is one of the first integrals, and $\therefore$ the complete integral will be

$$u_x = [X_{x-1}]^x \cdot \{C_1 \alpha^x + C_2 \beta^x + C_3 \gamma^x + C_4 \delta^x + \&c.\}.$$

Cor. Let
and

$$X_x = p^{x+1}; \therefore X_{x-1} = p^x \text{ and } [X_{x-1}]^x = p^{\frac{x \cdot x+1}{2}},$$

$$u_x = p^{\frac{x \cdot x+1}{2}} \{C_1 \alpha^x + C_2 \beta^x + C_3 \gamma^x + \&c.\},$$

as in the preceding example.

Cor. Hence may be integrated the equation

$$u_{x+n} = A \cdot x \cdot u_{x+n-1} + B x \cdot \overline{x-1} u_{x+n-2} + C \cdot x \cdot \overline{x-1} \overline{x-2} u_{x+n-3} + \&c. \\ + L \cdot x \cdot \overline{x-1} \overline{x-2} \dots 1 \cdot U_x;$$

the integral of which is

$$u_x = (1 \cdot 2 \cdot 3 \dots x) \{C_1 \alpha^x + C_2 \beta^x + C_3 \gamma^x + \&c. + C_n \lambda^x\},$$

where $\alpha, \beta, \gamma, \&c. \lambda$ are the roots of the equation

$$a^n - A a^{n-1} - B a^{n-2} - C a^{n-3} - \&c. - L = 0.$$

(131.) Of equations higher than the first degree little is known, and when solved, their solution is effected by particular artifices.

The equation $u_{x+1} \cdot u_x - a u_{x+1} + b u_x + c = 0$ may be thus solved.

Let

$$u_x = \frac{v_{x+1}}{v_x} + k;$$

and then we have

$$\left(\frac{v_{x+2}}{v_{x+1}} + k\right) \cdot \left(\frac{v_{x+1}}{v_x} + k\right) - a \left(\frac{v_{x+2}}{v_{x+1}} + k\right) + b \left(\frac{v_{x+1}}{v_x} + k\right) + c = 0,$$

or

$$\frac{v_{x+2}}{v_x} + (k-a) \frac{v_{x+2}}{v_{x+1}} + (k+b) \frac{v_{x+1}}{v_x} + k^2 - a k + b k + c = 0.$$

Let $k - a = 0$, or $k = a$, and multiply by v_x ,

$$\therefore v_{x+2} + (a+b) v_{x+1} + (b a + c) v_x = 0;$$

the integral of which may be found by putting $v_x = m^x$; and if α and β be the roots of $m^2 + (a+b)m + b a + c = 0$, the complete integral will be $v_x = p \alpha^x + q \beta^x$, where p and q are constant quantities;

$$\therefore u_x = \frac{v_{x+1}}{v_x} + k = \frac{p \alpha^{x+1} + q \beta^{x+1}}{p \alpha^x + q \beta^x} + \alpha \\ = \frac{\alpha^{x+1} + C \beta^{x+1}}{\alpha^x + C \beta^x} + k, \text{ if } C = \frac{p}{q}.$$

(132.) The following example may be solved by a particular artifice.

Example. Let

$$u_{x+2} \cdot u_{x+1} \cdot u_x = a (u_{x+2} + u_{x+1} + u_x);$$

then, since when

$$A + B + C = 0, \tan A \cdot \tan B \cdot \tan C = \tan A + \tan B + \tan C.$$

Let

$$u_x = \sqrt{a} \tan v_x; \therefore u_{x+1} = \sqrt{a} \cdot \tan v_{x+1}, \text{ and } u_{x+2} = \sqrt{a} \tan v_{x+2};$$

$$\therefore a^{\frac{3}{2}} (\tan v_{x+2} \cdot \tan v_{x+1} \cdot \tan v_x) = a^{\frac{3}{2}} (\tan v_{x+2} + \tan v_{x+1} + \tan v_x);$$

$$\therefore \tan v_{x+2} \cdot \tan v_{x+1} \cdot \tan v_x = \tan v_{x+2} + \tan v_{x+1} + \tan v_x;$$

$$\therefore v_{x+2} + v_{x+1} + v_x = 0.$$

$$x = b^x; \therefore b^2 + b + 1 = 0;$$

Make
whence

$$b = -\frac{1}{2} \pm \frac{\sqrt{-3}}{2} = -\frac{1}{2} \pm \sqrt{-1} \frac{\sqrt{3}}{2} = \cos \frac{2\pi}{3} \pm \sqrt{-1} \sin \frac{2\pi}{3};$$

$$\therefore b^x = \cos \frac{2\pi x}{3} \pm \sqrt{-1} \sin \frac{2\pi x}{3};$$

$$\therefore v_x = C' \left(\cos \frac{2\pi x}{3} + \sqrt{-1} \sin \frac{2\pi x}{3} \right) + C'' \left(\cos \frac{2\pi x}{3} - \sqrt{-1} \sin \frac{2\pi x}{3} \right) \\ = C_1 \cos \frac{2\pi x}{3} + C_2 \sin \frac{2\pi x}{3};$$

whence

$$C_1 = C' + C'' \text{ and } C_2 = (C' - C'')\sqrt{-1}; \\ \therefore u_x = \sqrt{a} \cdot \tan \left\{ C_1 \cos \frac{2\pi x}{3} + C_2 \sin \frac{2\pi x}{3} \right\}.$$

For this and similar examples, see Herschell's Examples on Finite Differences.
(133.) By a similar substitution may be integrated the equation

For

$$u_{x+1} - 2u_x^2 + 1 = 0, \text{ or } u_{x+1} = 2u_x^2 - 1.$$

whence

$$\therefore \cos 2A = 2\cos^2 A - 1, \therefore \text{let } u_x = \cos v_x;$$

whence

$$\therefore u_{x+1} = \cos v_{x+1}; \therefore \cos v_{x+1} = 2(\cos v_x)^2 - 1;$$

$$v_{x+1} = 2v_x; \therefore \text{if } v_x = a^x, \therefore a = 2 \text{ and } v_x = C \cdot 2^x;$$

$$u_x = \cos v_x = \cos (C \cdot 2^x) = \frac{1}{2} (e^{2^x \cdot C\sqrt{-1}} + e^{-2^x \cdot C\sqrt{-1}}) = \frac{1}{2} (C_1^{2^x} + C_1^{-2^x}).$$

(134.) The equation $u_x = V_x \cdot u_{x-1}^{\alpha} \cdot u_{x-2}^{\beta} \cdot u_{x-3}^{\gamma} \dots u_{x-n}^{\nu}$, which expresses that the general term of a series is a function of the product of the preceding terms, may be easily referred to the solution of an equation of the n th order.

Taking the logarithm of each side of the equation,

$$\log u_x = \log V_x + \alpha \log u_{x-1} + \beta \log u_{x-2} + \gamma \log u_{x-3} + \&c. + \nu \log u_{x-n};$$

for $\log V_x$ put U_x , and for $\log u_x$ write v_x ;

$$\therefore v_x = U_x + \alpha v_{x-1} + \beta v_{x-2} + \gamma v_{x-3} + \&c. + \nu v_{x-n}.$$

If U_x be constant, this equation is easily integrable by making

$$v_{x-n} = a^x, \text{ and } \therefore v_x = a^{x+n}.$$

(135.) Equations of mixed differences, when the coefficients are constants, admit of integration by substituting $e^{kx} + H$ for u_x . As an example, we will take the following equation,

$$u_x + A u_{x+1} + B \cdot \frac{d \cdot u_x}{dx} + C \cdot \frac{d \cdot u_{x+1}}{dx} + k = 0;$$

$$\therefore e^{kx} + H + A e^{k(x+1)} + A H + B k e^{kx} + C k e^{k(x+1)} + k = 0.$$

Make

$$H + A H + k = 0, \text{ or } H = \frac{-k}{1+A};$$

$$\therefore e^{kx} + A e^{k(x+1)} + B k e^{kx} + C k e^{k(x+1)} = 0$$

$$1 + A e^k + B k + C k e^k = 0.$$

Let $k_1, k_2, k_3, \&c.$ be the values of k found from this equation, then will

$$v_x = C_1 e^{k_1 x} + C_2 e^{k_2 x} + C_3 e^{k_3 x} + \&c. - \frac{k}{1+A}$$

$$= C_1 \alpha^x + C_2 \beta^x + C_3 \gamma^x + \&c. - \frac{k}{1+A},$$

by making the proper substitutions.

(136.) Want of space alone prevents any mention of those equations of differences which involve more than one variable; the reader is referred to the great work of Lacroix, and to various Papers by Laplace, as well as that invaluable collection of Examples of Sir John Herschell, the almost constant subject of our reference. We shall conclude this portion of our Treatise by an application of the theory of continued fractions to equations of finite differences.

(137.) In the *Mécanique Céleste*, vol. iv., p. 254, Laplace has shown that every linear equation of the second order of finite differences may be reduced to a continued fraction. The following is the method used by him.

Let the equation be expressed by

$$u_x = a_x u_{x+1} + b_x u_{x+2};$$

$$\therefore \frac{u_x}{u_{x+1}} = a_x + b_x \cdot \frac{u_{x+2}}{u_{x+1}};$$

and

$$\therefore \frac{u_{x+1}}{u_x} = \frac{1}{a_x + b_x \cdot \frac{u_{x+2}}{u_{x+1}}};$$

Calculus of
Finite
Differences.

and

Calculus of
Finite
Differences.

$$\frac{u_{x+2}}{u_{x+1}} = \frac{1}{a_{x+1} + b_{x+1} \cdot \frac{u_{x+3}}{u_{x+2}}},$$

$$\frac{u_{x+3}}{u_{x+2}} = \frac{1}{a_{x+2} + b_{x+2} \cdot \frac{u_{x+4}}{u_{x+3}}}, \text{ \&c. ;}$$

and thus substituting we can form the continued fraction

$$\frac{u_{x+1}}{u_x} = \frac{1}{a_x + \frac{b_x}{a_{x+1} + \frac{b_{x+1}}{a_{x+2} + \text{\&c.}}}}$$

And making $a_x = 1$, $b_x = (x+1)q$, or $u_x = u_{x+1} + x+1 \cdot q u_{x+2}$, then

$$\frac{u_{x+1}}{u_x} = \frac{1}{1 + \frac{x+1 \cdot q}{1 + \frac{x+2 \cdot q}{1 + \frac{x+3 \cdot q}{1 + \text{\&c.}}}}}$$

And, finally, making $x = 0$,

$$\frac{u_1}{u_0} = \frac{1}{1 + \frac{2q}{1 + \frac{3q}{1 + \frac{4q}{1 + \text{\&c.}}}}}$$

fractions which express in an elegant manner the relations which exist between two successive terms of a series.

(138.) And, conversely, we may show how the value of a continued fraction can be found by means of an equation of finite differences.

Thus, let $\frac{U}{V}$ be the true value of the fraction

$$= \frac{c}{a + \frac{c}{a + \frac{c}{a + \text{\&c.}}}}$$

and let

$$\frac{u_1}{v_1}, \frac{u_2}{v_2}, \frac{u_3}{v_3} \dots \frac{u_x}{v_x}$$

represent the successive convergent fractions; then it is shown (see ALGEBRA, art. 234.) that

$$u_{x+2} = a u_{x+1} + c u_x,$$

and

$$v_{x+2} = a v_{x+1} + c v_x;$$

whence, by integration,

$$u_x = C_1 \alpha^x + C_2 \beta^x,$$

and

$$v_x = C' \alpha^x + C'' \beta^x,$$

where α and β are the roots of $u^2 = a u + c$;

$$\therefore \frac{u_x}{v_x} = \frac{C_1 \alpha^x + C_2 \beta^x}{C' \alpha^x + C'' \beta^x} = \frac{C_1 + C_2 \left(\frac{\beta}{\alpha}\right)^x}{C' + C'' \left(\frac{\beta}{\alpha}\right)^x},$$

where (α) is supposed to be the greater of the roots α, β ; whence, if F_∞ be the value of the fraction continued to infinity,

$$F_\infty = \frac{C_1}{C'}.$$

(139.) To find the constants C_1, C_2, C', C'' , we have, since

$$\begin{aligned} u_1 &= c, u_2 = c a, \text{ and } v_1 = a \text{ and } v_2 = a^2 + c; \\ \therefore c &= C_1 \alpha + C_2 \beta & a &= C' \alpha + C'' \beta \\ c a &= C_1 \alpha^2 + C_2 \beta^2 & a^2 + c &= C' \alpha^2 + C'' \beta^2; \end{aligned}$$

Calculus of whence
Finite
Differences.

but

$$C_1 = c \frac{a - \beta}{\alpha^2 - \beta \alpha} = \text{and } C' = \frac{a^2 + c - a\beta}{\alpha^2 - \beta \alpha},$$

$$\alpha + \beta = a \text{ and } c = -\alpha\beta; \therefore a - \beta = \alpha \text{ and } a^2 - a\beta = a\alpha;$$

$$\therefore C_1 = \frac{c}{\alpha - \beta}; \therefore C' = \frac{c + a\alpha}{\alpha^2 - \beta \alpha} = \frac{a - \beta}{\alpha - \beta} = \frac{\alpha}{\alpha - \beta};$$

and

$$C_2 \beta = c - C_1 \alpha = c - \frac{c\alpha}{\alpha - \beta} = \frac{-c\beta}{\alpha - \beta}; \therefore C_2 = \frac{-c}{\alpha - \beta} = -C_1$$

$$C'' \beta = a - C' \alpha = a - \frac{\alpha^2}{\alpha - \beta} = \frac{a\alpha - a\beta - \alpha^2}{\alpha - \beta} = \frac{\alpha\beta - a\beta}{\alpha - \beta} = \frac{-\beta^2}{\alpha - \beta};$$

$$\therefore C'' = \frac{-\beta}{\alpha - \beta} = \frac{-\beta}{\alpha} C';$$

$$\therefore \frac{u_x}{v_x} = \frac{C_1 (\alpha^x - \beta^x)}{C' \left(\alpha^x - \frac{\beta}{\alpha} \beta^x \right)} = \frac{c \cdot (\alpha^x - \beta^x)}{\alpha^{x+1} - \beta^{x+1}},$$

a formula of singular neatness.

If we divide each term by α^x , and make $x = \alpha^y$, then, since $\frac{\beta}{\alpha}$ is a proper fraction,

$$F_\infty = \frac{C_1}{C'} = \frac{c}{\alpha}.$$

Example (1.) Find the value of the fraction $\frac{1}{1 + \frac{1}{1 + \frac{1}{1 + \&c.}}}$ to infinity.

Here
whence

$$\alpha = 1, c = 1; \therefore u^2 - u = 1;$$

$$\alpha = \frac{\sqrt{5} + 1}{2};$$

$$\therefore F_\infty = \frac{c}{\alpha} = \frac{2}{\sqrt{5} + 1} = \frac{\sqrt{5} - 1}{2}.$$

Example (2.) Find the value of $\frac{2}{1 + \frac{2}{1 + \frac{2}{1 + \&c.}}}$ to x terms.

Here

$$c = 2, a = 1, u^2 - u = 2; \therefore \alpha = 2 \text{ and } \beta = -1;$$

$$\therefore \frac{u_x}{v_x} = \frac{2 \cdot (2^x - (-1)^x)}{2^{x+1} - (-1)^{x+1}} = \frac{2^{x+1} - 2(-1)^x}{2^{x+1} - (-1)^{x+1}}.$$

The Theory of Generating Functions.

(140.) Let u_x be any function whatever of x ; and let us suppose $\phi(t)$ to be such a function of t , that its developement according to the powers of t shall produce the series

$$\dots + u_{-1} t^{-1} + u_0 + u_1 t + u_2 t^2 + u_3 t^3 + \&c. + u_{x-1} t^{x-1} + u_x \cdot t^x + u_{x+1} \cdot t^{x+1} + \&c.;$$

then $\phi(t)$ is said to be the *generating function* of u_x .

In this expansion we observe that u_x is the coefficient of t^x ; and, in general, the *generating function* of any variable whatever, as u_x , is defined to be such a function of t as, when expanded according to the powers of t , shall have this variable for the coefficient of t^x ; and, conversely, the variable corresponding to a *generating function* is the coefficient of t^x in the expansion of the function according to the powers of t .

It must be observed that the series for $\phi(t)$ is supposed to extend both ways, and thus include negative as well as positive powers of t .

(141.) As examples of these generating functions. Since

$$\frac{t}{(1-t)^2} = 1t + 2t^2 + 3t^3 + 4 \cdot t^4 + \&c. + xt^x + \overline{x+1} t^{x+1} + \&c.,$$

and

Calculus of
Finite
Differences.

Calculus of
Finite
Differences.

$$\log \frac{1}{(1-t)} = \frac{t}{1} + \frac{t^2}{2} + \frac{t^3}{3} + \frac{t^4}{4} + \&c. + \frac{t^x}{x} + \frac{t^{x+1}}{x+1} + \&c.;$$

Calculus of
Finite
Differences.

then $\frac{t}{(1-t)^2}$ and $\log \frac{1}{(1-t)}$ are respectively the generating functions of x and $\frac{1}{x}$. For x and $\frac{1}{x}$ are the coefficients of t^x in their respective series.

(142.) Resuming the expansion for $\phi(t)$, we have

$$\phi(t) = \dots + u_0 + u_1 t + u_2 t^2 + u_3 t^3 + \&c. \dots + u_{x-1} t^{x-1} + u_x t^x + u_{x+1} t^{x+1} + \&c.;$$

$$\therefore t \phi(t) = u_0 t + u_1 t^2 + u_2 t^3 + \&c. \dots + u_{x-1} t^x + u_x t^{x+1} + \&c.;$$

in which series, as u_{x-1} is the coefficient of t^x , therefore $t \phi(t)$ is the generating function of u_{x-1} . Again, multiplying by t , we shall have u_{x-2} for the coefficient of t^x in the expansion of $t^2 \phi(t)$; hence $t^2 \phi(t)$ is the generating function of u_{x-2} ; and thus, finally, $t^n \phi(t)$ will be the generating function of u_{x-n} .

Again, if we divide $\phi(t)$ by t , we shall have

$$\frac{1}{t} \phi(t) = \dots + u_1 + u_2 t + u_3 t^2 + \&c. + u_x t^{x-1} + u_{x+1} t^x + u_{x+2} t^{x+1} + \&c.;$$

or $\frac{1}{t} \phi(t)$ is the generating function of u_{x+1} .

Similarly $\frac{1}{t^2} \phi(t)$ is the generating function of u_{x+2} , and $\frac{1}{t^n} \phi(t)$ that of u_{x+n} .

Whence it appears that if we know the generating function of u_x we can immediately obtain those of u_{x-n} or of u_{x+n} by multiplying or dividing by t^n .

(143.) If we take the difference between the expansions of $\frac{1}{t} \phi(t)$ and $\phi(t)$, the coefficient of t^x will be $u_{x+1} - u_x$ or Δu_x , therefore the generating function of Δu_x is $\left(\frac{1}{t} - 1\right) \phi(t)$. Let this be written $\phi'(t)$, then the generating function of $\Delta u_{x+1} - \Delta u_x$ or $\Delta^2 u_x$ will be $\left(\frac{1}{t} - 1\right) \phi' t = \left(\frac{1}{t} - 1\right)^2 \phi t$.

Similarly, the generating function of $\Delta^3 u_x$ is $\left(\frac{1}{t} - 1\right)^3 \phi(t)$, and that of $\Delta^n u_x$ is $\left(\frac{1}{t} - 1\right)^n \phi(t)$.

(144.) We have hitherto considered Δu_x to be equal to $u_{x+1} - u_x$; it might, however, be supposed to be any combination of the quantities $u_x, u_{x+1}, u_{x+2}, \&c.$; suppose it to be $a u_x + b u_{x+1} + c u_{x+2} + \&c. + q u_{x+n}$, and call this quantity ∇u_x .

Then since the coefficient of t^x in the development of

$$\phi(t) \left\{ a + \frac{b}{t} + \frac{c}{t^2} + \frac{e}{t^3} + \&c. + \frac{q}{t^n} \right\}$$

is

$$a u_x + b u_{x+1} + c u_{x+2} + e u_{x+3} + \&c. + q u_{x+n};$$

$$\therefore \phi(t) \left\{ a + \frac{b}{t} + \frac{c}{t^2} + \frac{e}{t^3} + \&c. + \frac{q}{t^n} \right\}$$

is the generating function of ∇u_x ; and if, as before, we call this function $\phi'(t)$, and if $\nabla^2 u_x$ be what ∇u_x becomes when ∇u_x is written for u_x , then

$$\phi'(t) \left(a + \frac{b}{t} + \frac{c}{t^2} + \&c. + \frac{q}{t^n} \right) \text{ or } \phi(t) \left\{ a + \frac{b}{t} + \frac{c}{t^2} + \&c. + \frac{q}{t^n} \right\}^2$$

will be the generating function of $\nabla^2 u_x$; and, in general, the generating function of $\nabla^m u_x$ is

$$\phi(t) \left\{ a + \frac{b}{t} + \frac{c}{t^2} + \frac{e}{t^3} + \&c. + \frac{q}{t^n} \right\}^m.$$

(145.) To extend the reasoning to integrals, let z be the generating function of $\Sigma^n u_x$; then, from what has preceded, $\left(\frac{1}{t} - 1\right)^n z$ will be the generating function of $\Delta^n (\Sigma^n u_x)$ or of u_x ; but as $\phi(t)$ is the generating function of u_x we may put

$$z \cdot \left(\frac{1}{t} - 1\right)^n = \phi(t), \text{ and } \therefore z = \phi(t) \cdot \left(\frac{1}{t} - 1\right)^{-n};$$

whence it appears that we can obtain the generating function of $\Sigma^n u_x$ from that of $\Delta^n u_x$, by merely changing (n) into $(-n)$. We have here neglected the constants and the powers of x which are introduced into the value of the integral by each successive integration; but to make the generating function complete we must assume

$$z = \phi(t) \left(\frac{1}{t} - 1\right)^{-n} + \frac{A_1}{(1-t)^n} + \frac{A_2 t}{(1-t)^n} + \frac{A_3 t^2}{(1-t)^n} + \&c. + \frac{A_n \cdot t^{n-1}}{(1-t)^n};$$

Calculus of Finite Differences. for these fractions being expanded, the coefficients of t^x in the expanded series will give the (n) constants and the powers of x , which are requisite to complete the integral. Calculus of Finite Differences. As an example, let $n = 1$. Then the integration of $\sum u_x$ will introduce but one constant, and we have

$$z = \phi(t) \left(\frac{1}{t} - 1 \right)^{-1} + \frac{A}{1-t}.$$

But the coefficient of t^x in $\frac{A}{1-t}$ is only A , and

$$\therefore \sum(u_x) = f(x) + A.$$

Again, let $n = 2$;

$$\therefore z = \phi(t) \left(\frac{1}{t} - 1 \right)^{-2} + \frac{A_1}{(1-t)^2} + \frac{A_2 t}{(1-t)^2}.$$

But the coefficients of t^x in $\frac{1}{(1-t)^2}$ and $\frac{t}{(1-t)^2}$ are $x+1$ and x ;

$$\therefore \sum^2 u_x = \sum f(x) + (A_1 + A_2)x + A_1 = \sum f(x) + Bx + A_1.$$

(146.) We shall now show the use of the calculus of generating functions, in proving some of the theorems demonstrated in the preceding pages.

The generating function of $\Delta^n u_x$ being $\left(\frac{1}{t} - 1 \right)^n \phi(t)$, expand $\left(\frac{1}{t} - 1 \right)^n$, and multiply each term by $\phi(t)$, and we have

$$\frac{1}{t^n} \phi(t) - n \frac{1}{t^{n-1}} \phi(t) + \frac{n \overline{n-1}}{1 \cdot 2} \frac{1}{t^{n-2}} \phi(t) - \frac{n \overline{n-1} \overline{n-2}}{1 \cdot 2 \cdot 3} \frac{1}{t^{n-3}} \phi(t) + \&c.;$$

but since $\frac{1}{t^n} \phi(t)$ is the generating function of u_{x+n} , and $\frac{1}{t^{n-1}} \phi(t)$ that of u_{x+n-1} , &c. this expansion will be the generating function of

$$u_{x+n} - n u_{x+n-1} + \frac{n \overline{n-1}}{1 \cdot 2} u_{x+n-2} - \frac{n \overline{n-1} \overline{n-2}}{1 \cdot 2 \cdot 3} u_{x+n-3} + \&c.,$$

as well as of $\Delta^n u_x$. Hence, since quantities that have the same generating functions are equal,

$$\Delta^n u_x = u_{x+n} - n u_{x+n-1} + \frac{n \overline{n-1}}{1 \cdot 2} u_{x+n-2} - \frac{n \overline{n-1} \overline{n-2}}{1 \cdot 2 \cdot 3} u_{x+n-3} + \&c.$$

(147.) Again, since the generating function of u_{x+n} is $\frac{1}{t^n} \phi(t)$; and since $\frac{1}{t^n} = \left(1 + \frac{1}{t} - 1 \right)^n$;

$$\begin{aligned} \therefore \frac{1}{t^n} \phi(t) &= \phi(t) + n \cdot \left(\frac{1}{t} - 1 \right) \phi(t) + \frac{n \overline{n-1}}{1 \cdot 2} \left(\frac{1}{t} - 1 \right)^2 \phi(t) \\ &+ \frac{n \overline{n-1} \overline{n-2}}{1 \cdot 2 \cdot 3} \left(\frac{1}{t} - 1 \right)^3 \phi(t) + \&c. \end{aligned}$$

But $\phi(t)$ is the generating function of u_x , and $\left(\frac{1}{t} - 1 \right) \phi(t)$ is that of Δu_x , $\left(\frac{1}{t} - 1 \right)^2 \phi(t)$ that of $\Delta^2 u_x$, &c.

Hence $\frac{1}{t^n} \phi(t)$ is not only the generating function of u_{x+n} , but also of

$$u_x + n \Delta u_x + \frac{n \cdot \overline{n-1}}{1 \cdot 2} \Delta^2 u_x + \frac{n \overline{n-1} \cdot \overline{n-2}}{1 \cdot 2 \cdot 3} \Delta^3 u_x + \&c.;$$

and therefore this last series is equal to u_{x+n} .

(148.) Again, we have seen that if

$$\nabla u_x = a u_x + b u_{x+1} + c u_{x+2} + \&c. + q \cdot u_{x+n},$$

the generating function of $\nabla^m u_x$ will be

$$\left(a + \frac{b}{t} + \frac{c}{t^2} + \frac{e}{t^3} + \&c. + \frac{q}{t^n} \right)^m \phi(t);$$

and if the polynomial be expanded, and each term be multiplied by $\phi(t)$, the generating function of $\nabla^m u_x$ will be of the form

$$a_0 \phi(t) + a_1 \frac{1}{t} \phi(t) + a_2 \frac{1}{t^2} \phi(t) + a_3 \frac{1}{t^3} \phi(t) + a_4 \frac{1}{t^4} \phi(t) + \&c.;$$

whence it is obvious that

$$\nabla^m u_x = a_0 u_x + a_1 u_{x+1} + a_2 u_{x+2} + a_3 u_{x+3} + \&c.$$

(149.) The series obtained in the preceding articles for u_{x+n} are useful in finding the value of that term, by means of other known terms, and as in this consists the theory of interpolation, we shall now obtain such series as are most useful for that purpose.

Calculus of
Finite
Differences.

(1.) Since $\frac{1}{t^n} \phi(t)$, which is the generating function of $u_{x+n} = \frac{1}{\left(1 - t \frac{1}{t} - 1\right)^n} \phi(t)$,

Calculus of
Finite
Differences.

which may be written

$$\begin{aligned} & \left(1 - t \frac{1}{t} - 1\right)^{-n} \phi(t), \\ &= \phi(t) + n \left(\frac{1}{t} - 1\right) \cdot t \phi(t) + \frac{n \overline{n+1}}{1 \cdot 2} \left(\frac{1}{t} - 1\right)^2 \cdot t^2 \phi(t) \\ & \quad + \frac{n \overline{n+1} \overline{n+2}}{1 \cdot 2 \cdot 3} \left(\frac{1}{t} - 1\right)^3 \cdot t^3 \phi(t) + \&c. \dots \end{aligned}$$

But $t \cdot \phi(t)$ is the generating function of u_{x-1} , and $\left(\frac{1}{t} - 1\right) t \cdot \phi(t)$ is that of Δu_{x-1} , and $\left(\frac{1}{t} - 1\right) \cdot t^2 \phi(t)$ that of $\Delta^2 u_{x-2}$, and $\left(\frac{1}{t} - 1\right)^n t^n \phi(t)$ that of $\Delta^n u_{x-n}$;

$$\begin{aligned} \therefore u_{x+n} &= u_x + n \cdot \Delta u_{x-1} + \frac{n \cdot \overline{n+1}}{1 \cdot 2} \Delta^2 u_{x-2} + \frac{n \overline{n+1} \overline{n+2}}{1 \cdot 2 \cdot 3} \Delta^3 u_{x-3} \\ & \quad + \&c.: \text{ see Herschell's Examples.} \end{aligned}$$

(150.) This theorem may, by an extension of the principle of separating the symbols of operation from those of quantity, assume a very remarkable form.

For considering u_x as a factor, and writing $u_{x-n} = u_x \cdot u_{-n}$, and considering u_{-n} as the representative of $\frac{1}{u^n}$.

$$\begin{aligned} \text{Then } u_{x+n} &= u_x \cdot \left\{ 1 + n \cdot \Delta \cdot u_{-1} + \frac{n \overline{n+1}}{2} \Delta^2 u_{-2} + \frac{n \overline{n+1} \overline{n+2}}{1 \cdot 2 \cdot 3} \Delta^3 u_{-3} + \&c. \right\} \\ &= u_x \left\{ 1 + n \frac{\Delta}{u} + \frac{n \overline{n+1}}{2} \frac{\Delta^2}{u^2} + \frac{n \overline{n+1} \overline{n+2}}{1 \cdot 2 \cdot 3} \frac{\Delta^3}{u^3} + \&c. \right\} \\ &= u_x \left(1 - \frac{\Delta}{u} \right)^{-n} = \frac{u_x}{\left(1 - \frac{\Delta}{u} \right)^n}; \end{aligned}$$

and in thus giving to the symbol u_{-n} a new interpretation, no error can arise if, when we expand $\left(1 - \frac{\Delta}{u} \right)^{-n}$, we remember that the powers of u are to be changed into negative suffixes.

(151.) Next let $\frac{1}{t} = 1 + \frac{\alpha}{t^r}$, and let u_{x+n} be required, of which the generating function is $\frac{1}{t^n} \cdot \phi(t)$.

Make $\frac{1}{t} = y$, $\therefore y = 1 + \alpha y^r$; and by Lagrange's theorem for the expansion of functions

$$\phi(t) \cdot y^n = \frac{\phi(t)}{t^n} = \left\{ 1 + n\alpha + \frac{n \overline{n+2r-1}}{1 \cdot 2} \cdot \alpha^2 + \frac{n \cdot \overline{n+3r-1} \cdot \overline{n+3r-2}}{1 \cdot 2 \cdot 3} \alpha^3 \right. \\ \left. + \frac{n \cdot \overline{n+4r-1} \cdot \overline{n+4r-2} \cdot \overline{n+4r-3}}{2 \cdot 3 \cdot 4} \alpha^4 + \&c. \right\} \phi(t).$$

And (α) being equal $t^r \cdot \left(\frac{1}{t} - 1\right)$, $\therefore \alpha \cdot \phi(t)$ is the generating function of $\Delta \cdot u_{x-r}$, and $\alpha^2 \phi(t)$, or $t^{2r} \cdot \left(\frac{1}{t} - 1\right)^2 \cdot \phi(t)$ is the generating function of $\Delta^2 \cdot u_{x-2r}$; $\alpha^3 \phi(t)$ that of $\Delta^3 u_{x-3r}$, &c.; and as $\frac{\phi(t)}{t^n}$ is that of u_{x+n} ,

$$\begin{aligned} \therefore u_{x+n} &= u_x + n \cdot \Delta \cdot u_{x-r} + \frac{n \cdot \overline{n+2r-1}}{1 \cdot 2} \cdot \Delta^2 u_{x-2r} + \frac{n \cdot \overline{n+3r-1} \cdot \overline{n+3r-2}}{2 \cdot 3} \Delta^3 u_{x-3r} \\ & \quad + \&c. \qquad \qquad \qquad + \&c. \end{aligned}$$

(152.) A more general method of interpolation will be found if we suppose $t \cdot \left(\frac{1}{t} - 1\right)^z = z$, and we find an expression for $\frac{1}{t^n}$ in a series arranged according to the powers of z .

It is clear that $\frac{1}{t^n}$ is the same thing as the coefficient of α^n in the developement of the fraction $\frac{1}{1 - \frac{\alpha}{t}}$.

Calculus of
Finite
Differences.

Multiplying numerator and denominator by $1 - \alpha \cdot t$, we have $\frac{1 - \alpha t}{1 - \alpha \left(t + \frac{1}{t}\right) + \alpha^2}$, which becomes,

Calculus of
Finite
Differences.

since

$$t \cdot \left(\frac{1}{t} - 1\right)^2 = z \text{ gives } \frac{1}{t} + t = z + 2,$$

$$\frac{1 - \alpha t}{1 - \alpha z - 2\alpha + \alpha^2} = \frac{1 - \alpha t}{(1 - \alpha)^2 - \alpha^2}.$$

But

$$\frac{1}{1 - \alpha^2 - \alpha z} = \frac{1}{(1 - \alpha)^2} + \frac{\alpha z}{(1 - \alpha)^4} + \frac{\alpha^2 z^2}{(1 - \alpha)^6} + \frac{\alpha^3 z^3}{(1 - \alpha)^8} + \&c.$$

And to find the whole coefficient of α^n , each of these fractions must be developed, and the coefficient of the required power in each separate expansion being found, the sum of these terms will give the object of our inquiry.

Now the coefficient of α^r in the expansion of $\frac{1}{(1 - \alpha)^s}$ or $(1 - \alpha)^{-s} = \frac{s \cdot s + 1 \cdot s + 2 \cdot \dots \cdot s + r - 1}{1 \cdot 2 \cdot 3 \cdot \dots \cdot r}$; whence the coefficient of α^n in the expansion of $\frac{1}{(1 - \alpha)^2}$ is $n + 1$; and in that of $\frac{\alpha}{(1 - \alpha)^4}$ is $\frac{n \cdot n + 1 \cdot n + 2}{1 \cdot 2 \cdot 3}$; in that of $\frac{\alpha^2}{(1 - \alpha)^6}$ is $\frac{n - 1 \cdot n \cdot n + 1 \cdot n + 2 \cdot n + 3}{1 \cdot 2 \cdot 3 \cdot 4 \cdot 5}$, &c.; and calling Z the coefficient of α^n , we have

$$\begin{aligned} Z &= n + 1 + \frac{n \cdot n + 1 \cdot n + 2}{1 \cdot 2 \cdot 3} z + \frac{n - 1 \cdot n \cdot n + 1 \cdot n + 2 \cdot n + 3}{2 \cdot 3 \cdot 4 \cdot 5} z^2 \\ &\quad + \frac{n - 2 \cdot n - 1 \cdot n \cdot n + 1 \cdot n + 2 \cdot n + 3 \cdot n + 4}{2 \cdot 3 \cdot 4 \cdot 5 \cdot 6 \cdot 7} z^3 + \&c. \\ &= n + 1 \left\{ 1 + \frac{(n + 1)^2 - 1}{2 \cdot 3} z + \frac{\{(n + 1)^2 - 1\} \{(n + 1)^2 - 4\}}{2 \cdot 3 \cdot 4 \cdot 5} z^2 + \&c. \right\}; \end{aligned}$$

and putting (n) instead of $(n + 1)$, and calling Z' the coefficient of α^n in the developement of $\frac{\alpha}{(1 - \alpha)^2 - \alpha z}$, we shall have

$$Z' = n \left\{ 1 + \frac{n^2 - 1}{2 \cdot 3} z + \frac{(n^2 - 1)(n^2 - 4)}{2 \cdot 3 \cdot 4 \cdot 5} z^2 + \frac{(n^2 - 1)(n^2 - 4)(n^2 - 9)}{2 \cdot 3 \cdot 4 \cdot 5 \cdot 6 \cdot 7} z^3 + \&c. \right\}.$$

But it is obvious that the coefficient of α^n in the developement of $\frac{1 - \alpha t}{(1 - \alpha)^2 - \alpha z}$ or $\frac{1}{(1 - \alpha)^2 - \alpha z} - \frac{\alpha t}{(1 - \alpha)^2 - \alpha z}$ is $Z - Z' t$, and consequently

$$\frac{\phi(t)}{t^n} = \phi(t) \{Z - Z' t\} = Z \cdot \phi(t) - Z' t \cdot \phi(t).$$

But $\frac{\phi(t)}{t^n}$ is the generating function of u_{x+n} ; and $z \phi(t)$, $z^2 \phi(t)$, &c., or $t \cdot \left(\frac{1}{t} - 1\right)^2 \phi(t)$, $t^2 \cdot \left(\frac{1}{t} - 1\right)^4 \phi(t)$, &c. are the generating functions of $\Delta^2 \cdot u_{x-1}$, $\Delta^4 u_{x-2}$, &c., while $t \phi(t)$, $z \cdot t \phi(t)$, $z^2 t \phi(t)$, &c., or $t \phi(t)$, $t^2 \left(\frac{1}{t} - 1\right)^2 \cdot \phi(t)$, $t^3 \cdot \left(\frac{1}{t} - 1\right)^4 \cdot \phi(t)$, &c., are those of u_{x-1} , $\Delta^2 u_{x-2}$, $\Delta^4 u_{x-3}$, &c., and therefore we have

$$\begin{aligned} u_{x+n} &= n + 1 \left\{ u_x + \frac{(n + 1)^2 - 1}{2 \cdot 3} \Delta^2 u_{x-1} + \frac{\{(n + 1)^2 - 1\} \{(n + 1)^2 - 4\}}{2 \cdot 3 \cdot 4 \cdot 5} \Delta^4 u_{x-2} + \&c. \right\} \\ &\quad - n \left\{ u_{x-1} + \frac{n^2 - 1}{2 \cdot 3} \Delta^2 u_{x-2} + \frac{(n^2 - 1)(n^2 - 4)}{2 \cdot 3 \cdot 4 \cdot 5} \Delta^4 u_{x-3} + \&c. \right\}. \end{aligned}$$

(153.) Other expressions for u_{x+n} may be deduced from the preceding value for $\frac{1}{t^n}$.

Let Z'' be the value of Z' when $(n - 1)$ is put for (n) or the value of Z when $(n - 2)$ is put for (n) : in this case we shall change the equation

$$\frac{1}{t^n} = Z - Z' t \text{ into } \frac{1}{t^{n-1}} = Z' - Z'' \cdot t;$$

whence $\frac{1}{t^n} = \frac{Z'}{t} - Z''$; or, adding the two values of $\frac{1}{t^n}$, and then dividing by 2,

$$\frac{1}{t^n} = \frac{1}{2} Z - \frac{1}{2} Z'' + \frac{1}{2} Z' \cdot \frac{1}{1 + t} + \frac{1}{t} - 1.$$

Calculus of
Finite
Differences.

$$\begin{aligned} \text{But } \frac{1}{2}(Z - Z'') &= \frac{1}{2} \cdot \left\{ n+1 + \frac{\overline{n+1} \cdot \overline{n} \cdot \overline{n+2}}{2 \cdot 3} \cdot z + \frac{\overline{n-1} \cdot \overline{n} \cdot \overline{n+1} \cdot \overline{n+2} \cdot \overline{n+3}}{1 \cdot 2 \cdot 3 \cdot 4 \cdot 5} z^2 + \&c. \right\} \\ &\quad - \frac{1}{2} \left\{ n-1 + \frac{\overline{n-2} \cdot \overline{n-1} \cdot \overline{n}}{2 \cdot 3} z + \frac{\overline{n-3} \cdot \overline{n-2} \cdot \overline{n-1} \cdot \overline{n} \cdot \overline{n+1}}{2 \cdot 3 \cdot 4 \cdot 5} z^2 + \&c. \right\} \\ &= 1 + \frac{n^2}{1 \cdot 2} z + \frac{n^2(n^2-1)}{2 \cdot 3 \cdot 4} z^2 + \frac{n^2 \cdot (n^2-1)(n^2-4)}{2 \cdot 3 \cdot 4 \cdot 5 \cdot 6} z^3 + \&c.; \end{aligned}$$

Calculus of
Finite
Differences.

and substituting for (z) its value $t \cdot \left(\frac{1}{t} - 1\right)$,

$$\begin{aligned} \therefore \frac{\phi(t)}{t^n} &= \phi(t) \cdot \left\{ 1 + \frac{n^2}{1 \cdot 2} \cdot t \cdot \left(\frac{1}{t} - 1\right) + \frac{n^2 \cdot (n^2-1)}{2 \cdot 3 \cdot 4} \cdot t^2 \cdot \left(\frac{1}{t} - 1\right)^2 + \&c. \right\} \\ &\quad + \frac{n}{2} \cdot \phi(t) \cdot \overline{1+t} \cdot \left\{ \left(\frac{1}{t} - 1\right) + \frac{n^2-1}{2 \cdot 3} \cdot t \cdot \left(\frac{1}{t} - 1\right)^2 + \frac{(n^2-1)(n^2-4)}{2 \cdot 3 \cdot 4 \cdot 5} \cdot t^2 \cdot \left(\frac{1}{t} - 1\right)^3 + \&c. \right\}; \end{aligned}$$

whence by passing from the generating functions to coefficients, and observing that $\phi(t) \cdot (1+t) = \phi(t) + t\phi(t)$ = generating functions of u_x and u_{x+1} ,

$$\begin{aligned} u_{x+n} &= u_x + \frac{n^2}{1 \cdot 2} \cdot \Delta^2 u_{x-1} + \frac{n^2 \cdot \overline{n^2-1}}{2 \cdot 3 \cdot 4} \cdot \Delta^4 u_{x-2} + \frac{n^2 \cdot (n^2-1) \cdot \overline{n^2-4}}{2 \cdot 3 \cdot 4 \cdot 5 \cdot 6} \cdot \Delta^6 u_{x-3} + \&c. \\ &\quad + \frac{n}{2} \cdot (\Delta u_x + \Delta u_{x-1}) + \frac{n}{2} \cdot \frac{n^2-1}{2 \cdot 3} \cdot (\Delta^3 u_{x-1} + \Delta^3 u_{x-2}) \\ &\quad + \frac{n}{2} \cdot \frac{(n^2-1)(n^2-4)}{2 \cdot 3 \cdot 4 \cdot 5} (\Delta^5 u_{x-2} + \Delta^5 u_{x-3}) + \&c. \end{aligned}$$

(154.) This formula is useful to interpolate a term between an unequal number $2x+1$ of equidistant quantities, the common interval of which is unity: u_x is the middle term, the series being $u_0, u_1, u_2, \&c. u_x, u_{x+1}, \dots, u_{2x}$, and (n) is the interval between u_x and u_{x+n} .

The values $\Delta^2 u_{x-1}, \Delta u_x + \Delta u_{x-1}, \&c.$, which are the same as $u_{x+1} - 2u_x + u_{x-1}, u_{x+1} - u_{x-1}, \&c.$, are symmetric in their form with regard to u_x , for the terms they involve are arranged at equal intervals before and after u_x .

If, instead of making u_x the middle term of the series, we suppose the terms to be arranged equally about u_0 , we must use negative indices on one side of u_0 , and the series will be $u_{-x}, u_{-x-1}, \dots, u_0, u_1, \dots, u_x$, and u_n will be a function of u_0 and of the differences of the preceding values $u_{-1}, u_{-2}, u_{-3}, \dots, \&c.$

(155.) In the last expression obtained for $\frac{\phi(t)}{t^n}$ write $\overline{n+1}$ for n , and then subtract $\frac{\phi(t)}{t^n}$ from it; the result will then be

$$\begin{aligned} \frac{\phi(t)}{t^{n+1}} - \frac{\phi(t)}{t^n} &= \frac{\phi(t)}{t^n} \cdot \left\{ \frac{1}{t} - 1 \right\} \\ &= \phi(t) \cdot \left\{ \frac{2n+1}{1 \cdot 2} \cdot t \left(\frac{1}{t} - 1\right) + \frac{(4n+2) \cdot \overline{n} \cdot \overline{n+1}}{2 \cdot 3 \cdot 4} \cdot t^2 \cdot \left(\frac{1}{t} - 1\right)^2 + \&c. \right\} \\ &\quad + \frac{\phi(t)}{2} \overline{1+t} \cdot \left\{ \left(\frac{1}{t} - 1\right) + \frac{n \cdot \overline{n+1}}{2} \cdot t \cdot \left(\frac{1}{t} - 1\right)^2 + \frac{\overline{n-1} \cdot \overline{n} \cdot \overline{n+1} \cdot \overline{n+2}}{2 \cdot 3 \cdot 4} \cdot t^2 \cdot \left(\frac{1}{t} - 1\right)^3 + \&c. \right\}; \end{aligned}$$

whence, dividing each side by $\frac{1}{t} - 1$, and transferring the lower line to the upper place,

$$\begin{aligned} \frac{\phi(t)}{t^n} &= \frac{\phi(t)}{2} \cdot (1+t) \left\{ 1 + \frac{n \cdot \overline{n+1}}{2} \cdot t \cdot \left(\frac{1}{t} - 1\right) + \frac{\overline{n-1} \cdot \overline{n} \cdot \overline{n+1} \cdot \overline{n+2}}{2 \cdot 3 \cdot 4} \cdot t^2 \cdot \left(\frac{1}{t} - 1\right)^2 + \&c. \right\} \\ &\quad + \left(n + \frac{1}{2}\right) \phi(t) \cdot \left(\frac{1}{t} - 1\right) \left\{ t + \frac{n \cdot \overline{n+1}}{2} \cdot t^2 \cdot \left(\frac{1}{t} - 1\right) + \frac{\overline{n-1} \cdot \overline{n} \cdot \overline{n+1} \cdot \overline{n+2}}{2 \cdot 3 \cdot 4 \cdot 5} \cdot t^3 \cdot \left(\frac{1}{t} - 1\right)^2 + \&c. \right\} \\ &= \frac{\phi(t)}{2} \overline{1+t} \left\{ 1 + \frac{\left\{ \left(n + \frac{1}{2}\right)^2 - \frac{1}{4} \right\}}{1 \cdot 2} \cdot t \cdot \left(\frac{1}{t} - 1\right) + \frac{\left\{ \left(n + \frac{1}{2}\right)^2 - \frac{1}{4} \right\} \left\{ \left(n + \frac{1}{2}\right)^2 - \frac{9}{4} \right\}}{2 \cdot 3 \cdot 4} \cdot t^2 \cdot \left(\frac{1}{t} - 1\right)^2 + \&c. \right\} \\ &\quad + \left(n + \frac{1}{2}\right) t \cdot \phi(t) \cdot \frac{1}{t} - 1 \left\{ 1 + \frac{\left(n + \frac{1}{2}\right)^2 - \frac{1}{4}}{1 \cdot 2} \cdot t^2 \cdot \left(\frac{1}{t} - 1\right) + \frac{\left\{ \left(n + \frac{1}{2}\right)^2 - \frac{1}{4} \right\} \left\{ \left(n + \frac{1}{2}\right)^2 - \frac{9}{4} \right\}}{2 \cdot 3 \cdot 4} \cdot t^3 \cdot \left(\frac{1}{t} - 1\right)^2 + \&c. \right\} \end{aligned}$$

And now passing to coefficients, since

$$\frac{\phi(t)}{2} (1+t) = \frac{1}{2} \{ \phi(t) + t\phi(t) \}$$

Calculus of and
Finite
Differences.

$$\frac{\phi(t)}{2} \cdot (1+t) \cdot t^r \cdot \left(\frac{1}{t} - 1\right)^{2r} = \frac{1}{2} \left\{ t^r \cdot \phi(t) \cdot \left(\frac{1}{t} - 1\right)^{2r} + t^{r+1} \cdot \phi(t) \left(\frac{1}{t} - 1\right)^{2r} \right\},$$

Calculus of
Finite
Differences.

and remembering that $t^r \cdot \phi(t) \left(\frac{1}{t} - 1\right)^{2r}$ is the generating function of $\Delta^{2r} \cdot u_{x-r}$, and $t^{r+1} \cdot \phi(t) \left(\frac{1}{t} - 1\right)^{2r}$ is that of $\Delta^{2r} \cdot u_{x-r-1}$, we shall have

$$\begin{aligned} u_{x+n} &= \frac{1}{2} (u_x + u_{x-1}) + \frac{\left(n + \frac{1}{2}\right)^2 - \frac{1}{4}}{1 \cdot 2} \cdot \frac{1}{2} \cdot \{\Delta^2 u_{x-1} + \Delta^2 u_{x-2}\} \\ &+ \frac{\left(n + \frac{1}{2}\right)^2 - \frac{1}{4} \cdot \left(n + \frac{1}{2}\right)^2 - \frac{9}{4}}{2 \cdot 3 \cdot 4} \cdot \frac{1}{2} \cdot \{\Delta^4 u_{x-2} + \Delta^4 u_{x-3}\} + \&c. \\ &+ n + \frac{1}{2} \left\{ \begin{aligned} &\Delta u_{x-1} + \frac{\left(n + \frac{1}{2}\right)^2 - \frac{1}{4}}{1 \cdot 2} \cdot \Delta^3 u_{x-2} \\ &+ \frac{\left(n + \frac{1}{2}\right)^2 - \frac{1}{4} \cdot \left(n + \frac{1}{2}\right)^2 - \frac{9}{4}}{2 \cdot 3 \cdot 4} \cdot \Delta^5 u_{x-3} + \&c. \end{aligned} \right\} \end{aligned}$$

(156.) This formula is used for interpolation when there is an equal number $2x$ of equidistant numbers. The two middle terms are y_{x-1} and y_x , (if we suppose y_0 to be the first term) and y_{2x-1} is the last term.

These two formulæ of interpolation were given by Stirling, but without demonstration. He probably arrived at his results by successive inductions. They might have been shown to be true in an earlier part of this Treatise, but we reserved them for a place where they could illustrate the application of the theory of generating functions.

We must refer the reader to the *Théorie Analytique des Probabilités* of Laplace, page 19, for other formulæ of interpolation more general than that which has been just obtained, as our space will not allow us to pursue this part of our subject further.

(157.) The results which we have already obtained show with what facility the theory of generating functions demonstrates the theorems of finite differences. We shall continue to give some important ones as examples of its use.

We readily see that, putting T for $\phi(t)$,

$$\begin{aligned} T \cdot \left(\frac{1}{t^n} - 1\right)^m &= T \cdot \left\{ \left(1 + \frac{1}{t} - 1\right)^n - 1 \right\}^m \\ &= T \left\{ n \cdot \left(\frac{1}{t} - 1\right) + \frac{n(n-1)}{2} \cdot \left(\frac{1}{t} - 1\right)^2 + \frac{n(n-1)(n-2)}{1 \cdot 2 \cdot 3} \left(\frac{1}{t} - 1\right)^3 + \&c. \right\} \end{aligned}$$

But $T \cdot \left(\frac{1}{t} - 1\right)$ is the generating function of $\Delta \cdot u_x$, $T \cdot \left(\frac{1}{t} - 1\right)^2$ is that of $\Delta^2 u_x$, &c; and thus it appears that $T \cdot \left\{ \left(1 + \frac{1}{t} - 1\right)^n - 1 \right\}^m$ is the generating function of $\{(1 + \Delta \cdot u_x)^n - 1\}^m$, taking care to remember that the powers of Δu_x , which arise from the expansion, are to be considered only as symbols of operation, and that when we meet with the term $\overline{\Delta \cdot u_x}^r$ we must write for it $\Delta^r \cdot u_x$.

But adverting to the left-hand side of the equation, we observe that $T \cdot \left(\frac{1}{t^n} - 1\right) = \frac{T}{t^n} - T$, which is the generating function of $u_{x+n} - u_x$: this may be written $\Delta' u_x$, where Δ' indicates that (n) is the increment of (x) , and therefore $T \cdot \left(\frac{1}{t^n} - 1\right)^2$ is the generating function of $\Delta'^2 u_x$, (x) still increasing by (n) , and hence $T \cdot \left(\frac{1}{t^n} - 1\right)^m$ will be the generating function of $\Delta'^m \cdot u_x$; whence we conclude that

$$\Delta'^m u_x = \{(1 + \Delta \cdot u_x)^n - 1\}^m \quad (1)$$

If the symbol Σ' represent the finite integral, when x increases by the number n , or relative to differences indicated by Δ' , then it is evident that $\Sigma'^m u_x$ will have for its generating function the expression $T \cdot \left(\frac{1}{t^n} - 1\right)^{-m}$, the constants not being taken into account; but we have

$$T \left(\frac{1}{t^n} - 1\right)^{-m} = T \left\{ \left(1 + \frac{1}{t} - 1\right)^n - 1 \right\}^{-m};$$

whence we may conclude that

$$\Sigma'^m \cdot u_x = \{(1 + \Delta \cdot u_x)^n - 1\}^{-m}, \quad (2)$$

Calculus of Finite Differences. observing to change the negative powers of $\Delta \cdot u_x$ into terms of the form $\Sigma u_x, \Sigma^2 u_x, \&c.$: this last formula is implicitly contained in the preceding, since putting $(-m)$ for (m) we may change $\Delta'^{-m} u_x$ into $\Sigma'^m u_x$. (158.) These equations will also be true if we suppose that (x) , instead of increasing by unity in Δu_x , should increase by another quantity, as (k) , provided that the increase of (x) in $\Delta' u_x$ is (nk) . For if (x) be changed

into $\left(\frac{x_1}{k}\right)$, then when (x) increases by unity, $x_1 = kx$ will increase by (k) , and if (x) become $(x+n)$, (x_1) will become $(kx + kn)$, or will increase by (kn) ; or we may consider x to become $x+k$ with regard to the symbol Δ , and $x+nk$ with respect to the symbol Δ' .

If now we consider k to be a very small quantity, or dx , and (n) to be infinitely great, so that nk or ndx may be finite $= \alpha$, and that k is very small, therefore $\Delta u_x = d \cdot u_x$, we shall have

$$\Delta'^m \cdot u_x = \{(1 + d \cdot u_x)^n - 1\}^m$$

$$\Sigma'^m u_x = \{(1 + d \cdot u_x)^n - 1\}^{-m}.$$

But $\log(1 + d \cdot u_x)^n = n \log(1 + d \cdot u_x) = n \cdot d \cdot u_x = \alpha \frac{d \cdot u_x}{dx}$;

omitting the other terms of $\log(1 + d \cdot u_x)$, since k is infinitely small,

$$\therefore (1 + d \cdot u_x)^n = e^{\alpha \frac{d \cdot u_x}{dx}};$$

whence, substituting, we have

$$\Delta'^m \cdot u_x = (e^{\alpha \frac{d \cdot u_x}{dx}} - 1)^m \quad (3)$$

$$\Sigma'^m u_x = \frac{1}{(e^{\alpha \frac{d \cdot u_x}{dx}} - 1)^m}, \quad (4)$$

taking care to transfer to the symbol d the exponents of $d \cdot u_x$, and to change the negative powers into integrals.

If we had considered (n) to be infinitely small and $= dx$, then $\Delta'^m u_x$ will become $d^m u_x$, and $\Sigma'^m u_x$ will become $\frac{1}{d^m} \int^m u_x \cdot dx^m$, and

$$(1 + \Delta \cdot u_x)^n = (1 + \Delta \cdot u_x)^{dx} = e^{dx \cdot \log(1 + \Delta \cdot u_x)} = 1 + dx \cdot \log(1 + \Delta \cdot u_x);$$

and substituting this value for $(1 + \Delta u_x)^n$, equations (1) and (2) become

$$\frac{d^m u_x}{dx^m} = \{\log(1 + \Delta \cdot u_x)\}^m \quad (5)$$

$$\int^m u_x \cdot dx^m = \{\log(1 + \Delta \cdot u_x)\}^{-m}. \quad (6)$$

(159.) At present we have only considered a single function u_x ; the theory may, however, be extended to the case in which the product of many functions is concerned, and then some remarkable theorems may be easily deduced.

Let

T be the function of (t) when u_x is the coefficient of t^x

$T' \dots \dots \dots t' \dots \dots \dots u'_x \dots \dots \dots t'^x$

$T'' \dots \dots \dots t'' \dots \dots \dots u''_x \dots \dots \dots t''^x$

We shall, therefore, have $u_x, u'_x, u''_x, \&c.$ for the coefficient of $t^x, t'^x, t''^x, \&c.$ in the developement of the product $T \cdot T' T'' \dots$: this product will therefore be the generating function of $u_x, u'_x, u''_x \dots$; and, consequently, the

generating function of $u_{x+1} \cdot u'_{x+1} \cdot u''_{x+1}$ will be $\frac{T \cdot T' T'' \dots}{t \cdot t' \cdot t'' \dots}$; whence it follows that

$$\frac{T T' \cdot T'' \dots}{t \cdot t' \cdot t'' \dots} - T T' T'' \dots \left\{ \frac{1}{t \cdot t' \cdot t'' \dots} - 1 \right\}$$

is the generating function of

$$u_{x+1} \cdot u'_{x+1} \cdot u''_{x+1} \dots - u_x u'_x u''_x \dots = \Delta \cdot u_x \cdot u'_x \cdot u''_x \dots;$$

and thus the generating function of

$$\Delta^n \cdot u_x u'_x u''_x \dots \&c. \text{ is } T \cdot T' \cdot T'' \dots \left\{ \frac{1}{t \cdot t' \cdot t'' \dots} - 1 \right\}^n.$$

And if (z) be the generating function of $\Sigma^n \cdot (u_x u'_x u''_x \&c.)$, then that of $\Delta^n \cdot \Sigma^n \cdot (u_x u'_x u''_x \dots)$ or of $u_x u'_x u''_x \&c.$ will be from the preceding $z \cdot \left(\frac{1}{t t' t'' \dots} - 1 \right)^n$, whence

$$T \cdot T' T'' \dots = z \cdot \left(\frac{1}{t \cdot t' \cdot t'' \dots} - 1 \right)^n; \therefore z = T \cdot T' T'' \dots \left\{ \frac{1}{t \cdot t' \cdot t'' \dots} - 1 \right\}^{-n},$$

which is the generating function of $\Sigma^n \cdot (u_x u'_x u''_x \dots)$.

(160.) Applying these results to the product of two functions, u_x and v_x , where v_x is the same as u'_x .

Then the generating function of $\Delta^n u_x v_x$ will be $T \cdot T' \cdot \left(\frac{1}{t t'} - 1 \right)^n$, which may be put under the form

Calculus of
Finite
Differences.

 Calculus of
Finite
Differences.

$$T \cdot T' \left\{ \left(\frac{1}{t} - 1 \right) + \frac{1}{t} \left(\frac{1}{t^1} - 1 \right) \right\}^n$$

$$= T T' \left\{ \left(\frac{1}{t} - 1 \right) + \frac{n}{t} \cdot \left(\frac{1}{t} - 1 \right)^{n-1} \cdot \left(\frac{1}{t^1} - 1 \right) \right.$$

$$\left. + \frac{n \cdot n - 1}{1 \cdot 2 \cdot t^2} \cdot \left(\frac{1}{t} - 1 \right)^{n-2} \cdot \left(\frac{1}{t^1} - 1 \right)^2 + \&c. \right\}$$

But from the preceding article we perceive that the products

$$T \cdot T' \cdot \left(\frac{1}{t} - 1 \right)^n = T' \cdot T \left(\frac{1}{t} - 1 \right)^n$$

$$T \cdot T' \cdot \frac{1}{t} \left(\frac{1}{t} - 1 \right)^{n-1} \cdot \left(\frac{1}{t^1} - 1 \right) = T' \cdot \left(\frac{1}{t^1} - 1 \right) \cdot \frac{T}{t} \cdot \left(\frac{1}{t} - 1 \right)^{n-1}$$

$$T \cdot T' \cdot \frac{1}{t^2} \cdot \left(\frac{1}{t} - 1 \right)^{n-2} \cdot \left(\frac{1}{t^1} - 1 \right)^2 = T' \cdot \left(\frac{1}{t^1} - 1 \right)^2 \cdot \frac{T}{t^2} \cdot \left(\frac{1}{t} - 1 \right)^{n-2}$$

$$\&c. \qquad \qquad \qquad = \&c.$$

are the generating functions respectively of the products $v_x \cdot \Delta^n u_x$, $\Delta v_x \cdot \Delta^{n-1} u_{x+1}$, $\Delta^2 v_x \cdot \Delta^{n-2} u_{x+2}$, &c. Whence passing from generating functions to coefficients,

$$\Delta^n (u_x \cdot v_x) = v_x \cdot \Delta^n u_x + n \cdot \Delta v_x \cdot \Delta^{n-1} u_{x+1} + \frac{n \cdot n - 1}{2} \cdot \Delta^2 v_x \cdot \Delta^{n-2} u_{x+2} + \&c.,$$

and changing (n) into $(-n)$, we shall obtain

$$\Sigma^n (u_x \cdot v_x) = v_x \cdot \Sigma^n u_x - n \Delta v_x \cdot \Sigma^{n+1} u_{x+1} + \frac{n \cdot n + 1}{1 \cdot 2} \cdot \Delta^2 v_x \cdot \Sigma^{n+2} u_{x+2} - \&c.,$$

formulae previously obtained by successive and laborious induction.

(161.) Again, since we may put

$$T \cdot T' T'' \cdot \left\{ \frac{1}{t \cdot t' t'' \dots} - 1 \right\}^n$$

$$= T T' T'' \dots \left\{ 1 + \frac{1}{t} - 1 \cdot 1 + \frac{1}{t'} - 1 \cdot 1 + \frac{1}{t''} - 1 \cdot \dots - 1 \right\}^n$$

we have

$$\Delta^n \cdot u_x u'_x u''_x \dots = \{ 1 + \Delta \cdot 1 + \Delta' \cdot 1 + \Delta'' \cdot \dots - 1 \}^n u_x \cdot u'_x u''_x \dots;$$

taking care that in each term of the development of the right-hand side of the equation we apply the symbol Δ to the variables which are marked with the same accent. Thus if we had but three variables, the term $\Delta^r \cdot u_x u'_x u''_x$ indicates $u'_x u''_x \cdot \Delta^r u_x$, and $\Delta^r \Delta' u_x u'_x u''_x$ is to be written $u''_x \Delta' u_x \cdot \Delta^r u'_x$.

If (n) be negative, the formula will be true for Σ^n .

$$(162.) \text{ Again, since } T T' T'' \cdot \left\{ \frac{1}{t^h \cdot t'^h \cdot t''^h \dots} - 1 \right\}^n$$

$$= T \cdot T' T'' \dots \left\{ \left(1 + \frac{1}{t} - 1 \right)^h \left(1 + \frac{1}{t'} - 1 \right)^h \left(1 + \frac{1}{t''} - 1 \right)^h \dots - 1 \right\}^n,$$

and indicating by $\Delta^h u_x u'_x u''_x \dots$, when x increases by h , we have

$$\Delta'^n \cdot u_x u'_x u''_x \dots = \{ (1 + \Delta)^h (1 + \Delta')^h (1 + \Delta'')^h \dots - 1 \}^n u_x u'_x u''_x \dots;$$

and if we change (n) into $(-n)$, we shall obtain the expression for Σ^n .

For further illustrations of this interesting subject we must refer to the Works of its author, Laplace, and to the third volume of the Differential Calculus of his commentator Lacroix, where the reader will find the theory extended to functions of two or a greater number of variables.

The Summation of Series.

(163.) By the sum of a series is meant, the sum of any given number of the terms $u_1 u_2 u_3 u_4 \dots$ &c. u_x , and we shall show that when the general term is known the summation depends upon the integration of an equation of finite differences.

Let S_x represent the sum of x terms of the series just referred to; or let

$$S_x = u_1 + u_2 + u_3 + u_4 + \&c. + u_x;$$

$$\therefore S_{x+1} = u_1 + u_2 + u_3 + u_4 + \&c. + u_x + u_{x+1};$$

$$\therefore S_{x+1} - S_x = \Delta \cdot S_x = u_{x+1};$$

and

$$\therefore S_x = \Sigma \cdot u_{x+1} + C;$$

Calculus of Finite Differences. and to find C , let $x = 0$ and let $S_0 = 0$, $\therefore \sum u_1 + C = 0$, $\therefore C = -\sum u_1$,
 $\therefore S_x = \sum u_{x+1} - \sum u_1$.

Calculus of Finite Differences.

Hence to find the sum of any series we must find the integral of the $(x+1)$ th term, and this properly corrected will give the sum required.

(164.) If the form of u_{x+1} be not at once evident, we may use the formula

$$u_{x+1} = u_1 + x \Delta u_1 + \frac{x(x-1)}{2} \Delta^2 u_1 + \frac{x(x-1)(x-2)}{1 \cdot 2 \cdot 3} \Delta^3 u_1 + \&c.,$$

which will give us the $x+1$ th term when one of the orders of differences vanishes. Sometimes, however, u_{x+1} can only be found in terms of the preceding terms of the series multiplied by constant quantities. This case will demand a separate investigation: in the following examples, however, the $(x+1)$ th term will be found without difficulty.

(1.) Sum the arithmetic series $a + \overline{a+b} + \overline{a+2b} + \overline{a+3b} + \&c. + \overline{a+x-1b}$.

Here

$$u_x = a + \overline{x-1b} \text{ and } u_{x+1} = a + \overline{xb};$$

$$\therefore S_x = \sum (a + \overline{xb}) = ax + \frac{x \cdot \overline{x-1}}{2} \cdot b + C.$$

$$\text{And if } x = 0, S_0 = 0; \therefore C = 0, \text{ and } S_x = ax + \frac{x \cdot \overline{x-1}}{2} \cdot b = (2a + \overline{x-1b}) \frac{x}{2}.$$

$$\text{Cor. If } a = 1 \text{ and } b = 1, \text{ then } 1 + 2 + 3 + 4 + \&c. + x = \frac{x \cdot \overline{x+1}}{2}.$$

(2.) Sum the geometric series $a + ar + ar^2 + ar^3 + \&c. + ar^{x-1}$.

Here

$$u_x = ar^{x-1}; \therefore u_{x+1} = ar^x;$$

$$\therefore S_x = \sum ar^x = a \sum r^x = a \frac{r^x}{r-1} + C.$$

$$\text{And if } x = 0, S_0 = 0; \therefore 0 = \frac{a}{r-1} + C; \therefore C = -\frac{a}{r-1};$$

$$\therefore S_x = a \frac{r^x}{r-1} - a \frac{1}{r-1} = a \cdot \frac{r^x - 1}{r-1}.$$

(3.) Sum the series $1^2 + 2^2 + 3^2 + 4^2 + \&c. + x^2$.

Here

$$S_x = \sum u_{x+1} = \sum (x+1)^2 = \sum .x \cdot \overline{x+1} + \sum \overline{x+1}$$

$$= \frac{\overline{x-1} \cdot x \cdot \overline{x+1}}{3} + \frac{x \cdot \overline{x+1}}{2} + C.$$

$$\text{And when } x = 0, S_0 = 0; \therefore C = 0;$$

$$\therefore S_x = x \cdot \overline{x+1} \cdot \left\{ \frac{x-1}{3} + \frac{1}{2} \right\} = \frac{2 \cdot \overline{x+1} \cdot x \cdot \overline{x+1}}{2 \cdot 3}.$$

(4.) Sum the series $1^3 + 2^3 + 3^3 + 4^3 + \&c. + x^3$

Here

$$u_{x+1} = (x+1)^3 = (x+1) \{ (x+1)^2 - 1 \} + \overline{x+1} = x \cdot \overline{x+1} \cdot \overline{x+2} + \overline{x+1};$$

$$\therefore S_x = \sum u_{x+1} = \frac{\overline{x-1} \cdot x \cdot \overline{x+1} \cdot \overline{x+2}}{4} + \frac{x \cdot \overline{x+1}}{2} + C \text{ and } C = 0;$$

$$\therefore S_x = \frac{x \cdot \overline{x+1}}{2} \cdot \left(\frac{\overline{x-1} \cdot \overline{x+2}}{2} + 1 \right) = \frac{x \cdot \overline{x+1}}{2} \cdot \frac{x \cdot \overline{x+1}}{2} = \left(\frac{x \cdot \overline{x+1}}{2} \right)^2.$$

Hence

$$1^3 + 2^3 + 3^3 + 4^3 + \&c. + x^3 = (1 + 2 + 3 + 4 + \&c. + x)^2,$$

a result to which we have previously alluded.

(5.) To find the sum of the terms of any order of the figurate numbers.

The series

$$1 + 1 + 1 + 1 + 1 + 1 + \&c.$$

$$1 + 2 + 3 + 4 + 5 + 6 + 7 + \&c.$$

$$1 + 3 + 6 + 10 + 15 + 21 + 28 + \&c.$$

&c.

are called figurate series of the first, second, third, &c. order; it will be easily observed in these three series that the x th term of the second order is the sum of (x) terms of the first order: and the same rule is true for the third order. Hence we have this definition, the x th term of any order of figurate numbers is the sum of x terms of the preceding order.

$$\text{In the first order } u_{x+1} = 1; \therefore \sum .u_{x+1} = x;$$

$$\therefore \text{In the second order } u_{x+1} = x + 1, \text{ and } \sum u_{x+1} = \frac{x \cdot \overline{x+1}}{2}$$

Calculus of
Finite
Differences.

Calculus of
Finite
Differences.

$$\therefore \text{In the third order } u_{x+1} = \frac{x+1 \overline{x+2}}{2}; \therefore \Sigma u_{x+1} = \frac{x \overline{x+1} \overline{x+2}}{2 \cdot 3};$$

$$\therefore \text{In the fourth order } u_{x+1} = \frac{x+1 \overline{x+2} \overline{x+3}}{1 \cdot 2 \cdot 3}; \therefore \Sigma u_{x+1} = \frac{x \cdot x+1 \overline{x+2} \overline{x+3}}{2 \cdot 3 \cdot 4}.$$

And thus we might proceed to find the sum of the terms of any order of figurate numbers, and thus it is obvious that the sum of (x) terms of the n th order will be expressed by

$$S_x = \frac{x \cdot x+1 \overline{x+2} \overline{x+3} \dots \overline{x+n-1}}{1 \cdot 2 \cdot 3 \cdot 4 \dots n}.$$

(6.) Sum the series $1 \cdot 2 \cdot 4 + 2 \cdot 3 \cdot 5 + 3 \cdot 4 \cdot 6 + 4 \cdot 5 \cdot 7 + \&c.$

Here

$$\begin{aligned} u_x &= x \cdot x+1 \cdot x+3 = x \overline{x+1} \cdot x+2 + x \cdot x+1; \\ \therefore S_x &= \Sigma u_{x+1} \\ &= \Sigma (x+1 \overline{x+2} \cdot x+3) + \Sigma (x+1 \overline{x+2}) \\ &= \frac{x \overline{x+1} \overline{x+2} \overline{x+3}}{4} + \frac{x \overline{x+1} \overline{x+2}}{3} + C \text{ and } C=0 \\ &= \frac{x \overline{x+1} \overline{x+2} \cdot 3x+13}{3 \cdot 4}. \end{aligned}$$

(7.) Sum the series $3 \cdot 5 \cdot 7 + 5 \cdot 7 \cdot 9 + 7 \cdot 9 \cdot 11 + \&c.$

Here

$$u_x = (2x+1) \cdot (2x+3) (2x+5);$$

$$\therefore S_x = \Sigma u_{x+1} = \Sigma \{2x+3 \cdot 2x+5 \cdot 2x+7\} = \frac{2x+1 \overline{2x+3} \overline{2x+5} \cdot 2x+7}{2 \cdot 4} + C;$$

and

$$x=0 \text{ gives } C = -\frac{1 \cdot 3 \cdot 5 \cdot 7}{2 \cdot 4};$$

$$\therefore S_x = \frac{2x+1 \overline{2x+3} \overline{2x+5} \overline{2x+7} - 1 \cdot 3 \cdot 5 \cdot 7}{2 \cdot 4}.$$

(8.) Sum the series $\frac{1}{1 \cdot 2 \cdot 3} + \frac{1}{2 \cdot 3 \cdot 4} + \frac{1}{3 \cdot 4 \cdot 5} + \&c.$

Here

$$u_x = \frac{1}{x \cdot x+1 \overline{x+2}}; \therefore u_{x+1} = \frac{1}{x+1 \overline{x+2} \cdot x+3};$$

$$\therefore S_x = \Sigma u_{x+1} = -\frac{1}{2x+1 \overline{x+2}} + C,$$

and

$$0 = \Sigma u_1 = -\frac{1}{4} + C;$$

$$\therefore S_x = \frac{1}{4} - \frac{1}{2 \cdot x+1 \overline{x+2}}.$$

And if S = the sum of an infinite series, we have in this case $S = \frac{1}{4}$.

(9.) Sum the series $\frac{5}{2 \cdot 3 \cdot 4 \cdot 5} + \frac{8}{3 \cdot 4 \cdot 5 \cdot 6} + \frac{11}{4 \cdot 5 \cdot 6 \cdot 7} + \&c.$ The general term of $5+8+11+\&c.$ is $3x+2$;

$$\begin{aligned} \therefore u_x &= \frac{3x+2}{x+1 \cdot x+2 \overline{x+3} \overline{x+4}} = \frac{3(x+4) - 10}{x+1 \overline{x+2} \overline{x+3} \overline{x+4}} \\ &= \frac{3}{x+1 \overline{x+2} \overline{x+3}} - \frac{10}{x+1 \overline{x+2} \overline{x+3} \cdot x+4}; \\ \therefore S_x &= \Sigma u_{x+1} + C = C - \frac{3}{2 \cdot x+2 \overline{x+3}} + \frac{10}{3 \cdot x+2 \overline{x+3} \overline{x+4}} \\ \therefore 0 &= \Sigma u_1 + C = C - \frac{3}{12} + \frac{10}{3 \cdot 24} = C - \frac{1}{4} + \frac{5}{36}; \therefore C = \frac{1}{9}. \\ S_x &= \frac{1}{9} - \frac{3}{2 \cdot x+2 \overline{x+3}} + \frac{10}{3 \cdot x+2 \cdot x+3 \overline{x+4}} \\ &= \frac{1}{9} - \frac{9x+16}{6 \cdot x+2 \overline{x+3} \cdot x+4}, \text{ and } S = \frac{1}{9}. \end{aligned}$$

Calculus of
Finite
Differences.(10.) Sum $\frac{1}{1 \cdot 3} + \frac{1}{3 \cdot 5} + \frac{1}{5 \cdot 7} + \&c.$

Here

$$u_x = \frac{1}{(2x-1)(2x+1)}; \therefore u_{x+1} = \frac{1}{2x+1 \cdot 2x+3};$$

$$\therefore S_x = \sum u_{x+1} + C = C - \frac{1}{2(2x+1)}, \text{ and } C = +\frac{1}{2};$$

$$\therefore S_x = \frac{1}{2} - \frac{1}{2(2x+1)}; \therefore S = \frac{1}{2}.$$

(11.) Sum the series $1 + 2a + 3a^2 + 4a^3 + \&c. + xa^{x-1}.$

Here

$$u_x = xa^{x-1}; \therefore u_{x+1} = (x+1)a^x = x \cdot a^x + a^x;$$

$$\therefore \sum u_{x+1} = \sum x \cdot a^x + \sum a^x = x \cdot \frac{a^x}{a-1} - \sum \frac{a^{x+1}}{a-1} + \frac{a^x}{a-1} + C$$

$$= \frac{xa^x}{a-1} + \frac{a^x}{a-1} - \frac{a \cdot a^x}{(a-1)^2} + C.$$

And if

$$x=0; \therefore 0 = \frac{1}{a-1} - \frac{a}{(a-1)^2} + C; \therefore C = \frac{1}{(a-1)^2};$$

$$\therefore S_x = \frac{1+a^x(ax-x-1)}{(a-1)^2}; \text{ if } (a) \text{ be a fraction, } S = \frac{1}{(a-1)^2}.$$

(12.) Sum $2 \cdot 5 \cdot 8 + 4 \cdot 8 \cdot 14 + 8 \cdot 14 \cdot 26 + 16 \cdot 26 \cdot 50 + \&c.$

Here

$$u_x = 2^x \cdot (3 \cdot 2^{x-1} + 2)(3 \cdot 2^x + 2);$$

$$\therefore u_{x+1} = 2^{x+1} \cdot (3 \cdot 2^x + 2)(3 \cdot 2^{x+1} + 2)$$

$$= 2 \cdot 2^x \cdot (3 \cdot 2^x + 2)(3 \cdot 2^{x+1} + 2);$$

$$\therefore \sum u_{x+1} = 2 \cdot \sum 2^x (3 \cdot 2^x + 2)(3 \cdot 2^{x+1} + 2).$$

But

$$\therefore \sum a^x \cdot (pa^x + q)(pa^{x+1} + q) = a \cdot \frac{pa^{x-1} + q \cdot pa^x + q \cdot pa^{x+1} + q}{p(a^3 - 1)};$$

$$\therefore S_x = C + 4 \cdot \frac{(3 \cdot 2^{x-1} + 2) \cdot (3 \cdot 2^x + 2) \cdot (3 \cdot 2^{x+1} + 2)}{3 \cdot 7}$$

$$= C + 4 \cdot \frac{27 \cdot 2^{3x} + 63 \cdot 2^{2x} + 42 \cdot 2^x + 8}{3 \cdot 7}, \text{ and } C = -4 \cdot \frac{132}{3 \cdot 7}$$

$$= 4 \cdot \frac{9 \cdot 2^{3x} + 21 \cdot 2^{2x} + 14 \cdot 2^x - 44}{7}$$

$$= \frac{36 \cdot 2^{3x} + 84 \cdot 2^{2x} + 56 \cdot 2^x - 176}{7}.$$

The law of such series as $5 + 8 + 14 + 26 + \&c.$, where the differences are the same, may be found by the following artifice.

Since

$$u_0 = 5, \Delta u_0 = 3, \Delta^2 u_0 = 3, \Delta^3 u_0 = 3, \&c.$$

$$\therefore u_x = 5 + 3 \cdot \overline{x-1} + 3 \cdot \frac{x-1 \cdot x-2}{1 \cdot 2} + \frac{3 \cdot \overline{x-1} \cdot x-2 \cdot x-3}{1 \cdot 2 \cdot 3} + \&c.$$

$$= 5 + 3 \cdot \left(1 + \overline{x-1} + \frac{x-1 \cdot x-1}{1 \cdot 2} + \&c. \dots - 1 \right)$$

$$= 5 + 3 \{ \overline{1+1}^{x-1} - 1 \} = 5 + 3 \cdot (2^{x-1} - 1) = 3 \cdot 2^{x-1} + 2.$$

The summation of many series may be effected by analytical artifices, some of which we subjoin.

(13.) Sum $\frac{1^3 \cdot 4}{2 \cdot 3} + \frac{2^3 \cdot 4^2}{3 \cdot 4} + \frac{3^3 \cdot 4^3}{4 \cdot 5} + \frac{4^3 \cdot 4^4}{5 \cdot 6} + \&c.$

Here

$$u_x = \frac{x^3 \cdot 4^x}{(x+1) \cdot (x+2)}.$$

Now

$$\Delta \cdot \frac{x-2}{x+1} 4^x = \frac{x-1 \cdot 4^{x+1}}{x+2} - \frac{x-2}{x+1} 4^x = 4^x \left(\frac{4 \cdot x-1}{x+2} - \frac{x-2}{x+1} \right)$$

$$= \frac{3x^2 \cdot 4^x}{x+1 \cdot x+2};$$

$$\text{i.e. } u_x = \frac{1}{3} \Delta \cdot \frac{x-2}{x+1} \cdot 4^x; \therefore u_{x+1} = \frac{1}{3} \Delta \cdot \frac{x-1}{x+2} \cdot 4^{x+1}$$

Calculus of
Finite
Differences.

Calculus of
Finite
Differences.

Calculus of
Finite
Differences.

$$\therefore S_x = \sum u_{x+1} = \frac{1}{3} \frac{4^{x+1} \cdot x - 1}{x + 2} + C; \therefore C = \frac{2}{3},$$

$$S_x = \frac{2}{3} + \frac{4}{3} 4^x \cdot \frac{x - 1}{x + 2}.$$

$$(14.) \text{ Sum } \frac{5}{1 \cdot 2 \cdot 3} \cdot \frac{1}{2} + \frac{6}{2 \cdot 3 \cdot 4} \cdot \frac{1}{2^2} + \frac{7}{3 \cdot 4 \cdot 5} \cdot \frac{1}{2^3} + \&c.$$

Here

$$u_x = \frac{x + 4}{x \cdot x + 1 \cdot x + 2} \cdot \frac{1}{2^x}.$$

And since

$$\begin{aligned} \Delta \cdot \frac{1}{x \cdot x + 1 \cdot 2^{x-1}} &= \frac{1}{x + 1 \cdot x + 2 \cdot 2^x} - \frac{1}{x \cdot x + 1 \cdot 2^{x-1}} \\ &= \frac{x - 2x - 4}{x \cdot x + 1 \cdot x + 2 \cdot 2^x} = -\frac{x + 4}{x \cdot x + 1 \cdot x + 2 \cdot 2^x}; \end{aligned}$$

$$\therefore u_x = -\Delta \frac{1}{x \cdot x + 1 \cdot 2^{x-1}}; \therefore u_{x+1} = -\Delta \frac{1}{x + 1 \cdot x + 2 \cdot 2^x};$$

$$\therefore S_x = C - \frac{1}{x + 1 \cdot x + 2 \cdot 2^x} = \frac{1}{2} - \frac{1}{x + 1 \cdot x + 2 \cdot 2^x}; \therefore S = \frac{1}{2}.$$

$$(15.) \text{ Sum the series } \frac{3}{5 \cdot 7} - \frac{9}{7 \cdot 29} + \frac{27}{29 \cdot 79} - \frac{81}{79 \cdot 245} + \&c.$$

Here

$$u_x = \frac{(-3)^x}{\{2 - (-3)^x\} \{2 - (-3)^{x+1}\}}.$$

And to integrate this expression we observe that, as

$$\begin{aligned} \Delta \cdot \frac{1}{\beta - \alpha^x} &= \frac{1}{\beta - \alpha^{x+1}} - \frac{1}{\beta - \alpha^x} = \frac{\alpha^x \cdot (\alpha - 1)}{(\beta - \alpha^x) \cdot (\beta - \alpha^{x+1})}, \\ \therefore \frac{\alpha^x}{(\beta - \alpha^x) \cdot (\beta - \alpha^{x+1})} &= \frac{1}{\alpha - 1} \Delta \cdot \frac{1}{\beta - \alpha^x}. \end{aligned}$$

Hence by making $\beta = 2$ and $\alpha = -3$,

$$\therefore u_x = -\frac{1}{4} \Delta \frac{1}{2 - (-3)^x};$$

$$\therefore S_x = \sum u_{x+1} = C - \frac{1}{4} \cdot \frac{1}{2 - (-3)^{x+1}};$$

and making

$$x = 0, \therefore 0 = C - \frac{1}{4 \cdot 5}, \therefore C = \frac{1}{20},$$

$$\therefore S_x = \frac{1}{20} - \frac{1}{4} \cdot \frac{1}{2 - (-3)^{x+1}} = \frac{1}{4} \cdot \left\{ \frac{1}{5} - \frac{1}{2 - (-3)^{x+1}} \right\}, \text{ and } S = \frac{1}{20}.$$

$$(16.) \text{ Sum the series } \frac{1}{1 \cdot 3 \cdot 5 \cdot 7} + \frac{2}{5 \cdot 7 \cdot 9 \cdot 11} + \frac{3}{9 \cdot 11 \cdot 13 \cdot 15} + \&c.$$

Here

$$u_x = \frac{x}{(4x - 3)(4x - 1)(4x + 1)(4x + 3)}.$$

In this example the difference between the successive terms of the denominator being only 2 instead of 4, the ordinary rule will not apply, and we must have recourse to the following method.

Since

$$\Delta \cdot \frac{1}{z_x v_x} = \frac{1}{z_{x+1} \cdot v_{x+1}} - \frac{1}{z_x v_x} = -\frac{z_x \Delta v_x + v_x \Delta z_x + \Delta v_x \cdot \Delta z_x}{z_x v_x \cdot z_{x+1} \cdot v_{x+1}},$$

assume
and

$$z_x = 4x - 3; \therefore z_{x+1} = 4x + 1; \therefore \Delta z_x = 4,$$

$$v_x = 4x - 1; \therefore v_{x+1} = 4x + 3; \therefore \Delta v_x = 4;$$

$$\therefore z_x \Delta v_x + v_x \Delta z_x + \Delta v_x \cdot \Delta z_x = 16x - 12 + 16x - 4 + 16 = 32 \cdot x;$$

$$\therefore \frac{x}{(4x - 3)(4x - 1)(4x + 1)(4x + 3)} = -\frac{1}{32} \cdot \Delta \cdot \frac{1}{(4x - 3) \cdot (4x - 1)};$$

$$\therefore S_x = \sum u_{x+1} + C = C - \frac{1}{32} \cdot \frac{1}{4x + 1 \cdot 4x + 3}.$$

Calculus of
Finite
Differences.

Make

$$x = 0; \therefore C = \frac{1}{96};$$

$$\therefore S_x = \frac{1}{32} \left\{ \frac{1}{3} - \frac{1}{(4x+1)(4x+3)} \right\}, \text{ and } S = \frac{1}{96}.$$

(17.) Sum the series $\sin \theta + \sin(\theta + h) + \sin(\theta + 2h) + \&c. + \sin(\theta + \overline{x-1}h)$.

Here
and

$$u_x = \sin(\theta + \overline{x-1}h); \therefore u_{x+1} = \sin(\theta + xh),$$

$$\Sigma u_{x+1} = \Sigma \sin(\theta + xh).$$

Now

$$\begin{aligned} \Delta \cos(\theta + zh) &= \cos(\theta + \overline{z+1}h) - \cos(\theta + zh) \\ &= -2 \sin \frac{h}{2} \cdot \sin\left(\theta + \frac{2z+1}{2}h\right); \end{aligned}$$

$$\therefore \sin\left(\theta + \frac{2z+1}{2}h\right) = -\frac{\Delta \cos(\theta + zh)}{2 \sin \frac{h}{2}}.$$

Make $\frac{2z+1}{2} = x; \therefore z = \frac{2x-1}{2}$; and integrating,

$$\therefore S_x = \Sigma \sin(\theta + xh) = C - \frac{\cos\left(\theta + \frac{2x-1}{2}h\right)}{2 \sin \frac{h}{2}}.$$

Make

$$x = 0; \therefore C = \frac{\cos\left(\theta - \frac{h}{2}\right)}{2 \sin \frac{h}{2}};$$

$$\therefore S_x = \frac{\cos\left(\theta - \frac{h}{2}\right) - \cos\left(\theta + \frac{2x-1}{2}h\right)}{2 \sin \frac{h}{2}} = \frac{\sin\left(\theta + \frac{x-1}{2}h\right) \cdot \sin \frac{xh}{2}}{\sin \frac{h}{2}}.$$

(18.) Similarly to sum the series $\cos \theta + \cos(\theta + h) + \&c. + \cos(\theta + \overline{x-1}h)$, we have to integrate $\cos(\theta + xh)$.

Now

$$\begin{aligned} \Delta \sin(\theta + zh) &= \sin(\theta + \overline{z+1}h) - \sin(\theta + zh) \\ &= 2 \sin \frac{h}{2} \cdot \cos\left(\theta + \frac{2z+1}{2}h\right); \end{aligned}$$

whence

$$\Sigma \cos(\theta + xh) = C + \frac{\sin\left(\theta + \frac{2x-1}{2}h\right)}{2 \sin \frac{h}{2}};$$

$$\therefore S_x = \frac{\sin\left(\theta + \frac{2x-1}{2}h\right) - \sin\left(\theta - \frac{h}{2}\right)}{2 \sin \frac{h}{2}} = \frac{\cos\left(\theta + \frac{x-1}{2}h\right) \cdot \sin \frac{xh}{2}}{\sin \frac{h}{2}}.$$

Cor. Make $h = 2\theta; \therefore \theta + \frac{x-1}{2}h = \theta + \overline{x-1}\theta = x\theta$, and $\frac{xh}{2} = x\theta$.

$$\therefore \sin \theta + \sin 3\theta + \sin 5\theta + \&c. + \sin \overline{2x-1}\theta = \frac{(\sin x\theta)^3}{\sin \theta},$$

and

$$\cos \theta + \cos 3\theta + \cos 5\theta + \&c. + \cos \overline{2x-1}\theta = \frac{\sin 2x\theta}{2 \sin \theta}.$$

(19.) Sum the series $1 + a \cos \theta + a^2 \cos 2\theta + a^3 \cos 3\theta + \&c. + a^{x-1} \cos \overline{x-1}\theta$.

Here

$$u_x = a^{x-1} \cos \overline{x-1}\theta \text{ and } u_{x+1} = a^x \cos x\theta.$$

Now

$$\Sigma a^x \cos x\theta = C + \frac{a^{x+1} \cos \overline{x+1}\theta - a^x \cos x\theta}{a^2 - 2a \cos \theta + 1}.$$

Calculus of
Finite
Differences.

Calculus of
Finite
Differences.

Make

$$x=0; \therefore C + \frac{a \cos \theta - 1}{a^2 - 2a \cos \theta + 1} = 0;$$

$$\therefore S_x = \frac{1 - a \cos \theta + a^{x+1} \cdot \cos x - 1 \theta - a^x \cos x \theta}{a^2 - 2a \cos \theta + 1};$$

and when $x = \infty$, (a) being a proper fraction,

$$S = \frac{1 - a \cos \theta}{a^2 - 2a \cos \theta + 1}.$$

Make

$$\theta = 0; \therefore S_x = \frac{1 - a + a^{x+1} - a^x}{(1 - a)^2} = \frac{1 - a - a^x(1 - a)}{(1 - a)^2} = \frac{1 - a^x}{1 - a},$$

and

$$S = \frac{1 - a}{a^2 - 2a + 1} = \frac{1 - a}{(1 - a)^2} = \frac{1}{1 - a}.$$

(165.) We have already mentioned *recurring series*, and have shown in what manner the general term u_x is to be found, and have seen that the solution of an equation of the first degree is necessary to find u_x : but as this equation has constant coefficients, the difficulty is resolved to the solution of an equation of common algebra.

Example. The scale of relation being $(p + q)$, find the general term and the sum of the series.

Here

Let

$$u_{x+2} = p u_{x+1} + q u_x.$$

$$u_x = a^x, \therefore a^2 = p a + q.$$

Let α and β be the roots of this equation, then α^x, β^x will be prime integrals of the original equation, and $\therefore u_x = C' \alpha^x + C'' \beta^x$ will be the complete solution. As the series is given, C' and C'' may be found by making $x = 1$ and $x = 2$, from the equations

$$u_1 = C' \alpha + C'' \beta \quad \text{Let } C' = A$$

$$u_2 = C' \alpha^2 + C'' \beta^2 \quad C'' = B$$

$$\therefore u_x = A \alpha^x + B \beta^x;$$

$$\therefore S_x = C + \sum u_{x+1} = C + A \alpha \frac{\alpha^x}{\alpha - 1} + B \beta \frac{\beta^x}{\beta - 1};$$

and C may be found by making $x = 0$, when also $S_x = 0$.

(166.) We have supposed the scale of relation to be merely $p + q$; but if it consisted of n terms, the mode of proceeding would be entirely the same, and the general term would be of the form

$$u_x = C_1 \alpha^x + C_2 \beta^x + C_3 \gamma^x + \&c. + C_n \nu^x,$$

and the series would be $\sum u_{x+1} + C$.

Example (1.) The scale of relation being $p + q$, find p and q , and the sum of the series $1 + 5 + 17 + 53 + 161 + \&c$.

Since

$$u_{x+2} = p u_{x+1} + q u_x;$$

$$\therefore 17 = 5p + q, \text{ and } 53 = 17p + 5q; \therefore p = 4 \text{ and } q = -3;$$

$$\therefore u_{x+2} = 4 u_{x+1} - 3 u_x.$$

$$u_x = a^x, \therefore a^2 = 4a - 3, \therefore a = 3 \text{ or } 1;$$

Make

and

$$u_x = C_1 3^x + C_2. \text{ Make } x = 1 \text{ and } 2 \text{ successively;}$$

$$\therefore 1 = 3C_1 + C_2 \text{ and } 5 = 9C_1 + C_2; \therefore C_1 = \frac{2}{3} \text{ and } C_2 = -1;$$

$$\therefore u_x = 2 \cdot 3^{x-1} - 1; \therefore u_{x+1} = 2 \cdot 3^x - 1;$$

$$\therefore S_x = C + 2 \cdot \frac{3^x}{3-1} - x = C + 3^x - x = 3^x - x - 1.$$

Example (2.) Find the scale of relation and the sum of the series

$$1 + 5a + 19a^2 + 65a^3 + 211a^4 + \&c. \dots$$

Here

$$\therefore 19a^2 = p \cdot 5a + q \text{ and } 65a^3 = p \cdot 19a^2 + 5a \cdot q;$$

and

$$\therefore 65a^2 = 19pa + 5q,$$

$$95a^2 = 25pa + 5q;$$

$$\therefore 30a^2 = 6pa; \therefore p = 5a \text{ and } q = 19a^2 - 25a^2 = -6a^2;$$

$$\therefore u_{x+2} = 5a u_{x+1} - 6a^2 u_x.$$

Make

$$u_x = m^x; \therefore m^2 - 5am + 6a^2 = 0; \therefore m = 2a \text{ and } 3a;$$

$$\therefore u_x = C_1 (2a)^x + C_2 (3a)^x;$$

$$\therefore 1 = 2C_1 a + 3C_2 a$$

$$5 = 4C_1 a + 9C_2 a;$$

whence

VOL. II.

Calculus of
Finite
Differences.

$$C_1 = -\frac{1}{a} \text{ and } C_2 = \frac{1}{a}; \therefore u_x = (3^x - 2^x) a^{x-1};$$

$$\begin{aligned} \therefore S_x = \sum u_{x+1} &= \sum 3^{x+1} \cdot a^x - \sum 2^{x+1} \cdot a^x + C \\ &= 3 \cdot \frac{(3a)^x}{3a-1} - 2 \cdot \frac{(2a)^x}{2a-1} + C; \end{aligned}$$

and when

$$\begin{aligned} x=0, C &= \frac{2}{2a-1} - \frac{3}{3a-1} = \frac{1}{1-5a+6a^2}; \\ \therefore S_x &= \frac{6a\{(3a)^x - (2a)^x\} - (3^{x+1} - 2^{x+1})a^x + 1}{1-5a+6a^2} \\ &= \frac{a^{x+1} \cdot (2 \cdot 3^{x+1} - 3 \cdot 2^{x+1}) - a^x \cdot (3^{x+1} - 2^{x+1}) + 1}{1-5a+6a^2}. \end{aligned}$$

Cor. We have here supposed the roots of the equation $a^2 = pa + q$ to be different; if they be equal, and each be $= \alpha$, we must put $u_x = (C' + C''x) \alpha^x$, and proceed as before to determine C' and C'' .

But then

$$\begin{aligned} S_x = \sum u_{x+1} &= \sum (C' + C''x) \alpha^{x+1} \\ &= C + C_1 \sum \alpha^x + C_2 \sum (x \alpha^x) \\ &= C + \frac{C_1 \alpha^x}{\alpha - 1} + C_2 \left(\frac{x \alpha^x}{\alpha - 1} - \frac{\alpha^{x+2}}{(\alpha - 1)^2} \right), \end{aligned}$$

where

$$C_1 = (C' + C'') \alpha, \text{ and } C_2 = C'' \alpha.$$

(167.) But it is not necessary to integrate the expression for u_{x+1} in order to find the sum of the series.

For

$$\therefore u_{x+2} = p u_{x+1} + q \cdot u_x;$$

$$\therefore u_{x+1} + \Delta u_{x+1} = p(u_x + \Delta u_x) + q u_x;$$

$$\therefore \Delta u_{x+1} + (1-p) \Delta u_x + (1-p-q) u_x = 0,$$

by putting $u_{x+1} + \Delta u_{x+1}$ for u_{x+2} and $u_x + \Delta u_x$ for u_{x+1} ;

$$\therefore \Delta \cdot u_{x+2} + (1-p) \Delta u_{x+1} + (1-p-q) u_{x+1} = 0;$$

$$\therefore u_{x+2} + (1-p) u_{x+1} + (1-p-q) \cdot \sum u_{x+1} = 0$$

$$S_x = \sum u_{x+1} = C - \frac{u_{x+2} + (1-p) u_{x+1}}{1-p-q};$$

$$\therefore 0 = C - \frac{u_2 + (1-p) u_1}{1-p-q};$$

$$\therefore S_x = - \frac{(u_{x+2} - u_2) + (1-p)(u_{x+1} - u_1)}{1-p-q}.$$

Application of the Integral Calculus to the Summation of Series.

(168.) As in many cases the value of an integral may be expressed by means of a series, therefore whenever the value of the integral can either be entirely or approximately found the sum of the series can also be found.

Now it is easily seen that

$$\int \frac{dx}{1+x} = x - \frac{x^2}{2} + \frac{x^3}{3} - \frac{x^4}{4} + \frac{x^5}{5} - \&c.$$

$$\int \frac{dx}{1+x^2} = x - \frac{x^3}{3} + \frac{x^5}{5} - \frac{x^7}{7} + \frac{x^9}{9} - \&c.$$

$$\int \frac{dx}{\sqrt{1-x^2}} = x + \frac{1}{2} \cdot \frac{x^3}{3} + \frac{1 \cdot 3}{2 \cdot 4} \frac{x^5}{5} + \frac{1 \cdot 3 \cdot 5}{2 \cdot 4 \cdot 6} \frac{x^7}{7} + \&c.$$

And since $\int \frac{dx}{1+x} = \log(1+x)$; $\int \frac{dx}{1+x^2} = \tan^{-1}x$; and $\int \frac{dx}{\sqrt{1-x^2}} = \sin^{-1}x$: we have, by integrating between the limits of $x=0$ and $x=1$,

$$\log(2) = 1 - \frac{1}{2} + \frac{1}{3} - \frac{1}{4} + \frac{1}{5} - \frac{1}{6} + \frac{1}{7} - \&c.$$

$$\frac{\pi}{4} = 1 - \frac{1}{3} + \frac{1}{5} - \frac{1}{7} + \frac{1}{9} - \frac{1}{11} + \&c.$$

$$\frac{\pi}{2} = 1 + \frac{1}{2} \cdot \frac{1}{3} + \frac{1 \cdot 3}{2 \cdot 4} \cdot \frac{1}{5} + \frac{1 \cdot 3 \cdot 5}{2 \cdot 4 \cdot 6} \cdot \frac{1}{7} + \&c.$$

Calculus of
Finite
Differences.

and since the approximate values of $\log(2)$ and π are known, the sums of the series of which they are the representatives are also known.

Calculus of
Finite
Differences.

(169.) Also, as we can arrive at the values of certain series, as for instance the sum of the inverse powers of the natural numbers, by other processes than by integration, and as these series can be produced by means of an integral, we can assume the value of the integral to be represented by the sum of these series, and, by a combination of the values of known series and known integrals, the sum of many series may be found which it would be difficult to determine by other means.

(170.) Series of this kind are the following:

$$\frac{1}{1 \cdot 2^2 \cdot 3^2} + \frac{1}{2 \cdot 3^2 \cdot 4^2} + \frac{1}{3 \cdot 4^2 \cdot 5^2} + \&c. \text{ to infinity,}$$

$$\frac{1}{2 \cdot 1^2} + \frac{1}{3 \cdot 2^2} + \frac{1}{4 \cdot 3^2} + \&c.,$$

which are dependent partly upon the sum of

$$\frac{1}{1^2} + \frac{1}{2^2} + \frac{1}{3^2} + \frac{1}{4^2} + \&c. = \frac{\pi^2}{6},$$

and known integrals. We easily see that the last series may be represented by an integral.

For

$$\int \frac{dx}{1-x} = \frac{x}{1} + \frac{x^2}{2} + \frac{x^3}{3} + \frac{x^4}{4} + \frac{x^5}{5} + \&c.;$$

$$\therefore \int \frac{dx}{x} \cdot \int \frac{dx}{1-x} = \frac{x}{1^2} + \frac{x^2}{2^2} + \frac{x^3}{3^2} + \frac{x^4}{4^2} + \&c.;$$

and $\therefore \int \frac{dx}{x} \cdot \int \frac{dx}{1-x}$ integrated from $x=0$ to $x=1$, is equal to $\frac{\pi^2}{6}$.

Thus also $\int \frac{dx}{x} \int \frac{dx}{1+x}$, which produces the series $\frac{x}{1} - \frac{x^2}{2^2} + \frac{x^3}{3^2} - \&c.$ is, when taken between the limits of $x=0$ and $x=1$, equal to $\frac{\pi^2}{12}$.

(171.) But before we attend to examples of this kind we will explain a method first given by Euler, by which the sum of many series may be found, and the methods are of very general application.

To take a very simple instance, let

$$s = x + 2x^2 + 3x^3 + 4x^4 + \&c. \dots + nx^n.$$

Then multiplying by $\frac{dx}{x}$, and performing the integrations, to get rid of the coefficients,

$$\int \frac{s dx}{x} = x + x^2 + x^3 + x^4 + x^5 + \&c. + x^n = \frac{x - x^{n+1}}{1-x};$$

whence, by differentiation,

$$\frac{s}{x} = \frac{1 - n + 1 \cdot x^n + n \cdot x^{n+1}}{(1-x)^2}; \therefore s = \frac{x - n + 1 x^{n+1} + n x^{n+2}}{(1-x)^2}.$$

(172.) Again, suppose

$$s = \frac{x}{2} + \frac{2}{3}x^2 + \frac{3}{4}x^3 + \frac{4}{5}x^4 + \&c. \text{ to infinity;}$$

$$\therefore sx = \frac{x^2}{2} + \frac{2x^3}{3} + \frac{3x^4}{4} + \frac{4x^5}{5} + \&c.;$$

$$\therefore \frac{d(sx)}{dx} = x + 2x^2 + 3x^3 + 4x^4 + \&c.$$

And multiplying each side by $\frac{dx}{x}$, and integrating, we shall get rid of the numerical coefficients, and

$$\int \frac{dx}{x} \cdot \frac{d}{dx}(sx) = x + x^2 + x^3 + x^4 + \&c. = \frac{x}{1-x};$$

$$\therefore \frac{1}{x} \cdot \frac{d}{dx}(sx) = \frac{1}{(1-x)^2}, \text{ or } sx = \int \frac{x dx}{(1-x)^2};$$

whence

$$s = \frac{1}{x} \cdot \left\{ C + \frac{1}{1-x} + \log(1-x) \right\};$$

and since, when $x=0$, $s=0$, and $\therefore sx=0$, $\therefore C+1=0$ or $C=-1$;

$$\therefore s = \frac{1}{x} \cdot \left\{ \frac{x}{1-x} + \log(1-x) \right\} = \frac{1}{1-x} + \frac{\log(1-x)}{x}.$$

Calculus of Finite Differences. And the value of the series may be computed whenever x is < 1 ; but if $x = 1$, the series will be infinitely great. Calculus of Finite Differences.

For

$$s = \frac{x + (1-x) \cdot \log(1-x)}{x(1-x)} = \frac{x + \log \sqrt{1-x}}{x(1-x)} = \infty, \text{ if } x = 1.$$

(173.) The method contained in the preceding article will apply to the summation of those series of which the general term is $\frac{A x^n}{B}$, where A and B are rational and integral functions of n resolved into factors of the first degree. The factors of the numerator are made to disappear by successive integrations, and those of the denominator by successive differentiation.

Let $\frac{\alpha + n\beta}{a + nb} x^n$ be the general term of the series

$$s = \frac{\alpha + \beta}{a + b} x + \frac{\alpha + 2\beta}{a + 2b} x^2 + \frac{\alpha + 3\beta}{a + 3b} x^3 + \&c. + \frac{\alpha + n\beta}{a + nb} x^n.$$

Multiply each term by $p x^r$, and differentiate,

$$\therefore p \cdot \frac{d \cdot (s x^r)}{dx} = (\alpha + \beta) \frac{p r + p}{a + b} x^r + \&c. + (\alpha + n\beta) \frac{(p r + p n)}{a + nb} x^{n+r-1};$$

and by making $p = b$, and $p r = a$, or $r = \frac{a}{b}$, the factors of the form $\frac{p r + p n}{a + nb}$ may be made equal to unity, and we shall have

$$b \cdot \frac{d}{dx} (s \cdot x^{\frac{a}{b}}) = (\alpha + \beta) \cdot x^{\frac{a}{b}} + (\alpha + 2\beta) x^{\frac{a}{b}+1} + \&c. + (\alpha + n\beta) \cdot x^{\frac{a}{b}+n-1}.$$

Again, multiplying every term by $p x^r \cdot dx$, and integrating each term, the integral of the general term will be

$$\frac{b p (\alpha + n\beta) \cdot x^{n+r+\frac{a}{b}}}{a + b r + b n};$$

and the factor $\frac{b p (\alpha + n\beta)}{a + b r + b n}$ may be made to disappear by making $a b p = a + b r$, and $b p \beta = b$, or $p = \frac{1}{\beta}$;

$$\therefore r = \frac{a}{\beta} - \frac{a}{b};$$

$$\begin{aligned} \therefore \frac{b}{\beta} \cdot \int \{x^{\frac{a}{\beta}-\frac{a}{b}} \cdot d \cdot (s x^{\frac{a}{b}})\} &= x^{\frac{a}{\beta}+1} + x^{\frac{a}{\beta}+2} + x^{\frac{a}{\beta}+3} + \&c. + x^{\frac{a}{\beta}+n} \\ &= x^{\frac{a}{\beta}+1} \cdot \left(\frac{1-x^n}{1-x} \right) = X \text{ by substitution;} \end{aligned}$$

whence

$$\begin{aligned} d \cdot (s x^{\frac{a}{b}}) &= \frac{\beta}{b} \cdot x^{\frac{a}{b}-\frac{a}{\beta}} \cdot d \cdot X; \\ \therefore s &= \frac{\beta \cdot \int \cdot x^{\frac{a}{b}-\frac{a}{\beta}} \cdot d X}{b x^{\frac{a}{b}}} = \frac{\beta \cdot \int x^{\frac{a}{b}-\frac{a}{\beta}} \cdot d \left\{ \frac{1-x^n}{1-x} \cdot x^{\frac{a}{\beta}+1} \right\}}{b x^{\frac{a}{b}}} \end{aligned}$$

The integral of which must be taken from $x = 0$ to $x = x$.

A similar method will apply whenever the coefficient of x^n contains a greater number of simple factors in the numerator and the denominator; but as the plan is after the previous investigation sufficiently obvious, we pass on to another class of series.

(174.) In the series considered in the preceding articles, the number of the factors either in the numerator or denominator is the same for every term. But there is a class to which the name of hypergeometric has been given by Euler, in which this number increases from one term to the other. The series

$$\frac{\alpha + \beta}{a + b} x + \frac{(\alpha + \beta)(\alpha + 2\beta)}{(a + b)(a + 2b)} x^2 + \&c. + \frac{(\alpha + \beta)(\alpha + 2\beta) \dots (\alpha + n\beta)}{(a + b)(a + 2b) \dots (a + nb)} x^n$$

is of this class, the summation of which (as we shall see) will require the integration of a differential equation.

In the first instance, however, we shall show how the most simple case of this class of series may be reduced to an equation from which (s) is to be deduced.

Let $s = (\alpha + \beta) x + (\alpha + \beta)(\alpha + 2\beta) x^2 + \&c. + (\alpha + \beta) \cdot (\alpha + 2\beta) \dots (\alpha + n\beta) x^n$.

Multiplying each term by $p \cdot x^r \cdot dx$, and integrating, we have

$$p \int s x^r \cdot dx = \frac{p \cdot (\alpha + \beta) \cdot x^{r+2}}{r + 2} + \&c. + \frac{p (\alpha + \beta)(\alpha + 2\beta) \dots (\alpha + n\beta)}{n + r + 1} x^{n+r+1}.$$

Let $p(\alpha + n\beta) = n + r + 1$; $\therefore p = \frac{1}{\beta}$, and $p\alpha = r + 1$; $\therefore r = \frac{\alpha}{\beta} - 1$;

Calculus of
Finite
Differences.

Calculus of
Finite
Differences.

$$\therefore \frac{1}{\beta} \cdot \int s x^{\frac{\alpha}{\beta}-1} \cdot dx = x^{\frac{\alpha}{\beta}+1} + (\alpha + \beta) x^{\frac{\alpha}{\beta}+2} + \&c. + (\alpha + \beta) \dots (\alpha + n - 1 \beta) \cdot x^{\frac{\alpha}{\beta}+n};$$

whence, dividing by $x^{\frac{\alpha}{\beta}+1}$, and subtracting unity from each side,

$$\frac{\frac{1}{\beta} \cdot \int s \cdot x^{\frac{\alpha}{\beta}-1} \cdot dx}{x^{\frac{\alpha}{\beta}+1}} - 1 = (\alpha + \beta) x + (\alpha + \beta) (\alpha + 2 \beta) x^2 + \&c. + (\alpha + \beta) \dots (\alpha + n - 1 \beta) x^{n-1}$$

$$= s - (\alpha + \beta) \cdot (\alpha + 2 \beta) \dots (\alpha + n \beta) x^n = s - A x^n,$$

where

$$A = (\alpha + \beta) \cdot (\alpha + 2 \beta) \dots (\alpha + n \beta);$$

whence

$$\int s x^{\frac{\alpha}{\beta}-1} dx = \beta \cdot x^{\frac{\alpha}{\beta}+1} \{1 + s - A \cdot x^n\};$$

whence, by differentiation, we shall, after reduction, find that

$$\beta x^2 \cdot \frac{ds}{dx} + (\alpha + \beta \cdot x - 1) s = (n \beta + \alpha + \beta) A \cdot x^{n+1} - (\alpha + \beta) x.$$

A similar method will apply where the number of factors in each successive coefficient increase by two or by any greater number.

(175.) Next let us take the series in which the factors are in the denominator only; so that

$$s = \frac{x}{\alpha + \beta} + \frac{x^2}{(\alpha + \beta)(\alpha + 2 \beta)} + \&c. + \frac{x^n}{(\alpha + \beta)(\alpha + 2 \beta) \dots (\alpha + n \beta)}.$$

Multiply by $p x^r$, and then differentiate;

$$\therefore p \cdot \frac{d \cdot (s x^r)}{dx} = \frac{p(r+1)x^r}{\alpha + \beta} + \&c. + \frac{p(n+r) \cdot x^{n+r-1}}{(\alpha + \beta)(\alpha + 2 \beta) \dots (\alpha + n \beta)};$$

and making $p n = \beta n$ and $p r = \alpha$, whence $p = \beta$ and $r = \frac{\alpha}{\beta}$;

$$\therefore \frac{\beta \frac{d}{dx} \cdot (s x^{\frac{\alpha}{\beta}})}{x^{\frac{\alpha}{\beta}}} - 1 = \frac{x}{\alpha + \beta} + \&c. + \frac{x^{n-1}}{(\alpha + \beta) \dots (\alpha + n - 1 \beta)} = s - \frac{x^n}{A},$$

whence

$$\frac{ds}{dx} + \frac{\beta - x}{\beta x} s = \frac{A - x^n}{A \beta};$$

a linear equation, the integration of which gives

$$s = \frac{1}{\beta} \cdot e^{\frac{x}{\beta}} x^{-\frac{\alpha}{\beta}} \int e^{-\frac{x}{\beta}} \cdot x^{\frac{\alpha}{\beta}} \left(\frac{A - x^n}{A} \right) dx.$$

(176.) Lastly, if the factors be found both in the numerator and denominator, or if

$$s = \frac{a + b}{\alpha + \beta} x + \frac{(a + b)(a + 2b)}{(\alpha + \beta)(\alpha + 2 \beta)} x^2 + \&c. + \frac{(a + b)(a + 2b) \dots (a + nb)}{(\alpha + \beta)(\alpha + 2 \beta) \dots (\alpha + n \beta)} x^n$$

Multiplying by $p x^r \cdot dx$, and integrating,

$$p \cdot \int s x^r dx = \frac{p(a+b)}{(r+2)(\alpha+\beta)} x^{r+2} + \&c. \dots + \frac{p(a+b)(a+nb)}{(r+n+1)(\alpha+\beta) \dots (\alpha+n\beta)} x^{n+r+1}.$$

Let $p(a+nb) = r+n+1$; $\therefore pb = 1$, and $pa = r+1$; $\therefore p = \frac{1}{b}$ and $r = \frac{a}{b} - 1 = \frac{a-b}{b}$;

$$\therefore \frac{1}{b} \int s x^{\frac{a-b}{b}} dx = \frac{x^{\frac{a-b}{b}+1}}{\alpha + \beta} + \&c. + \frac{(a+b) \dots (a+n-1b)}{(\alpha + \beta) \dots (\alpha + n \beta)} x^{\frac{a-b}{b}+n}.$$

For $\frac{1}{b} \int s x^{\frac{a-b}{b}} dx$ put S , and again multiply by $p x^r$, and differentiate;

$$\therefore p \frac{d \cdot (S x^r)}{dx} = \frac{p \left(\frac{a}{b} + r + 1 \right) x^{\frac{a-b}{b}+r}}{\alpha + \beta} + \dots + \frac{p \cdot \left(\frac{a}{b} + n + r \right) (a+b) \dots (a+n-1b)}{(\alpha + \beta) \dots (\alpha + n \beta)} x^{\frac{a-b}{b}+n+r-1};$$

Let $p \left(\frac{a}{b} + n + r \right) = \alpha + n \beta$; $\therefore p = \beta$, and $p \cdot \left(\frac{a}{b} + r \right) = \alpha$; $\therefore r = \frac{\alpha}{\beta} - \frac{a}{b}$;

$$\therefore \frac{\beta}{b} \cdot \frac{d}{dx} \cdot \left\{ x^{\frac{a-b}{b}} \cdot \int s x^{\frac{a-b}{b}} dx \right\} = \left\{ 1 + s - \frac{(a+b) \dots (a+nb)}{(\alpha + \beta) \dots (\alpha + n \beta)} x^n \right\} x^{\frac{a-b}{b}}.$$

Calculus of
Finite
Differences.

(177.) As an example, find the sum of the series

$$s = \frac{1}{3}x + \frac{1 \cdot 2}{3 \cdot 4}x^2 + \frac{1 \cdot 2 \cdot 3}{3 \cdot 4 \cdot 5}x^3 + \frac{1 \cdot 2 \cdot 3 \cdot 4}{3 \cdot 4 \cdot 5 \cdot 6}x^4 + \&c.$$

Here $a = 0$, $b = 1$; $\alpha + \beta = 3$, $\beta = 1$; $\therefore \alpha = 2$; whence

$$\frac{d}{dx} \left\{ x^2 \cdot \int \frac{s}{x} dx \right\} = \left(1 + s - \frac{x^n}{n+1} \right) x^2.$$

If we suppose the series to consist of an infinite number of terms, and x not greater than unity, the term $\frac{x^n}{n+1}$ may be neglected;

$$\therefore \frac{d}{dx} \left\{ x^2 \cdot \int \frac{s}{x} dx \right\} = x^2 (1 + s);$$

$$\therefore 2x \int \frac{s}{x} dx + sx = x^2 + x^2 s;$$

$$\therefore (x-1) \frac{ds}{dx} = s \left(\frac{2}{x} - 1 \right) - 1;$$

$$\therefore \frac{ds}{dx} + s \cdot \frac{x-2}{x(x-1)} = -\frac{1}{x-1};$$

a linear equation, in which $e^{\int \frac{x-2}{x(x-1)} dx} = \frac{x^2}{x-1}$;

$$\therefore s = \frac{x-1}{x^2} \left\{ C - \int \frac{x^2 dx}{(x-1)^2} \right\} = \frac{x-1}{x^2} \left\{ C + \frac{1+x-x^2}{x-1} - \log(x-1)^2 \right\};$$

and $\therefore$ when $x = 0$, $s = 0$; $\therefore C = 1$;

$$\therefore s = \frac{x-1}{x^2} \left\{ \frac{2x-x^2}{x-1} - \log(x-1)^2 \right\} = \frac{2-x}{x} - \frac{x-1}{x^2} \log(x-1)^2.$$

If $x = 1$, $s = 1$; or $\frac{1}{3} + \frac{1 \cdot 2}{3 \cdot 4} + \frac{1 \cdot 2 \cdot 3}{3 \cdot 4 \cdot 5} + \&c.$ to infinity $= 1$.

(178.) If in the preceding expressions $(-x)$ be written for x , we shall find equations for the sum of series in which the terms are alternately positive and negative; but as the first term will be negative, we must change (s) into $(-s)$, if we deduce the value of the series from the foregoing investigation.

As an example, let us take the infinite series

$$s = 1 \cdot x - 1 \cdot 2x^2 + 1 \cdot 2 \cdot 3x^3 - 2 \cdot 3 \cdot 4x^4 + \&c.,$$

which compared with

$$(\alpha + \beta)x - (\alpha + \beta)(\alpha + 2\beta)x^2 + (\alpha + \beta)(\alpha + 2\beta)(\alpha + 3\beta)x^3 - \&c.$$

gives $\alpha = 0$, $\beta = 1$, and putting $(-x)$ for (x) , and $(-s)$ for (s) , the equation

$$\beta x^2 \cdot \frac{ds}{dx} + (\alpha + \beta \cdot x - 1)s = (n\beta + \alpha + \beta)Ax^{n+1} - (\alpha + \beta)x$$

becomes

$$x^2 \frac{ds}{dx} + (x+1)s = x, \text{ or } \frac{ds}{dx} + \frac{x+1}{x^2}s = \frac{1}{x};$$

the integral of which may be found, since it is a linear equation, by multiplying both sides of the equation by $xe^{-\frac{1}{x}}$;

$$\therefore sxe^{\frac{1}{x}} = \int e^{-\frac{1}{x}} dx; \therefore s = \frac{e^{\frac{1}{x}}}{x} \cdot \int e^{-\frac{1}{x}} dx,$$

in which the integral must be taken from $x = 0$ to $x = x$.

(179.) Similarly we might arrive at the value of (s) when

$$s = x - 1 \cdot x^2 + 1 \cdot 2x^3 - 1 \cdot 2 \cdot 3x^4 + \&c.;$$

but more directly by the following process. Differentiating

$$\frac{ds}{dx} = 1 - 2 \cdot x + 2 \cdot 3x^2 - 2 \cdot 3 \cdot 4x^3 + \&c.$$

$$\therefore x^2 \frac{ds}{dx} = x^2 - 2 \cdot x^3 + 2 \cdot 3x^4 - 2 \cdot 3 \cdot 4x^5 + \&c. = x - s$$

$$\therefore \frac{ds}{dx} + \frac{s}{x^2} = \frac{1}{x}.$$

Calculus of
Finite
Differences.

Calculus of
Finite
Differences.

Multiply by $e^{-\frac{1}{x}}$, and integrate,

$$\therefore s e^{-\frac{1}{x}} = \int \frac{e^{-\frac{1}{x}}}{x} dx; \therefore s = e^{\frac{1}{x}} \cdot \int \frac{e^{-\frac{1}{x}}}{x} dx;$$

which, integrated between the limits of $x = 0$ and $x = 1$, gives the sum of the series $1 - 1 + 1 \cdot 2 - 1 \cdot 2 \cdot 3 + 1 \cdot 2 \cdot 3 \cdot 4 - \&c.$

The value of the integral $\int \frac{e^{-\frac{1}{x}}}{x} dx$ cannot, however, be exactly computed, but Euler has given a series by which its value may be approximately found, the error being scarcely appreciable.

(180.) We proceed to give some applications of the theory laid down in the preceding articles.

Thus, if it be required to sum the series

$$\frac{1}{1 \cdot 3} \pm \frac{1}{3 \cdot 5} + \frac{1}{5 \cdot 7} \pm \frac{1}{7 \cdot 9} + \&c$$

Let

$$s = \frac{x^3}{1 \cdot 3} \pm \frac{x^5}{3 \cdot 5} + \frac{x^7}{5 \cdot 7} \pm \frac{x^9}{7 \cdot 9} + \&c;$$

$$\therefore \frac{ds}{dx} = \frac{x^2}{1} \pm \frac{x^4}{3} + \frac{x^6}{5} \pm \frac{x^8}{7} + \&c;$$

$$\therefore \frac{d}{dx} \cdot \left(\frac{1}{x} \cdot \frac{ds}{dx} \right) = 1 \pm x^2 + x^4 \pm x^6 + \&c$$

$$= \frac{1}{1 \mp x^2};$$

$$\therefore \frac{1}{x} \frac{ds}{dx} = \int \frac{dx}{1 \mp x^2}, \text{ and } s = \int x dx \cdot \int \frac{dx}{1 \mp x^2}.$$

1. Taking the upper sign,

$$s = \frac{x^2}{2} \int \frac{dx}{1-x^2} - \frac{1}{2} \int \frac{x^2 dx}{1-x^2} = \left(\frac{x^2-1}{2} \right) \log \sqrt{\frac{1+x}{1-x}} + \frac{x}{2},$$

which, integrated from $x = 0$ to $x = 1$, gives $s = \frac{1}{2}$.

2. Taking the lower sign,

$$s = \frac{x^2}{2} \int \frac{dx}{1+x^2} - \frac{1}{2} \int \frac{x^2 dx}{1+x^2} = \left(\frac{x^2+1}{2} \right) \tan^{-1} x - \frac{x}{2};$$

whence $s = \frac{\pi}{4} - \frac{1}{2}$, if the integral be taken from $x = 0$ to $x = 1$; or

$$\frac{1}{1 \cdot 3} + \frac{1}{3 \cdot 5} + \frac{1}{5 \cdot 7} + \frac{1}{7 \cdot 9} + \&c. \text{ to infinity} = \frac{1}{2}$$

$$\frac{1}{1 \cdot 3} - \frac{1}{3 \cdot 5} + \frac{1}{5 \cdot 7} - \frac{1}{7 \cdot 9} + \&c. = \frac{\pi}{4} - \frac{1}{2}$$

and $\therefore$

$$\frac{1}{1 \cdot 3} + \frac{1}{5 \cdot 7} + \frac{1}{9 \cdot 11} + \&c. = \frac{\pi}{8}.$$

(181.) Next to sum the series $\frac{1}{1 \cdot 2} + \frac{1}{4 \cdot 5} + \frac{1}{7 \cdot 8} + \frac{1}{10 \cdot 11} + \&c. \text{ to infinity.}$

Let

$$s = \frac{x^2}{1 \cdot 2} + \frac{x^5}{4 \cdot 5} + \frac{x^8}{7 \cdot 8} + \frac{x^{11}}{10 \cdot 11} + \&c;$$

$$\therefore \frac{ds}{dx} = \frac{x}{1} + \frac{x^4}{4} + \frac{x^7}{7} + \frac{x^{10}}{10} + \&c;$$

$$\therefore \frac{d}{dx} \cdot \left(\frac{ds}{dx} \right) = 1 + x^3 + x^6 + x^9 + \&c. = \frac{1}{1-x^3};$$

$$\therefore \frac{ds}{dx} = \int \frac{dx}{1-x^3}, \text{ and } s = \int dx \cdot \int \frac{dx}{1-x^3},$$

which, integrated from $x = 0$ to $x = 1$, will give the sum required.

Now

$$\int dx \int \frac{dx}{1-x^3} = x \int \frac{dx}{1-x^3} - \int \frac{x dx}{1-x^3}$$

$$= \frac{1-x}{3} \cdot \log \frac{1-x}{\sqrt{1+x+x^2}} - \frac{1-x}{3\sqrt{3}} \tan^{-1} \frac{x\sqrt{3}}{2+x} + \frac{2}{\sqrt{3}} \tan^{-1} \frac{2x+1}{\sqrt{3}};$$

Calculus of
Finite
Differences.

Calculus of
Finite
Differences.

whence

$$s = \frac{1}{1 \cdot 2} + \frac{1}{4 \cdot 5} + \frac{1}{7 \cdot 8} + \&c. = \frac{2\pi}{3\sqrt{3}}.$$

(182.) Again, sum $\frac{1}{1 \cdot 3} - \frac{1}{2 \cdot 4} + \frac{1}{3 \cdot 5} - \frac{1}{4 \cdot 6} + \&c.$

Let

$$s = \frac{x^3}{1 \cdot 3} - \frac{x^4}{2 \cdot 4} + \frac{x^5}{3 \cdot 5} - \frac{x^6}{4 \cdot 6} + \&c.$$

$$\therefore \frac{ds}{dx} = \frac{x^2}{1} - \frac{x^3}{2} + \frac{x^4}{3} - \frac{x^5}{4} + \&c.;$$

$$\therefore \frac{d}{dx} \cdot \left(\frac{1}{x} \cdot \frac{ds}{dx} \right) = 1 - x + x^2 - x^3 + \&c. = \frac{1}{1+x};$$

$$\therefore \frac{1}{x} \frac{ds}{dx} = \int \frac{dx}{1+x}, \text{ and } s = \int x dx \int \frac{dx}{1+x};$$

$$\therefore s = \frac{x^2}{2} \cdot \log(1+x) - \frac{1}{2} \cdot \int \frac{x^2 dx}{1+x} = \left(\frac{x^2-1}{2} \right) \log(1+x) - \frac{(1-x)^2}{4},$$

which, integrated from $x=0$ to $x=1$, gives $S = \frac{1}{4}$.

(183.) To sum the series $\frac{1}{2 \cdot 1^2} + \frac{1}{3 \cdot 2^2} + \frac{1}{4 \cdot 3^2} + \frac{1}{5 \cdot 4^2} + \&c.$ to infinity.

Let

$$s = \frac{x^3}{2 \cdot 1^2} + \frac{x^4}{3 \cdot 2^2} + \frac{x^5}{4 \cdot 3^2} + \frac{x^6}{5 \cdot 4^2} + \&c.;$$

$$\therefore \frac{ds}{dx} = \frac{x}{1^2} + \frac{x^2}{2^2} + \frac{x^3}{3^2} + \frac{x^4}{4^2} + \&c.$$

$$\frac{d}{dx} \cdot \left(\frac{ds}{dx} \right) = \frac{1}{1} + \frac{x}{2} + \frac{x^2}{3} + \frac{x^3}{4} + \&c.;$$

$$\therefore \frac{d}{dx} \left\{ x \cdot \frac{d}{dx} \cdot \left(\frac{ds}{dx} \right) \right\} = 1 + x + x^2 + x^3 + x^4 + \&c. = \frac{1}{1-x},$$

$$\therefore x \cdot \frac{d}{dx} \left(\frac{ds}{dx} \right) = \int \frac{dx}{1-x}, \text{ and } \frac{ds}{dx} = \int \frac{dx}{x} \cdot \int \frac{dx}{1-x}$$

Hence, as we have seen in Art. (170.), $\frac{ds}{dx}$, when integrated from $x=0$ to $x=1$, is $= \frac{\pi^2}{6}$.

And

$$s = \int dx \int \frac{dx}{x} \int \frac{dx}{1-x} = x \int \frac{dx}{x} \cdot \int \frac{dx}{1-x} - \int dx \int \frac{dx}{1-x}$$

Now

$$\int dx \int \frac{dx}{1-x} = x \int \frac{dx}{1-x} - \int \frac{x dx}{1-x} = x \int \frac{dx}{1-x} + x - \int \frac{dx}{1-x}$$

$$= x + (1-x) \log(1-x);$$

$$\therefore s = x \int \frac{dx}{x} \int \frac{dx}{1-x} - x - (1-x) \log(1-x),$$

which, integrated from $x=0$ to $x=1$, gives for the sum of the series

$$s = \frac{\pi^2}{6} - 1.$$

These examples will be sufficient to point out the way by which the sum of many other series may be found.

(184.) We here conclude the summation of series, and with it the subject of Finite Differences. Notwithstanding the length to which this Article has run, many things have been but briefly touched on, and some have been omitted.

Among the omissions we must mention the applications of this calculus to geometrical questions. These problems are among the most curious of any that have ever occupied the attention of the analyst, and their perusal will fully reward the labour of the student. But for these and other interesting details connected with Finite Differences we must for the last time refer the reader to the Examples given by Sir J. F. W. Herschell, and finally record our sense of the many obligations we owe to that Work during the preparation of this Article.

The Works too of Laplace and Lacroix, and the Memoirs of Learned Societies, will afford abundant materials for the extension of our knowledge in a subject which appears exhaustless.

Calculus of
Finite
Differences.

CALCULUS OF FUNCTIONS.

CALCULUS OF FUNCTIONS.

Calculus of
Functions.

(1.) To enter into a detail of the applications of the theory of Functions, would be to write a very large Work, as there are few parts of Mathematics into which it has not been carried. This treatise, therefore, confines itself to those matters, which if not considered without reference to application, will not in this period of the Science be considered at all. And by application is meant as well to the ordinary branches of Mathematics as to questions of Physics.

Neither will this Essay embrace all that has been done with the subject, and for the following reasons: those who have invented the little we know on functional equations, little only as compared with the view it gives of the possibility of more, have followed the subject where it led, seizing every relation which presented itself, without inquiring whether the conditions of solution were possible or not. And they were right in so doing, the general interest of the Science being considered; nor do we know whether any benefit would have accrued from deferring to follow out a view which struck them, until any requisite preliminary for complete solution was obtained. But in a work which professes to be so far elementary, that a student who has gone through the usual course of the Differential and Integral Calculus is supposed able to read it, nothing would be less useful than filling an Introduction to the Calculus of Functions with generalities of which particular cases have not been given. That one complicated functional equation has, by a beautiful artifice, been made to depend upon another, of the solution of which there may be more hope, is a matter of great interest, to be recorded for the future inventor, who may thus make two steps in one. But to the student, unless the artifice throw light upon his first principles of notation, or add a general method to his power of combination, such information is secondary. An inventor and an elementary writer stand much in the same relation as an invader and a colonist; the first must seize all he can, the second no more than is useful; the first may go as far as he can make his way, the second no further than he can make a road.

We have, therefore, confined ourselves principally to the elucidation of first principles, and the extension of the ideas which a student must be supposed to have on the subject of notation, together with such methods for the solution of functional equations as have succeeded in giving algebraical results. We have also given such methods of solution as have not yet been reduced to Algebra, in every case wherein we supposed either a useful view might be introduced, or in which we imagined it probable that the next step to be made would be a natural consequence of what has already been done. we have also made such references as will enable the Mathematician to see where may lie the most probable help for any object he may have in view; and this we think enough, considering that there are perhaps in the whole of the Empire not twenty men who are likely to look into a Work of reference with a view to see what has been done in the highest branches of the subject. Even supposing there to be so many, they are already sufficiently familiar with the various Philo-

VOL. II.

sophical Transactions, in which investigators record their results; and to which, as far as we know them, we have referred.

Calculus of
Functions.

Our object will be gained if the student is led to such a knowledge of forms and familiarity with the results of general operations as will render his grasp of ordinary mathematical language more intellectual and less mechanical. The influence of signs on mathematical processes, or, to borrow a term, the etymological branch of Mathematics, is only incidentally a part of the subject-matter of most writings. But, of late years, it has been treated more for its own sake by the following writers,* Babbage, Carnot, Cauchy, Herschel, and Peacock, into whose Works the reader must look if he would judge of the present state of mathematical language.

The very striking differences presented by two functions, which, algebraically speaking, are the same, as will more fully appear in the course of this Essay, sometimes renders the method of drawing general conclusions established in Algebra dangerous, if not altogether unsound. This makes the examination we have given to the manageable cases of functions a matter of some interest to the Mathematician, already sufficiently prepared to find such results by the processes of the Integral Calculus.

We have found it impossible to preserve as much connection as is desirable between the different articles of this Treatise. In a subject hardly yet considered fit for the student, and on which only one *elementary* work exists, of which we have any knowledge, the arrangement which the general methods of the Differential and Integral Calculus enables writers on those subjects to adopt, we soon found to be impossible. More officers must enter the service before functional equations can be drilled into discipline; and while we have, therefore, arranged such materials as we could find or make, in the order in which the student can most easily read, we refer the Mathematician to the general Index at the end.

(2.) By the term *Function* is meant any mathematical expression considered with reference to its form, and not to the value which it derives from giving particular values to the letters contained in it. Thus $a + x$ and $a^2 + x^2$ are both functions of x , but of different forms.

(3.) It is usual to call any expression a function of x only, when it is only with reference to the manner of containing x that it is necessary to consider the function. Thus $a + \log x$ and $b + \log x$ are functions

* See Babbage, in various papers cited in this Work, and his *Elementary Treatise on the Calculus of Functions*; Carnot, *Géométrie de Position*; and *Métaphysique du Calcul infinitésimal*; Cauchy, *Cours d'Analyse*, and *Elémens du Calcul infinitésimal*; Herschel, papers in the *Memoirs of the Analytical Society*, and in the *Philosophical Transactions*, and also his elementary work on the *Calculus of Differences*, and edition of Spence's *Logarithmic Transcendents*; Peacock, *Elements of Algebra*, and *Report on the State of Analysis* in the second volume of the *Memoirs of the British Association*. With the writers of the German School we are not so well acquainted, but if we may judge from such as we have seen, they appear, with the exception of Abel, Jacobi, and Fuss, to have taken a road, which, however useful it may be, does not bring the results of their labours to bear very closely upon the considerations which we have thought it necessary to employ here. The *Calcul des Dérivations* of M. Arbogast, however, has furnished many ideas on the subject.

Calculus of
Functions.

of x of the same form, and so are $\sin px$ and $\sin qx$, (provided a, b, p , and q be independent of x .)

But two functions which are algebraically identical are not therefore of the same form: for instance, $(a+x)(a-x)$ and $a^2 - x^2$, between which algebraical equality always exists, are not of the same form. The processes to which x is subjected in the two are not the same, though the arithmetical result of one set of processes be always the same as that of the other.

(4.) When two expressions contain x and y respectively in such a manner that the substitution of x instead of y changes the first into the second, and *vice versa*, the two are said to be the same functions of x and y . Thus $a - x^2$ is the same function of x which $a - y^2$ is of y . But $a - yx^2$ is not the same function of x which $a - y^3$ is of y ; for though writing y instead of x in the first would give the second, yet writing x instead of y in the second would not give the first.

(5.) Previously to entering upon the symbols peculiar to this branch of Mathematics, it will be useful to look at the nature of the symbols which have preceded. It is usual to say that all symbols are symbols of quantity, and this is true, but only in a sense analogous to that in which $(a+x)(a-x)$ and $a^2 - x^2$ are regarded as identical in Algebra. Considered as representatives of quantity they are the same; not so as representatives of operations. Properly speaking, a symbol of quantity is that in which the connection between the symbol and the quantity is purely arbitrary, without reference to the meaning of any previous symbol, or the result of any defined operation. In Arithmetic, therefore, 1 is the only symbol of quantity: 2 is, in the arithmetic of concrete quantities, the quantity resulting from the operations contained in the symbol $1+1$; in the arithmetic of abstract numbers it is only the representation of the operation $1+1$. For the plainest definition of the science of "Abstract Number" is, the method of reasoning upon the operations which may be performed upon 1, considered independently of the particular quantities which 1 may represent. And Arithmetic itself may be considered as the art of reducing the result of every operation which can be performed upon different functions of 1, to a function of the form

$$a + bx + cx^2 + ex^3 + \&c.$$

where $a, b, c, \&c.$ are severally one or other of the defined symbols 0, 1, 2, 9, x is the operation $9+1$, and generally, pq represents the same function of q which q is of 1. The decimal notation, by which writing is saved, (for in the preceding view every other advantage of it is included,) consists in the substitution of

$$\dots\dots\dots ecba$$

for the preceding series.

(6.) In Algebra (in its most general form) we take as many arbitrary symbols of *quantity* as we please, $a, b, x, \&c.$; understanding also that the symbols may define, as well the magnitude, as any other modification of which concrete quantity admits. But in Algebra, considered as a consequence of *abstract* arithmetic, these are not symbols of quantity, but of undefined, or, *ad libitum*, operations upon 1; having the same indeterminate character with respect to 1, which 1 has with respect to concrete quantity. That is, Algebra is the science which draws conclusions with respect to $a, b, \&c.$, whatever operations they may denote, in the same way as Arithmetic draws conclusions with respect to the definite operations only,

0, 2, &c. whatever concrete magnitudes they may denote. And, strictly speaking, we have in the letters of Algebra our first *arbitrary symbols of operation*.

Calculus of
Functions.

The objects of Algebra are either the determination of the particular characters which $a, b, \&c.$ must have, for the fulfilment of certain conditions, that is, the reduction of problems to equations of condition, and the solutions of these equations; or, the invention of operations which may be substituted instead of given operations, without the alteration of the arithmetical results of any particular case. The latter may be thus stated; *given a function*, and the *form* only of another function, to find the particular case of the form assigned, the results of which shall always be arithmetically* equivalent to the results of the given function.

(7.) But we have yet another case to consider, as follows. Given any number of quantities and any conditions which are to exist between functions of these quantities, required the forms of the functions which will satisfy these conditions. For instance, required that operation which being performed upon x , and again upon the result, shall reproduce x . Of this $a - x$ is a particular case, for if $a - x$ be $p, a - p$, or $a - (a - x)$ is x . Another case is

$$\log(a - \text{No. whose log. is } x)$$

for if this be called p , the repetition of this operation gives

$$\log(a - \text{No. whose log. is } p),$$

$$\text{or, } \log\{a - (a - \text{No. whose log. is } x)\}$$

$$\text{or, } \log(\text{No. whose log. is } x) \quad \text{or } x.$$

We might give more instances, but this will be sufficient to show that as Algebra gives results of greater generality than Arithmetic, so the consideration of the form which will satisfy certain conditions gives results of greater generality than those of common Algebra. The problem enunciated in this article is the general problem of the *Calculus of Functions*.

(8.) Every hint, therefore, which can be gained from the connection of Arithmetic and Algebra, may teach us what to look for, and what to avoid, in the transition from Algebra to the Calculus of Functions. And, first, we must observe, that as the indeterminate character of the algebraical symbols kept out of view the limitations necessary in Arithmetic, so the corresponding character of the symbols to which we shall come, as compared with the definite forms of Algebra, may equally make us lose sight of limitations necessary in the latter science. And as each neglect of the necessary conditions of Arithmetic made algebraical operations more extensive than those of the former Science, the same may happen here.

Though the Calculus of Functions is not yet so far advanced, that we can look back upon such extensions, yet certain anomalies which we shall have occasion to observe oblige us to look forward to them, and we shall therefore now ask, what are these operations of Algebra which have been explained with perfect generality?

The great limitation of pure Arithmetic, namely, that in $a - b$, a must be greater than b , led to the difficulty of negative quantities, since the indeterminate form of a and b prevents the recognition of any such condition. The doctrine of positive and negative quantities, however established, leads to the further difficulty of the square root of

* The word arithmetically is here taken in a very wide sense. It should perhaps be;—Given a function, and the *general* form of another, required (if possible) a *specific* form, such that it and the given function shall be reducible to identity by the same operations.

Calculus of Functions. **Calculus of negative quantity.** The use of $\sqrt{-1}$ (called *impossible*) has of late years pointed out a method of interpretation,* which leaves us finally, we may say, in perfect possession of the following algebraical forms, in which all the letters denote explicit arithmetical quantities, (whole or fractional, rational or irrational.)

$$\pm x, (\pm x)^{\pm y} (+a)^{(\pm y)^n}, \{(-a)^{(\pm y)^n}\}$$

To which we may add the logarithms of the preceding quantities, with their sines, cosines, &c.

But all forms in which the exponent of an exponent has any but a purely numerical form, are not yet, we think, within the dominion of the general theorems of Algebra. For it will appear that such forms may be found to satisfy conditions which common algebraical reasoning would lead us to conclude it impossible to satisfy. And, independently of this subject, it has lately been shown† that the general theorem (or, at least, the observed result) that "all functions which disappear when $x = 0$, can be developed in positive powers of x "

is not true in the case of $e^{-(x)^{-2}}$ or $\frac{1}{x^2}$, which nevertheless vanishes when $x = 0$.

As to definite integrals, the present state of knowledge does not enable us to class them.

We have here no further to do with this subject than to observe at the outset, that, when we prove a case of impossibility by common algebraical reasoning, we mean the impossibility to refer only to those expressions which have been really considered in Algebra, as it now stands. And that, for any thing we know to the contrary, the expressions not yet considered, and *discontinuous* functions in particular, may satisfy an algebraically impossible condition, just as the negative quantity of Algebra satisfies an arithmetically impossible condition.

(9.) The study of Algebra leads to that of variable quantities, in which a letter is considered as assuming all possible values between given limits; and the results of that supposition are traced in the Differential and Integral Calculus. To this we have nothing analogous at present in the Calculus of Functions; we can neither arrange forms in order of magnitude, or according to an order dictated by any other notion which appears necessary to them. It is true that nothing would dispose us to alter the arrangement of the following forms, that is, to change the place of any one in its own set:

a	$\log x.$
$a + bx$	$\log \log x.$
$a + bx + cx^2$	$\log \log \log x.$
&c.	&c.

But suppose we ask, where, in the second series, is the proper place of $a + bx$? We can give no answer, as no place appears more proper than another. But if we write down two sets of algebraical or arithmetical quantities, such as

1	$\frac{3}{2}$	a	$p + q\sqrt{-1}$
2	4	$b + c\sqrt{-1}$	$\sqrt[3]{-1}$
$\frac{1}{2}$	5	$-d$	r
&c.	&c.	&c.	&c.

* See the *Algebra and Report to the British Association* of Mr. Peacock.

† By Professor Hamilton, in a late volume of the *Transactions of the Royal Irish Academy*.

we can, in the first, arrange both sets in an order derived from a notion which we call *comparative magnitude*, which is essential to quantity, meaning that two quantities never present themselves to us unaccompanied by it. And we can immediately remove one out of either set to its proper place in the other. In the algebraical sets, we can do the same in two different ways, answering (as the student acquainted with the theorem

$$a + b\sqrt{-1} = \sqrt{a^2 + b^2} (\sin \theta + \sqrt{-1} \cos \theta)$$

where $\tan \theta = \frac{b}{a}$

will not fail to perceive) to arranging the lines signified by the symbols, in order of inclination or in order of magnitude. But the analogy entirely fails when we take algebraical forms at hazard, or without some specific law of connection; and we therefore propose the following query, which the general results of our future investigations will (in our opinion) incline us to hesitate upon, if not to decide in the affirmative.

May not the Calculus of Functions divide algebraical forms into so many and so distinct varieties, that, judging by the impression remaining on our minds from the differences which have hitherto distinguished *sciences* from one another, we should feel inclined to say that the different classes of functions are rather the objects of different sciences than of different branches of the same science; or, at least, are the objects of branches as different as those which treat of possible and impossible quantities in Algebra?

(10.) But the imperfect considerations connected with functions which physical problems rendered necessary in the Integral Calculus suggested a notion so like what we may conceive to have preceded continuous variation in algebraical quantities, that we do not despair of seeing laws of arrangement established among forms. The notion is that of *discontinuous functions*. When a quantity retains the same value, it is called a *constant*. When a function always retains the same form, no name was ever given to it, no distinction being necessary, because no other case was ever considered. But in the Integral Calculus, it was found that where an arbitrary function, say of x , was introduced in integration, it was allowable to suppose it to have one form for every value of x between a and b , another for every value between b and c , &c. This continuous variation being possible to any extent, we might conceive the limits of invariability diminished without end, so as to present a continuous variation of *form*. We shall afterwards show certain cases in which this is possible, but (remembering that the admissibility of discontinuous functions divided D'Alembert and Euler) we will not undertake to say that a form might be assigned which should satisfy the differential equation; or that if such a form were assigned by one, it would be received as such by another.

(11.) Every new step in the science of symbols has been accompanied by a correlative, usually called the *inverse* step, from whence the first has acquired the name of *direct*. If working with x in a given way produces y , in what way must we work with y to reproduce x ? or, given x , and the way to find y , what is the way to find x when y is given? or, knowing what function y is of x , to find what function x must be of y ? This is properly a question of the Calculus of Functions. Every inverse operation is found to require new modifications of symbols, and, hitherto, every case has pre-

Calculus of
Functions.

sented some difficulties; for it has always been found, that the inverse operation was not generally possible, without some previous extension of the notions necessary to the performance of the direct operation. Thus the first inverse question which presents itself is in Arithmetic, and is the following: if $1 + 1$ be called 2, what is that operation by which 2 may be reconverted into 1? This introduces the notion by which the symbol of quantity itself is considered as a result of operations on certain subordinate symbols of quantity, which would be symbols of pure quantity only, if it were not more consistent with our first ideas to consider the above question as self-evidently answerable, and the inverse operation itself as a new definition resulting from it. But it is to be remarked, that the answer to such questions as the above is not given without the invention of new symbols $\frac{1}{1+1}$, $\frac{1}{1+1+1}$, &c. inverse to $1 + 1$, $1 + 1 + 1$, &c., and an extension of the notion of whole numbers.

The operation of subtraction, the inverse to that of addition, leads to another extension; that of extraction of a root, the inverse of the raising of a power, to another: and so on. And here we observe that every function may have an inverse corresponding to every different quantity which may be considered. If the operation be such as to admit of *interchange*, that is, if the form of a function is the same, whether a or b be considered, the inverses are in both cases of the same form: thus $a + b$ and $a b$, considered with reference to either b or a , give the same inverses. But in a^b , which, considered as a function of a , is not of the same form as when considered as a function of b , there are two inverses, the extraction of a root in the first case, the construction of a logarithm in the second. The following terms are respectively inverse to each other, those which are usually called direct being in the first column:

Addition	Subtraction
Multiplication	Division
Involution	Evolution
Developement	Invelopement*
Exponential	Logarithm
Power	Root
Positive	Negative
Whole number	Fraction
Inversion	Inversion
Reciprocal	Reciprocal
Production	Reproduction
Sine	Inverse sine
Cosine	Inverse cosine
Function	Inverse function
Sum	Difference
Differential	Integral.

(12.) The obvious method of signifying an inverse function would be to invent some abbreviation of the word *inverse*, to be appended to the functional symbol. But it might be equally consistent to take the symbols of any two simple inverse operations we please; and, in whatever sense it may be convenient to connect one of them with the direct functional symbol, in the same

* This term ought to exist; in consequence of the most usual developement being that of a function into the sum of a number of others, the term *summation* usually supplies its place. But in treating of continued products, continued fractions, &c., many awkward circumlocutions are rendered necessary by the want of a general term inverse to developement.

way to connect the other with the inverse functional symbol, so as to make the latter express, both what is the direct operation, and what is the inverse. The following will explain our meaning.

If we consider the series of quantities

$$1, 2, 3, 4, 5, \&c.$$

as being each formed from the preceding by the same general operation, and the same particular case of it, it is evident that the operation is $+1$, or any term being p , the next term is $p + 1$. The inverse of this operation is -1 , and we thus get the series of direct and inverse terms,

$$\dots -2 \quad -1 \quad 0 \quad +1 \quad +2 \quad \dots$$

We may, by extension of our language, say that we here consider the natural numbers as functions of 0, for since it is the definition of an inverse function that the direct operation performed upon it produces the *subject** of the function, and since $-a + a$ is always $= 0$, we must, if we make any such extension at all, when we consider $-a$ as an inverse of a , say that a is considered as a function of 0.

We may also say that the *modus operandi* is absolute, the formation of each from its predecessor having no reference to the place of the latter.

(13.) We may now ask, having got this notion, how are the series of natural numbers to be considered as functions of 1. That is, what direct operation performed upon its inverse always produces 1? The answer is

$\left(\frac{1}{a}\right) \times a = 1$, and the series of direct results being 1, 2, 3, &c. as before, the series of inverse results is $\frac{1}{2}, \frac{1}{3}, \frac{1}{4}$, &c., or we get

$$\dots \frac{1}{3}, \frac{1}{2}, 1, 2, 3, \dots$$

We, therefore, see reason to change the imperfect analogies of article (5.) and to consider 0 as there the symbol first operated on, and $+1$ as the *modus operandi* by which x becomes $x + 1$: but when we consider

$x \times \frac{x+1}{x}$ is the *modus operandi*, then 1 is the

symbol first operated on. And here the *modus operandi* is relative, the formation of each number from its predecessor being directly dependent upon the latter.

We may now ask, according to what method of derivation may all numbers be considered as functions of 2. What direct function performed upon its inverse will

always produce 2? Since $(2^x)^{\frac{1}{x}} = 2$, the series of direct quantities 2, 3, 4, may be (λa representing the logarithm of a to the base 2)

$$2^{\lambda 2}, 2^{\lambda 3}, 2^{\lambda 4}, \&c., \text{ or } 2, 3, 4, \&c.;$$

and the inverse set is $2^{\frac{1}{\lambda 2}}, 2^{\frac{1}{\lambda 3}}, 2^{\frac{1}{\lambda 4}}$, &c. the first of which, being $= 2^{\lambda 2}$, (giving 2, which coincides with 0 and 1 of the preceding cases in being its own inverse, and which we shall therefore not distinguish,) may be considered as the first of the previous set and the complete set is

$$\dots 2^{\frac{1}{\lambda 4}}, 2^{\frac{1}{\lambda 3}}, \left(2^{\frac{1}{\lambda 2}} = 2^{\lambda 2}\right), 2^{\lambda 3}, 2^{\lambda 4}, \dots$$

* When a function of x is mentioned, x is the *subject* of the operations.

Calculus of
Functions.

Calculus of
Functions.

We might propose an infinite number of other ways in which the series of natural numbers might be considered as functions of any one among them: but the above will be sufficient to illustrate this point, that each set gives a distinct set of inverses, and that we have therefore an unlimited number of methods by which we may represent inverse functions of different species, choosing of course those methods which present any analogy to the manner of deriving the inverse in question. We shall return to this subject.

(14.) We now proceed to explain the notation of functional symbols. As in Arithmetic the notion of concrete quantity was generalized into that of abstract number, and in Algebra *definite* abstract number was abandoned for symbols of general number, thus enabling us to express any *definite* operation performed with an indefinite number, so in the Calculus of Functions the definite character of the operation is dropped, and indefinite symbols of operation are used, which may be either *unknown*, to be found by means of conditions, or *arbitrary*, to be assigned at pleasure, or *conventionally definite*, (like π and e in Algebra,) to denote particular operations which frequently occur. The symbols usually employed are the letters $F, f, \phi, \psi, a, \beta$: but in the present Treatise *all Greek letters are functional symbols except π and e* , (ω is a functional symbol,) and of the small Roman letters, f only is a functional symbol. And no letter which is a functional symbol in any one place will be used as a symbol of quantity in any other.

The subject of the function is written after or under the functional symbol, as may be most convenient. Thus ϕx or ϕ_x means some operation to be performed upon x : and

$$F x, f x, \phi x, \psi x, \chi x, a x, \beta x,$$

may all denote the results of different operations performed on x , or different functions of x . And when two functional symbols are placed before x , as in $\phi \psi x$, it is meant that the operation ψ having been performed upon x , the operation ϕ is to be performed upon the result. Each functional symbol has a permanence of meaning throughout the same problem.

The symbols of unknown functions will usually be ϕ, ψ , and χ ; those of given functions, a, β , &c., those of arbitrary functions $\theta, \rho, \sigma, \tau$; the symbol λ will always stand for the Napierian logarithm, and $\sin, \cos$, &c. for sine and cosine, &c., as in Trigonometry.

The following examples will illustrate this notation.

1. Let $\phi x = a^x$; then $\phi(x+1) = a^{x+1}$, $\phi \lambda x = a^{x^x}$ $= e^{x \log x}$ $= x^{x^x}$; $\phi(\sqrt{-1}x) = a^{\sqrt{-1}x}$; $\phi \sin x = a^{\sin x}$.

2. Let $\phi x = 1+x$; then $\phi \phi x = 1 + \phi x = 1 + (1+x) = 2+x$; $\phi \phi \phi x = 1 + \phi \phi x = 3+x$,

and so on. Let $\phi x = a^x$; then $\phi \phi x = a^{\phi x} = a^{a^x}$, &c.

3. Let $\phi x = \cos x$, $\psi x = x^2$; then $\phi \psi x = \cos(x^2)$ $\psi \phi x = (\cos x)^2$.

$$\text{Let } \phi x = \frac{1+x}{1-x} \quad \psi x = \frac{1-x}{1+x}$$

$$\phi \psi x = \frac{1 + \frac{1-x}{1+x}}{1 - \frac{1-x}{1+x}} = \frac{1}{x}$$

$$\psi \phi x = \frac{1 - \frac{1+x}{1-x}}{1 + \frac{1+x}{1-x}} = -x.$$

4. What function of x is that which being multiplied by itself gives an equivalent to a second result of the same functional operation? The functional equation from which the form of ϕ is to be found, is evidently $(\phi x)^2 = \phi \phi x$. One solution is evidently $\phi x = x^2$. What function is that which is not changed in value by writing $x+1$ for x ? The functional equation is $\phi(x+1) = \phi x$.

(15.) When an operation is to be performed a number of times in succession upon the same quantity and its results, the symbols $\phi \phi x$, $\phi \phi \phi x$, &c. are abbreviated into $\phi^2 x$, $\phi^3 x$, &c. in which it must be recollected that ϕ being a symbol of operation, the index stands for the number of times the operation is repeated. Thus the question in (7.) was as follows; required solutions of $\phi^2 x = x$.

Thus $\lambda^2 x$ means the logarithm of the logarithm of x , which call the second logarithm of x ; $\sin^2 x$ means the sine of the sine of x ,* the common meaning, the square of the sine of x , being, in this subject, rejected for the preservation of symmetry. The latter is denoted by $(\sin x)^2$, meaning $\sin x \times \sin x$.

(16.) There are two species of inversions to which we shall appropriate distinct symbols. The first, which has more reference to Algebra, (in which the investigation of it in different cases continually occurs,) I shall call the *algebraical* inverse, or simply the inverse, this particular one being understood whenever the single word occurs. But the second, the idea of which will now be met with by the student for the first time, I call the *functional* inverse, never dropping the first word.

If $\phi x = y$, then x is also some function of y , as in the following instance:

$$y = (x-1)^2, \quad x = 1 + \sqrt{y}; \text{ or } x = 1 - \sqrt{y};$$

so that if $x = \psi y$, one form of ψy is $1 + \sqrt{y}$, and one form of ψx is $1 + \sqrt{x}$. This is an *algebraical* inverse of $(x-1)^2$.

Again, suppose we repeat any function any number of times, say that ϕx being $a x$, we find $\phi^2 x$, which is $a(a x)$ or $a^2 x$. The algebraical inverse of this

function is $\frac{x}{a^2}$. In this method we observe that there is no reference to the accumulated operations by which $a^2 x$ was supposed to have been obtained; the inverse is the same, whether we consider $a^2 x$ as our primitive function, or whether we regard it as the third function of $a x$. If we look at the series of direct and inverse quantities

$$-3, -2, -1, 0, +1, +2, +3, \&c.$$

we perceive an analogy. When we here form one from the preceding, the *modus operandi* has no reference to the number of steps by which that predecessor was formed from 0. We shall, therefore, choose these inverses $-1, -2$, &c. as convenient indices of the algebraical inverses of ϕx , $\phi^2 x$, &c. That is, $\phi^{-1} x$ shall be the algebraical inverse of ϕx , (or, by analogy, $\phi^1 x$), $\phi^{-2} x$ of $\phi^2 x$, &c. So that if $\phi x = y$, $x = \phi^{-1} y$; if $\phi^2 x = y$, $x = \phi^{-2} y$, &c. Generally $\phi^{-n} x$ means that

* It must be remembered that the angle of analysis is measured by the abstract number which expresses the ratio of any subtending arc to its radius. Thus the angle 1 (or the angle whose arc = radius) is in degrees $57^\circ 17'$ nearly: its sine is .84135, which, considered as an angle, is equivalent to $48^\circ 18'$, whose sine is .7466 nearly; so that

$$\sin^2 1 = .7466 \text{ nearly.}$$

Calculus of
Functions.

Calculus of Functions. operation upon which if ϕ be repeated n times, the result shall be x , which by analogy from the series is $\phi^0 x$. The operation ϕ^2 performed upon $\phi^{-2} x$ restores x , or $\phi^2 \phi^{-2} x = x$. But we may ask this question; if $\phi^2 x$ be not considered as absolute, but as dependent upon x , or as a function of x , that is, if $\phi^2 x = \psi x$, what is the connection of the operations ϕ and ψ ? To take an instance; let $\phi x = ax$, $\phi^2 x = a^2 x$, or $\psi x = a^2 x$.

Here $a^{\frac{1}{2}} x$ stands to ax and $a^2 x$ in this inverse relation, that whereas $a^2 x$ is the second function of x , when ax

is the first, $a^{\frac{1}{2}} x$ is the first function to which ax is the second. This is what we call the second functional inverse, and it bears relation to the number of operations by which the direct function was obtained. Hence, by a similar analogy, we shall choose the inverses of the set

$$\dots\dots \frac{1}{3}, \frac{1}{2}, 1, 2, 3 \dots\dots$$

to represent these functional inverses, that is, since ψ is ϕ^2 , ϕ shall be $\psi^{\frac{1}{2}}$. And we have the following relation

in the particular case in question, $\psi^{\frac{1}{2}} \psi^{\frac{1}{2}} x = ax$, or $(\psi^{\frac{1}{2}})^2 x = ax = \phi x$.

If we ask what five similar operations performed on x will produce the same result as ϕ performed twice, or what must ψ be that $\psi^5 x = \phi^2 x$, by the same analogy we call $\phi x = \psi^{\frac{2}{5}} x$ and $\psi x = \phi^{\frac{5}{2}} x$, or generally $\psi^{\frac{m}{n}}$ indicates that operation, which being performed n times, shall produce ψ^m .

(17.) We may now show that the extensions of language in (12.) and (13.) may be made to accord with the notions just laid down. If $\phi x = x + 1$, we have $\phi^2 x = \phi x + 1 = x + 2$, and $\phi^n x = x + n$. If we suppose $x = 0$ this gives

$$\left. \begin{array}{l} x \text{ or } \phi^0 x = 0 \\ \phi^1 x = 1 \\ \phi^2 x = 2 \\ \&c. \quad \&c. \end{array} \right\} \begin{array}{l} \text{in the case} \\ \text{where } x = 0, \end{array}$$

and we find the preceding equation to hold good when n is negative. For if we assume

$$\begin{array}{l} \phi^{-2} x = x - 2 \\ \text{then } \phi \phi^{-2} x = \phi^{-2} x + 1 = x - 1 \\ \text{and } \phi^2 \phi^{-2} x = \phi \phi^{-2} x + 1 = x. \end{array}$$

But as it is not the custom to consider functions of particular values of x , we shall say the natural numbers are the successive functions of $x + 1$ when $x = 0$.

The consideration of the successive numbers as functions of 1 is somewhat more refined. If we consider the function ax , we have $\phi^2 x = a(ax) = a^2 x$ and $\phi^n x = a^n x$, giving us

$$\left. \begin{array}{l} \phi^0 x = 1 \\ \phi^1 x = a \\ \phi^2 x = a^2 \\ \phi^3 x = a^3 \\ \&c. \quad \&c. \end{array} \right\} \begin{array}{l} \text{in the particular case} \\ \text{where } x = 1. \end{array}$$

Now we cannot, for any value of a , find the series of natural numbers in the set $1, a, a^2, \&c.$ But by taking a sufficiently near to unity, we may so manage, that all the numbers under a given limit (say a million) shall severally be as near as we please to one or other of the powers of a (say within .000001.) Or, if we express

Calculus of Functions. this theorem in the language of Leibnitz, we should say that if a be infinitely near to unity, some powers of a , $a^{m_1}, a^{m_2}, a^{m_3}$, with infinite exponents, having finite ratios to one another, will be severally equal to 2, 3, 4, &c. In this sense, then, we may say that $(1 + a)x$, where a is infinitely small, is the function which gives the scale of numbers when $x = 1$, but that the successive numbers are not successively produced, there being an infinite number of operations interpolated between each.

When we see quantity in a state of continuous increase, we are so accustomed to consider the increase as absolute, that we admit the notion of a succession of infinitely small and equal increments in infinitely small and equal times, without much repugnance. But because the proportion or the rate of increase is rather harder, we do not so readily admit the notion of quantity increasing at an infinitely small rate per cent. in successive infinitely small times. But we see that the second is the necessary consequence of supposing numbers to be, in our phrase, functions of x , where $x = 1$, instead of functions of x , where $x = 0$.

The preceding view is sufficiently practical, or was, for by it Napier constructed logarithms before exponents were used.* Halley's words in the preceding note, that he considers ratio as a "quantity *sui generis*," correspond to what is meant by saying numbers are functions of 1.

In a similar way, by considering a as infinitely small, we might have supposed any number or fraction to be an n^{th} function of ϕx or $x + a$ in the case where $x = 0$.

(18.) Next to the symbols of quantity in importance come those of the calculus of differences, whether finite or infinitely small, such as $\Delta, d, \Sigma, \int, \&c.$ These are certainly not symbols of quantity, but of operation, and

* This ought to be more prominently stated in elementary Works, as one of the greatest curiosities in the History of Science. We remember discussing the merit of the invention with a friend, when both of us were students at Cambridge, the one for, and the other against, both being under the impression that the system flowed naturally from the extended exponential symbol, and neither (as might be supposed) being Historian enough to know the contrary. Napier published his *Mirifici Logarithmorum Canonis* &c., in 1614, and even in the time of Halley the symbols of Algebra were insufficient to furnish a theory. The ideas of the latter we quote: "Logarithms may be properly said to be *numeri rationum exponentes*; wherein we consider ratio as a *quantitas sui generis*, beginning from the ratio of equality, or 1 to 1 = 0; and these ratios we suppose to be measured by the number of *rationunculae* contained in each. Now these *rationunculae* are so to be understood as in a continued scale of proportionals infinite in number between the two terms of the ratio, which infinite number of mean proportionals is to that infinite number of the like and equal *rationunculae*, between any other two terms, as the logarithm of the one ratio is to the logarithm of the other. Wherefore, if the root of any infinite power be extracted out of any number, the *differentiola* of the said root from unity shall be as the logarithm of that number." *Misc. Cur.* vol. ii. p. 38, 39. Halley, of course, had whole exponents, and even fractional ones, and thus was within (one would think) a hair's breadth of the simple definition, "if $y = a^x$, x is the

logarithm of y ." In this very paper he used $(1 + q)^{\frac{1}{m}}$ not expressly as the m^{th} root, but as an abbreviation of Newton's development. On such small matters of symbolic notation do the simplifications of analysis depend, that the Calculus of Functions assumes a character of importance. And, unfortunately, improvements in symbols travel more slowly than any others. Perhaps the abolition of the fluxional notation in England is not in point, as national prejudice interfered: but when was the decimal point (certainly used by Napier) finally introduced into schools and colleges in France? We have evidence before us that it was after 1710, and perhaps long after, and also that the Ptolemaic system was taught as the most probable at the same time.

yet are not strictly *functional* symbols, in the sense in which we have to consider functions. As nothing is of more consequence in this Science than to avoid letting the reader fall, for want of warning, into a notion that the definitions of ϕ , ψ , &c., and their consequences,

have any necessary affinity with those of Δ , $\frac{d}{dx}$, &c.

and their consequences, we shall examine the degree of connection which exists between the two.

It is plain that Δu_x or $u_{x+h} - u_x$ may always be considered as a function of u_x ; that is, * *dependent upon x through u_x only*. For if $u_x = p$, from which x may be found in terms of p , and substituted in $u_{x+h} - u_x$, the result is a function of p only. To take two instances,

$$u_x = \sin x \quad \Delta u_x = u_x \cos h + \sqrt{1 - u_x^2} \sin h - u_x,$$

$$u_x = x^2 \quad \Delta u_x = 2h\sqrt{u_x} + h^2.$$

Consequently, $\Delta \phi x$ is a function in which the functional nature of Δ depends upon that of ϕ . But in $\psi \phi x$, ψ is considered merely as the index of certain operations to be performed, not on the form of ϕ , but on ϕx considered as a result. Thus if $\psi x = x + x^2$, we have

$$\psi \phi x = \phi x + (\phi x)^2 \quad \psi e^x = e^x + (e^x)^2$$

$$\psi(x + \chi x) = x + \chi x + (x + \chi x)^2$$

$$\psi a \beta \gamma x = a \beta \gamma x + (a \beta \gamma x)^2;$$

or $\psi \phi x$ performs the same operations on ϕx , which $\psi a \beta \gamma x$ does on $a \beta \gamma x$. But $\Delta \sin x$ does not perform the same operation on $\sin x$ which Δx^2 does on x^2 . In fact, we may see that though the very simple nature of the connection between Δu_x and u_x , expressed by

$$\Delta u_x = u_{x+h} - u_x$$

renders the operations easy, yet that in principle we have, by the definition of Δ , ascended one step higher than the Calculus of Functions in the scale of generalization, by which concrete Arithmetic became abstract, abstract Arithmetic Algebra, and Algebra the Calculus of Functions. For we have thus proposed operations upon the form of ϕx , that is, Δ (if $\Delta \phi x$ be considered as a function of ϕx) stands to ϕ in the same relation as ϕ to x , or as x to abstract, or as abstract to concrete quantity.

But there is another point of view (and that, it may be, the more natural one) in which $\Delta \phi x$ is not considered with respect to ϕx , but with respect to x . If we arrange quantities in an order dictated by any law whatever

$$\dots a_{-3} a_{-2} a_{-1} a_0 a_1 a_2 a_3 \dots$$

and consider $+ \Delta u_x$ as the operation by which we pass from u_x to u_{x+1} , it is clear that we have a perfect analogy with the contents of (12.) If we consider that in the symbol $+ \Delta u_x$, the u_x is merely inserted to recall to the mind at what point of the series we suppose ourselves to be, we shall see that $u_x + \Delta u_x$ has a connection with $(1 + \Delta)u_x$, of the same kind as $a + ba$ with $(1 + b)a$; a being considered as the result of an operation on 1,

* This phrase we have often found necessary: its meaning is as follows. If y be a function of x , then ϕy is also a function of x , but only because y is so. Therefore, we say, ϕy is a function of x , *through y* . Thus $x^2 + 2xz + z^2$ is a function of x and of z through $x + z$; if the latter equal y , the function is y^2 , not containing x or z . But $x^2 + 2xz$, though it may be considered as a function of either x or z , through $x + z$, cannot be thus considered as a function of both; for if $x + z = y$, $x^2 + 2xz$ must be either a function of y and x , or of y and z . One of the two, x and z , being eliminated, the other remains.

and $(1 + b)a$ being the same operation on a which $1 + b$ is on 1. Still more direct is the analogy of $u_x + \Delta u_x$ and $(1 + \Delta)u_x$ with 7 pebbles + 3 pebbles and $(7 + 3)$ pebbles. Considered in this light, the Calculus of Differences is (whichever word may be deemed most correct) a refinement, extension, or generalization of the method of figures, "the only true demonstrable root of human knowledge."

(19.) The preceding view may perhaps remove some of the feeling of unmixed astonishment with which the student always regards (or ought to regard) the now common method of the *separation of the symbols of operation from those of quantity* in the higher Mathematics. Lagrange's well known theorem

$$(1 + \Delta)^n u_x = u_x + n \Delta u_x + n \frac{n-1}{2} \Delta^2 u_x + \dots \text{&c. (A),}$$

the truth of which may be easily established, *treats* (not considers) Δ as a quantity on the first side, and as a symbol of operation on the second. And so, in an enlarged view of Algebra, does

$$(1 + a)^n b = b + n a b + n \frac{n-1}{2} a^2 b + \dots \text{&c. (B)}$$

as explained in (5.) The connection was necessary to Halley, in explaining logarithms without* the direct aid of exponents.

In his version of the preceding theorem, b was omitted, and $(1 + a)^n$ was a *quantitas sui generis*; even the meaning of numerical symbols had been altered, and 0 merely meant "ratio of one to one."

(20.) It would not be difficult so to generalize the notion of successive counting, that Algebra should become a Science of operations, even in the higher sense in which Δ , an operation, is distinguished from u_x , a quantity. By that method, (B) would become a particular case of (A) in which u_x is derived from the equation $\Delta u_x = b u_x$. And Laplace's theory of generating functions might easily be connected with such a system.

(21.) The Calculus of Ratios, for so it should be called, really exists, though for convenience logarithmically connected with that of differences. From analogy with (13.), we might express the method of passing from term to term of the series in (18.) by $\times \nabla u_x$, in which case $u_{x+1} = u_x \nabla u_x$. But as, if $v_x = \lambda u_x$, we have

$$\Delta v_x = \lambda \nabla u_x, \text{ or } \nabla u_x = \epsilon^{\Delta v_x},$$

the theorems of the second Science are virtually deducible from certain cognate theorems of the first. But the study of the consequences of defining

$$\nabla u_x \text{ to be } \phi(u_x, u_{x+1}, \dots, u_{x+n})$$

is yet in the merest infancy.

(22.) If we proceed to apply the preceding notions to the Calculus of Functions, we are stopped by a warning from the method by which Arithmetic was made Algebra. The nature of the extension by which we passed from $u_x + \Delta u_x$ to $(1 + \Delta)u_x$ required no apparent extension of the usage of the sign $+$, which continued to signify algebraical addition.

But, in the same manner as in Algebra, the sign $+$ acquired an extended meaning in the formula $a + \sqrt{-1}b$, or $a + (-b)$, so it may happen that the most

* We mean that his exponents were simply abbreviations of subsequent algebraical operations, not employed in his definition or theory of logarithms.

Calculus of Functions.
 general algebraical meaning of $+$ will not render those theorems true of $(\phi + \psi)x$, considered as meaning $\phi x + \psi x$, which are true of $(a + b)x$ where a and b are quantities.

The first enquiry in Algebra appears to be, how to invent a simple and consistent notation, and deduce rules from it. But this soon gives place to an inverse enquiry, namely, how to invent notation, so that the rules which follow from it shall be simple and analogous to those which have preceded. We might, if we pleased, say, let $(\phi + \psi)x$ mean $\phi x + \psi x$, in which case $(\phi + \psi)^2 x$ must stand for the same function of $\phi x + \psi x$, which the latter is of x , or for

$$\phi(\phi x + \psi x) + \psi(\phi x + \psi x).$$

But this definition would be of no use, so far as its connection with previous results is concerned, unless we

$$\begin{aligned}\phi^2 x &= a \{a(x+m) - m + m\} - m = a^2(x+m) - m, \\ \phi \psi x &= a \{b(x+m) - m + m\} - m = ab(x+m) - m = \psi \phi x, \\ \phi x + \psi x + m &= (a+b)(x+m) - m = (\phi + \psi)x, \text{ by definition,} \\ (\phi + \psi)^2 x &= (a+b)^2(x+m) - m, \\ &= \phi^2 x + 2\phi \psi x + \psi^2 x + 3m.\end{aligned}$$

But, by the same rule, which laid down that

$$(\phi + \psi)x \text{ means } \phi x + \psi x + m,$$

we have

$$\begin{aligned}(\phi^2 + \phi \psi)x &= \phi^2 x + \phi \psi x + m, \\ (\phi^2 + \phi \psi + \phi \psi)x &= \phi^2 x + 2\phi \psi x + 2m, \\ (\phi^2 + 2\phi \psi + \psi^2)x &= \phi^2 x + 2\phi \psi x + \psi^2 x + 3m.\end{aligned}$$

Hence it appears that the separation of the symbols of operation and quantity can (for these functions) be carried to the same extent at least as in the Calculus of Differences, with this extension of meaning of the sign $+$; that $+$ placed between two isolated signs of operation, each taken once, requires the addition of m when the symbols of operation are reconnected with their symbols of quantity; or, that if

$$\phi_1 x = a_1(x+m) - m,$$

$$\phi_2 x = a_2(x+m) - m,$$

$$\dots \dots \dots$$

$$\phi_n x = a_n(x+m) - m,$$

$$(p_1 \phi_1 + p_2 \phi_2 + \dots)x \text{ means } p_1 \phi_1 x + p_2 \phi_2 x + \dots + (p_1 + p_2 + \dots - 1)m.$$

Hence $(\phi - \psi)x$ means $\phi x - \psi x + (1 - 1 - 1)m$, or $\phi x - \psi x - m$.

The inverse of $a(x+m) - m$ is $\frac{1}{a}(x+m) - m$;

or if $\phi x = a(x+m) - m$,

$$\phi^{-1}x, \text{ by analogy } \frac{1}{\phi}x, \text{ is } \frac{1}{a}(x+m) - m;$$

whence $\psi \frac{1}{\phi}x$, by analogy $\frac{\psi}{\phi}x$, is $\frac{b}{a}(x+m) - m$,

and $\left(\frac{\psi}{\phi}\right)^2 x$, considered merely as a repetition of the

operation $\frac{\psi}{\phi}$, is $\frac{b^2}{a^2}(x+m) - m$: but considered as $\psi^2 \phi^{-2}$,

or as the operation ψ twice repeated upon the second

algebraical inverse of ϕ , which is $\frac{1}{a^2}(x+m) - m$,

it gives, as might be expected, the same result.

Similarly, $(1 + \psi)x$ will be $x + \psi x + m$, or

could deduce relations between ϕx , ψx , and $(\phi + \psi)^2 x$, similar to those which exist between ax , bx , and $(a+b)^2 x$: for instance, our definition will be useless unless $\phi \psi x = \psi \phi x$, and

$$(\phi + \psi)^2 x = (\phi^2 + 2\phi \psi + \psi^2)x.$$

If $\phi x = ax$ and $\psi x = bx$, the above equation is true, but this is nothing more than calling a coefficient an operation instead of a quantity. But there may be more complicated cases, in which the indifference of the symbols of operation and quantity may be established. For instance, let

$$\phi x = a(x+m) - m \quad \psi x = b(x+m) - m.$$

Here, if $(\phi + \psi)x$ stand for $\phi x + \psi x + m$, we have the following:

$(a+1)(x+m) - m$ and x must be considered as $\phi_1 x$, when $a_1 = 1$;

$$\begin{aligned}(\epsilon^{\psi})x &= \left(1 + y\psi + \frac{y^2}{2}\psi^2 + \dots\right)x \\ &= x + y\psi x + \frac{y^2}{2}\psi^2 x + \dots + (\epsilon^y - 1)m\end{aligned}$$

$$\begin{aligned}\lambda \overline{1 + y\psi}x &= \left(y\psi - \frac{y^2}{2}\psi^2 + \frac{y^3}{3}\psi^3 - \dots\right)x \\ &= y\psi x - \frac{y^2}{2}\psi^2 x + \dots + \{\lambda(1+y) - 1\}m;\end{aligned}$$

or rather the second sides must analogically be considered as operations on x , represented by ϵ^{ψ} and $\lambda \overline{1 + y\psi}$, considered as functional symbols. And thus a meaning may be given to ϕ^y considered as a functional symbol.

(23.) But in the greater number of cases which might be proposed, analysis does not yet furnish the means of assigning how $+$ and $-$ between symbols of operation may be defined, so that $(\phi + \psi)^2 x$ and $(\phi^2 + 2\phi \psi + \psi^2)x$ may have the same meaning, &c. And this even in the case of functions which appear altogether congruous, such as $ax + b$ and $px + q$. One case more, however, is virtually contained in the theory of logarithms. If $\phi x = x^m$ and $\psi x = x^n$, the functional symbols may be treated as quantities, provided $(\phi + \psi)x$ mean $\phi x \times \psi x$, &c. For in that case $(\phi + \psi)x$ means x^{m+n} , and $(\phi + \psi)^2 x$ means $x^{(m+n)^2}$, and $(\phi^2 + 2\phi \psi + \psi^2)x$ means $\phi^2 x \times 2\phi \psi x \times \psi^2 x$, or $x^{m^2 + 2mn + n^2}$, which agrees with the former. And from the case in the last article, and the present, we may use the symbols of operation as quantities, provided the

functions are all of the form $\frac{(mx)^a}{m}$, where m is the same

in every case, and where $(\phi + \psi)x$ denotes $m \times \phi x \times \psi x$, &c.

But suppose we ask, what relation exists between the logarithm and the sine, so as to establish any connection between the second logarithm and sine, the sine of the logarithm and the logarithm of the sine, and to simplify operations upon these functions by constituting

Calculus of Functions. $(\log + \sin) x$ a defined operation. What meaning will it here be convenient to give to $+$? This question we have not the most remote means of answering.

(24.) The last two articles open a wide field of speculation upon the possible limits of analysis. Looking at common Algebra merely to pick out the leading features of its notation, we observe two sets of inverse operations; the first $+$ and $-$, the second $\times$ and $\div$, so connected with the first, that from them follows a primary branch of Mathematics, called the theory of logarithms, which is properly the theory of the connection between the first set of operations and the second. But suppose it had so happened that the construction of our reasoning faculties had made some one of the thousand lights in which Multiplication and Division might be viewed more simple than that of their derivation from Addition and Subtraction. We think there is ground to argue that this might have been in some degree the case with the Greek geometers and their successors; at any rate the general supposition is possible, for any thing we know to the contrary. Addition and Subtraction would then have been performed by an inverse method of logarithms; the numbers would have been arranged in geometrical instead of arithmetical series; the ratios which are incommensurable (that is, not expressible in the way we think most simple) might have been commensurable, and *vice versa*. Suppose, for instance, that the series of powers of 2 had been pointed out as the scale of *natural*

numbers. Then $2^{\frac{1}{2}}$, $2^{\frac{1}{3}}$, &c. would have stood (as to simplicity) in the light of fractions, 3 would have been an incommensurable fraction, and $2 + 3$ (if ever it were discovered) a very difficult operation.

Similarly, if it had so happened that $a(x + m) - m$ had been more easily tabulated, either on paper or in memory, than what we call a product, it would itself have been denoted by ax , or, as we have called it, ϕx ; and the product which we now call ax would have been considered under another form, perhaps as $\phi(x + 1) - \phi(1)$.

(25.) The Calculus of Functions, therefore, may be looked at in the following light, when considered in its most general form. Granting any given forms of operation, ϕx , x , &c., as fundamental, required the translation into our notions of the most simple relations, and *vice versa*: also, what must the fundamental operations be, in order that certain modes of connection (according to our views) may exist between them. The use of such questions must be obvious to those who consider how apt we are to take the conventions derived from our own* first view of numbers as the limits of our method of considering symbols. "Addition and Subtraction must be the most simple mode of considering magnitudes, it is in the nature of things," says many a mental philosopher. It is worth while to see how far another nature can be given to things, (if the words of an unintelligible phrase are to be considered as having sepa-

* Many other points of speculation might be added, all tending to disembarass the mind of false connections between symbols and reasoning, or phenomena and reasoning. If all mankind had spoken one language, in what light would the possibility of different languages have been viewed? If the rays of light had not moved in straight lines, what would have been the effect on our notions of figure? Would the straight line in that case have been the one to which all other lines would have been referred? &c. &c.

To the student of mathematical symbols we should decidedly recommend attention to the methods by which the deaf and dumb are taught to read and write.

rate meaning,) and to recollect that, as every extension of notation has, by laying down new operations as fundamental, assumed the possession of certain new powers, and that the mathematical sciences seem to have slackened their progress during the present century, the relations of symbols are worth looking at as modes of invention. It is not a bold surmise, that any great step in the Mathematics can only be made by observing some new relations existing between forms, and assuming the value of these forms to be known in all cases, an assumption which is rendered a truth by placing them in tables. Thus sines, logarithms, elliptic integrals, values of $\int e^{-t^2} dt$, &c., have been successively tabulated, and put in the light of assumed operations.

(26.) Two more warnings may be obtained from algebraical recollections. The first, not to be hasty in proposing new symbols of notation, but to wait until theorems point out consequences to which it will be convenient to adapt notation. And here we mean particularly compound notation: that is, it must be immaterial whether ξ or ρ stand for an arbitrary function; but it may be dangerous to the progress of the Science to assume that ξ_2 and ρ_2 stand for operations which have some specific connection with ξ and ρ , unless the convenience of that connection appear in the methods which made ξ and ρ necessary. The student who endeavours to apply principles must immediately become an inventor of notation, and much of his success must depend upon whether he does this well or not. He must abstain from generality in symbols, unless where there is generality in the theorems which can be immediately connected with them. By inventing a shorter method of writing, he is almost sure to lose sight of some relation, unless his new notation* *only abbreviates, and does not abolish*. So far as it ceases to suggest, it becomes no notation at all. This remark is particularly necessary in treating the Calculus of Functions, because much notation is used which is not abbreviation. But what is rejected is not done for the sake of abbreviation, but purposely to throw away all that the rejected notation would suggest. If the student carries this process much further, he will never find his mistake, simply because he will never have clear ideas on the subject.

Symmetry of notation is indispensable in all complicated processes. There is a limit at which the mind requires a dictionary, if the similar relations between different sets of symbols be not suggested by some similarity of character in the notation. Symmetry begets symmetry, and an unsymmetrical result from symmetrical data is almost a proof of error, while the contrary is a presumption of truth. For it is very unlikely that error should not affect this point.

(27.) The second caution is as follows. When, in Algebra, a particular case requires that some term or terms of a general theorem become evanescent, nothing or zero, whichever it may be called, some peculiarity of form is generally observed. As the zero of quantity is that which is conceived neither to increase nor diminish quantity, so we shall term the zero of operation that which is conceived to make no alteration in the subject of a function, and which is denoted by ϕ^0 . Thus $\phi^0 x = x$,

* Some writers carry this so far, that they hardly leave more than one form of equation, $U = 0$, in the whole of Mathematics

Calculus of
Functions.

meaning that if we ask what function of x will fulfil certain conditions, and the answer is $\phi^0 x$, we know that x itself is the answer desired, and x , considered as a function of itself, we may say is operated upon by the zero of operation, that is, not changed at all. Observe, then, that wherever we make a supposition which destroys a real operation, we substitute ϕ^0 for ϕ , and may find among our symbols effects analogous to those produced by making $x = 0$ in Algebra. For instance, if $c \phi x$ be a term of an equation, of which we have the general solution, we must not hastily conclude that the general solution will apply when $c = 1$; for by this supposition we substitute an operation which does not change value for one which does. We are more likely to find the general solution apply to the case where $c = 0$, because $0 \times \phi x$ is an operation which does change ϕx ; though in the latter case we must remember that we have all the possibilities of common Algebra to encounter. Again, in a general solution, with respect to $\phi x + c$, we may safely, functionally speaking, suppose $c = 1$, though we are now not sure what may result from $c = 0$.

We have no reason to assume that expressions which resemble each other algebraically, are the same in their functional properties. Thus $\frac{2+2x}{6-2x}$ and $\frac{2+2x}{2-6x}$ appear very analogous particular cases of $\frac{a+ax}{b-cx}$, but we shall see that, considered as functions of x , they are as strikingly different as x^a and a^x .

(28.) In all that has preceded, we have considered functions with reference only to one subject, or as functions of one magnitude. We shall denote a function in which two or more magnitudes are considered, in the usual way, by such symbols as

$$\phi(x, y) \quad \phi(x, y, z) \quad \phi(x, \psi x, \chi x.)$$

Thus $\psi x + x^2 \chi x$ is a case of $\phi(x, \psi x, \chi x.)$ and is a function of x only, but directly, as well as through ψx and χx . Similarly, $\psi(x, \chi(y+z))$ is a function of x, y , and z , but of the two latter through $y+z$; so that, if y and z vary, and $y+z$ remain constant, $\psi(x, \chi(y+z))$ does not vary. As we are principally concerned with functions of one subject, we shall defer further definition.

(29.) The direct question of the formation of a functional equation, which shall have for one solution $\phi x = ax$, may be answered in an infinite number of ways. Suppose we wish to have an equation which shall give $\phi x = x^2$. As all our operations are independent of the magnitude or form of the subjects, we have (a representing a known function) $\phi ax = (ax)^2$, between which and the former equation we may eliminate x wholly or partially: that is, if we call the first equation $U = 0$, and the second $V = 0$, and if βx be another known function of x , we have $V + \beta x U = 0$ when $\phi x = x^2$, or

$$\phi ax + \beta x \phi x - \{(ax)^2 + x^2 \beta x\} = 0,$$

of which, give a and β what form we may, $\phi x = x^2$ is one solution: and, as there are two arbitrary functions, we may determine them algebraically from any conditions. But we are not to assume that $\phi x = x^2$ is the only solution of the preceding. Suppose, for instance, $ax = ax$ and $\beta x = -a^2$, (or $-a^2 x^0$), we have

$$\phi(ax) = a^2 \phi x,$$

of which one solution is $\phi x = x^2$, but of which $x^2 \xi x$ is also a solution, if there can be a function ξ which shall not be altered by changing x into ax , or if a solution can be found to $\xi ax = \xi x$. For in that case

$$\phi(ax) = (ax)^2 \xi(ax) = a^2 x^2 \xi x = a^2 \phi x.$$

We have thus made an indefinite solution of $\phi(ax) = a^2 \phi x$ depend upon finding any number of functions of x which shall not be altered by changing x into ax . A general solution to which we shall afterwards come is,

$$\text{If } \phi(ax) = a^2 \phi x, \phi x = x^2 \times \text{any } f^0 \text{ of } \left(\cos 2\pi \frac{\lambda x}{\lambda a} \right)$$

with certain limitations on the word *any* derived from our future consideration of inverse functions.

(30.) To find a functional equation, admitting of two particular solutions, $\omega_1 x$ and $\omega_2 x$, we may evidently take $F\{\phi ax - \omega_1 ax, \phi \beta x - \omega_2 \beta x, \dots, \phi x - \omega_1 x, \phi x - \omega_2 x\} = 0$;

where a, β , &c. are known functions, and every term contains none but positive powers of $\phi ax - \omega_1 ax$, &c. But this case may be reduced to the last, if a function ξx can be found which will give the same results whether $\omega_1 x$, or $\omega_2 x$ be substituted for x ; or if a form of ξ can be found to $\xi \omega_1 x = \xi \omega_2 x$. For, if the value of the two last be called θx , and if an equation be formed from the last Article by means of $\xi \phi x - \theta x = 0$, $\xi \phi ax - \theta ax = 0$, &c., then that equation will be satisfied either by $\phi x = \omega_1 x$, or by $\phi x = \omega_2 x$.

(31.) Before proceeding further we must investigate the properties of several functional relations. And first, as to the algebraical inverse of ϕx . We have seen that ϕx may have more inverse functions than one; for example, the inverses of x^2 are the two values of $x^{\frac{1}{2}}$; those of $ax^2 + bx$ are

$$\frac{-b + \sqrt{b^2 + 4ax}}{2a} \text{ and } \frac{-b - \sqrt{b^2 + 4ax}}{2a}.$$

Again, $\cos 2\pi x$ has an infinite number of inverses, all contained in the formula

$$\frac{1}{2\pi} (\cos^{-1} x) \pm m,$$

where m is any whole number. Here $\cos^{-1} x$ placed in brackets signifies an angle less than π , and $\cos^{-1} x$ is the inverse of $\cos x$, or the angle whose cosine is x .

The inverses of e^x are infinite in number; for since e^x in its most general form (m being a whole number) is $e^{x \pm 2m\pi \sqrt{-1}}$, if we put $\psi x = e^{x \pm 2m\pi \sqrt{-1}}$, and λx for the numerical logarithm of x , we find $x \pm 2m\pi \sqrt{-1} = \lambda \psi x$, in which, if the inverse $\psi^{-1} x$ be substituted for x , which, by definition, gives $\psi \psi^{-1} x = x$, we have $\psi^{-1} x = \lambda x \pm 2m\pi \sqrt{-1}$.

The following examples of direct and inverse functions may be verified by the student.

1. Examples of direct functions which are their own inverses:

$$x, \frac{1}{x}, a - x, \frac{x-2}{x-1} (a^n - x^n)^{\frac{1}{n}}, \log(a - e^x)$$

$$\log\left(\frac{e^x - 2}{e^x - 1}\right), \log \log \frac{e^x + 1}{e^x - 1}.$$

Calculus of
Functions.

Calculus of Functions. The method by which these may be derived will presently be explained. They are here given to be verified.

2. The functions, in the second of the following columns are severally inverse to the opposite functions in the first.

$x + a$	$x - a$
bx	$\frac{x}{b}$
$a + bx$	$\frac{x - a}{b}$
$\frac{a + bx}{a' + b'x}$	$-\frac{a - a'x}{b - b'x}$
$\log x$	e^x , or $\log^{-1} x$
$\sin x$	$\sin^{-1} x$, angle whose sine is x .
$\cos x$	$\cos^{-1} x$, angle whose cosine is x .
x^n	$\frac{1}{x^n}$
ax^b	$\left(\frac{x}{a}\right)^{\frac{1}{b}}$
$ax^2 + bx + c$	$\frac{-b \pm \sqrt{b^2 - 4a(c-x)}}{2a}$
a^{e^x}	$\frac{\lambda^2 x - \lambda^2 a}{\lambda b}$ (λ^2 is log of log)
$\log(a + b e^x)$	$\log\left(\frac{e^x - a}{b}\right)$.

(32.) From comparison of various algebraical cases it will appear that the inverses of the equation $y = \psi x$ may be all reduced to any one inverse of the equation $y e^{2\pi m \sqrt{-1}} = \psi x$, the different forms of which, arising from different whole values given to m , will present the various inverses of $y = \psi x$. This is the case whenever the operation of inversion is direct, not depending upon any subsidiary inverses.* But, when subsidiary inversions take place, then each quantity inverted should be previously multiplied by the form $e^{2\pi n \sqrt{-1}}$, where n is a whole number. And for the multiplier we may

write $(1)^m$, if we recollect that $(1)^{\frac{m}{n}}$ has n different values. For instance, we shall invert

$$(x^2 - 1)^3 = y, \text{ or } (x^2 - 1)^3 = y(1)^m.$$

Let us choose† the direct arithmetical form of inversion:

$$x^2 - 1 = \sqrt[3]{y(1)^{\frac{m}{3}}} \quad x^2 = \{1 + \sqrt[3]{y(1)^{\frac{m}{3}}}\} (1)^n$$

$$x = \sqrt{1 + \sqrt[3]{y(1)^{\frac{m}{3}}}} (1)^{\frac{n}{2}}$$

or if $\psi x = (x^2 - 1)^3$ $\psi^{-1} x = \sqrt{1 + \sqrt[3]{x(1)^{\frac{m}{3}}}} (1)^{\frac{n}{2}}$ where m and n are any whole numbers. The cases contained reduce themselves to six, as follows, (p and q being whole numbers, and $1, r, r^2$ being the cube roots of unity.)

* For example, the usual inversion of $x^3 + ax$ by Cardan's formula requires the inversion of $z^6 + bz^3$, and all that can be said is that the method fails to present one form which contains inverses required, and inverses required only. But another form is frequently given, in which this is not the case.

† Let $\sqrt[3]{y}$ signify the arithmetical cube root of y , in opposition to $(y)^{\frac{1}{3}}$ of which $\sqrt[3]{y}$ is one particular case.

	Form of m .	Form of n .	Corresponding Inverse.
1.	$3p$	$2q$	$\sqrt{1 + \sqrt[3]{x}}$
2.	$3p$	$2q + 1$	$-\sqrt{1 + \sqrt[3]{x}}$
3.	$3p + 1$	$2q$	$\sqrt{1 + r\sqrt[3]{x}}$
4.	$3p + 1$	$2q + 1$	$-\sqrt{1 + r\sqrt[3]{x}}$
5.	$3p + 2$	$2q$	$\sqrt{1 + r^2\sqrt[3]{x}}$
6.	$3p + 2$	$2q + 1$	$-\sqrt{1 + r^2\sqrt[3]{x}}$.

Calculus of Functions.

The first of these inverses we shall call the arithmetical inverse, or, where distinction between it and the functional inverses is necessary, the arithmetico-algebraical inverse, being that algebraical inverse in which the processes of Algebra are supposed to take no wider form than those of Arithmetic. All the six satisfy the equation of definition $\psi \psi^{-1} x = x$, from which it would seem that we might argue as follows. In the preceding equation write ψx instead of x , which gives $\psi(\psi^{-1} \psi x) = \psi x$; but when $\psi v = \psi x$, $v = x$, therefore $\psi^{-1} \psi x = x$, or if ψ^{-1} be inverse to ψ , ψ is also inverse to ψ^{-1} . But the clause in Italics contains a *petitio consequentiæ*, as the algebraist will readily perceive; for from $\psi v = \psi x$, can only be inferred that one or more values of v are severally $= x$. And it will be found, upon trial, that while the arithmetical inverse does satisfy $\psi^{-1} \psi x = x$, the others do not. For instance, putting ψx instead of x , in all the six inverses already found, we shall have the following results for $\psi^{-1} \psi x$.

1. $\psi^{-1} \psi x = x$
2. $\psi^{-1} \psi x = -x$
3. $\psi^{-1} \psi x = \sqrt{1 - r + rx^2}$
4. $\psi^{-1} \psi x = -\sqrt{1 - r + rx^2}$
5. $\psi^{-1} \psi x = \sqrt{1 - r^2 + r^2 x^2}$
6. $\psi^{-1} \psi x = -\sqrt{1 - r^2 + r^2 x^2}$.

(33.) Even in the results of $\psi \psi^{-1} x$, we shall find a difference of form, if we agree not to suppress r^2, r^6 , &c. because they are severally equal to 1, &c. Thus the six forms (they are identical in value) are

1. x
2. $\{(-1)^2 - 1 + (-1)^2 \sqrt[3]{x}\}^3$
3. $r^3 x$
4. $\{(-1)^2 - 1 + (-1)^2 r \sqrt[3]{x}\}^3$
5. $r^6 x$
6. $\{(-1)^2 - 1 + (-1)^2 r^2 \sqrt[3]{x}\}^3$;

and these, writing ψx instead of x , give the six forms of ψx , from which the six inverses follow arithmetically; thus, from

$$(x^2 - 1)^3 = r^3 \psi x, \text{ or } r^3 y,$$

we find arithmetically

$$x = \sqrt{1 + r \sqrt[3]{y}};$$

whence value (3.) of $\psi^{-1} x$. From

$$(x^2 - 1)^3 = \{(-1)^2 - 1 + (-1)^2 r \sqrt[3]{y}\}^3,$$

we find

$$x = (-1) \sqrt{1 + r \sqrt[3]{y}};$$

whence value (4.) of $\psi^{-1} x$, and so on. Whence, and from similar processes in the case of other functions, we lay down the following definition, and deduce the following theorem.

Definition.—Two operations are said to be convertible when the value of the result is independent of the order in which they are performed. Thus ϕ and ψ are convertible when $\phi \psi x = \psi \phi x$.

Theorem.—Every inverse is convertible with one or other of the forms of the direct function. This theorem assumes the convertibility of the direct function with the arithmetical inverse which we have seen; and we

Calculus of Functions. have shown how to give the direct function the form by &c., so that the recurrence has already begun with Calculus of Functions. which any inverse may be arithmetically derived from it. $\phi^m x = x$.

Thus $(x^2 - 1)^3 = r^3 \psi x$, giving ψx the form $\frac{(x^2 - 1)^3}{r^3}$;

this form is convertible with the corresponding inverse form $\sqrt{1 + r\sqrt[3]{x}}$.

For example, the inverses $1 + \sqrt{x}$ and $1 - \sqrt{x}$ are not both convertible with $(x - 1)^{\frac{1}{2}}$; but the first is convertible with $(x - 1)^{\frac{1}{2}}$, and the second with the equivalent form $(1 - x)^{\frac{1}{2}}$. Again, $\sin x$ is convertible with $\sin^{-1} x$, but not with $\sin^{-1} x - 2\pi$; the latter being convertible with $\sin(x + 2\pi)$, another form of $\sin x$.

(34.) When we drop the supposition that ψx represents any form of a function, and confine it to one form, we shall let $\psi^{-1}x$ stand for its arithmetical or *convertible* inverse, and (in order to remove the notation of exponents where the analogy does not exist) we shall signify any *inconvertible* inverse by $\psi_{-1}x$. Then, from definition, $\psi^{-1}\psi x = x$, but $\psi_{-1}\psi x$ is not always $= x$.

Those factors, or functional symbols, which are introduced to change the form of a function, and which are symbolical representations of changes of form only, we call *formal* factors or functions, in opposition to *real* factors or functions, which produce a change of value.

*Theorem.** If ψ_{-1} be any invertible inverse of the form ψ , and if $\psi_{-1} \psi x = \phi x$, and if the successive functions of ϕx be taken, namely $\phi^2 x$, $\phi^3 x$, &c., then shall $\psi \phi^n x$ always be a form of ψx : and all the forms of ψx shall be contained among them.

Let us first consider $\psi \phi x$, or $\psi (\psi_{-1} \psi x)$. Let ρ be the formal symbol, which makes $\psi_{-1} x$ the arithmetical inverse to $\rho \psi x =$ the given form. Then, as we have seen, $\psi \psi_{-1} x$ gives x in the form ρx , and $\psi \psi_{-1} (\psi x) = \rho \psi x$ another form of ψx . Again, in $\psi \psi_{-1} x = \rho x$ repeat the operations, which gives $\psi \psi_{-1} \psi \psi_{-1} x = \rho^2 x$, the same or another form of x ; for if $\rho x = x$ in value, $\rho^2 x = \rho x = x$ in value. Write ψx instead of x in the last equation, then $\psi \psi_{-1} \psi \psi_{-1} \psi x = \rho^2 \psi x$, the same or another form of ψx : or $\psi (\psi_{-1} \psi \psi_{-1} \psi x) = \rho^2 \psi x$, that is, $\psi \phi^2 x = \rho^2 \psi x$, and so on.

That all the forms of ψx may be thus found, follows from all the inverses having forms of the function from which they are arithmetically deducible.

Hence, if we represent the various inconvertible inverses of ψ by ψ_{-1} , ψ_{n-1} , &c., and if $\psi_{-1} \psi x = \phi x$, $\psi_{n-1} \psi x = \phi_n x$, &c., the several results

$\psi x, \psi \phi, x, \psi \phi^2 x, \psi \phi^3 x, \&c.$
 $\psi x, \psi \phi, x, \psi \phi' x, \psi \phi'' x, \&c.$
 $\&c. \quad \&c. \quad \&c. \quad \&c.$

are all forms of ψx . If we consider one horizontal series (the first) we see that, if ψx have only a finite number of inverses, there can only be a finite number of corresponding forms, answering to a finite number of values of the succession

$$x, \phi, x, \phi^2 x, \phi^3 x, \&c.;$$

after the first value of these, which is equal to a preceding value, the series recommences, and x will be the first which reappears. For (we are now speaking of values only) let $\phi^{n+m}x = \phi^n x$, or $\phi^m(\phi^n x) = \phi^n x$. Let $\phi^n x = z$; then $\phi^m z = z$, or† $\phi^m(x) = x$, $\phi^{m+1}x = \phi x$,

* We consider the demonstration of this theorem incomplete in several points: it is worth further consideration.

Remember, that we only employ general functional equations,

&c., so that the recurrence has already begun with Calculus of
 $\phi^m x = x$. Functions.

(35.) When $\phi^m x = x$, ϕx is called a *periodic function* of the m th order. The above is an *a priori* proof of the possibility of such functions.

(36.) To show a case of the preceding theorem, let $\psi x = (x^2 - 1)^3$, $\psi_{-1} x = \sqrt{1 + r\sqrt[3]{x}}$, whence

$$\begin{aligned}\psi_{-1}\psi x &= \phi x = \sqrt{1-r+rx^2} \\ \phi^2 x &= \sqrt{1-r+r\{\sqrt{1-r+rx^2}\}^2} \\ &= \sqrt{1-r^2+r^2x^2} \\ \phi^3 x &= \sqrt{1-r^3+r^3x^2} = x, \text{ since } r^3 = 1.\end{aligned}$$

$$\left. \begin{aligned} \psi \phi x &= (-r + r x^2)^3 = r^3 (x^2 - 1)^3 \\ \psi \phi^2 x &= (-r^2 + r^2 x^2)^3 = r^6 (x^2 - 1)^3 \end{aligned} \right\} \begin{array}{l} \text{forms of} \\ (x^2 - 1)^3. \end{array}$$

Again, let $\psi x = \sin x$, $\psi_{-1} x = \sin^{-1} x + 2\pi$

$$\psi_{-1} \psi x = \phi x = x + 2\pi, \quad \phi^n x = x + 2n\pi$$

this function is *not* periodic; but $\sin x$ has an infinite number of inverses; and $\psi \phi^n x = \sin(x + 2n\pi)$, which includes all one set of forms of ψx . Similarly, $\psi_{-1} x = \sin^{-1} x - 2\pi$ gives all the forms included in $\sin(x - 2n\pi)$. But $\psi_{-1} x = \pi - \sin^{-1} x$ gives $\phi x = \pi - x$ a periodic function; $\psi_{-1} x = 3\pi - \sin^{-1} x$ gives $\phi x = 3\pi - x$ another periodic function, &c.

(37.) We shall now proceed to the consideration of the successive functions ϕx , $\phi^2 x$, $\phi^3 x$, &c. ; and, firstly, as to their values or the limit of their values, for a particular value of x .

Theorem. The limit (if there be one) of $\phi^n x$, made by increasing n without limit, is a solution of the equation $\phi x \equiv x$.

For let us suppose that n can be made so great that $\phi^n x$ and $\phi^{n+1} x$ shall not differ from a limit L by so much as l and l_1 , which two latter may be made as small as we please. That is, let

$$\begin{aligned}\phi^n x &= L + \text{less than } l, \\ \phi^{n+1} x &= L + \text{less than } l_1.\end{aligned}$$

But $\phi^{n+1}x = \phi(\phi^n x)$, that is, $L +$ less than $l_1 = \phi(L + \text{less than } l)$; or, since l and l_1 may be made as small as we please, $L = \phi(L)$. If this equation have only one possible root, then the limit is independent of the value of x first chosen; if it have more than one possible root, some values of x may cause $\phi x, \phi^2 x, \&c.$ to approach one limit, and some another.

(38.) It may happen, that the values of $\phi^n x$ may approach in a regulated succession to different limits. Suppose three limits, L , L' , and L'' , to which $\phi^n x$, $\phi^{n+1} x$, and $\phi^{n+2} x$ approach in succession; then, by preceding reasoning, $\phi^{n+3} x = \phi^n x$, or $\phi^3 x = x$ is the equation of which L , L' , and L'' are different roots.

(39.) The preceding theorem is sometimes used explicitly in different parts of Mathematics. As when it is inferred that the value of

$\frac{1}{2 + \frac{1}{2} + \text{&c. ad. inf.}}$ is x where $x = \frac{1}{2 + x}$;

let $\phi x = \frac{1}{2+x}$ then $\phi^2 x = \frac{1}{2+\frac{1}{2+x}}$, &c., the limit of

which is the solution of $\phi x = x$.

independent of the actual values of the subject of the symbols. Thus $\phi z = z$ is the same as $\phi x = x$.

Calculus of Functions.

(40.) But this theorem is used in a less defined form throughout every part of the practice of Algebra, from Division and Involution to Newton's rule for approximating to the roots of equations, and the similar processes of the Differential Calculus; all of which depend upon the following: that if a be an assumed value for x (practically, it must be rather near) in the equation

$$\phi x = 0; \text{ and if } \psi a = a - \frac{\phi a}{\phi' a}, \text{ where } \phi' a \text{ is the value}$$

of the differential coefficient of ϕx for $x = a$, the results of the succession $\psi a, \psi^2 a, \&c.$, will approach a limit* which is a solution of $\phi x = 0$; or, as we should now

say, of $x - \frac{\phi x}{\phi' x} = x$, that is, either of $\phi x = 0$, or of

$\frac{1}{\phi' x} = 0$. The first is the practical theorem, the second illustrates the difficulty sometimes found in applying it.

(41.) Thus, in any commercial transaction, if its funds be acted upon nearly according to the same law every year, and in such a manner that they do not tend to diminish or accumulate without limit, the effect of successive years will render it comparatively immaterial how the funds stood at the commencement, and will tend to reduce the business to a state of permanency, in which the receipts and expenditure are equal.† And various mechanical problems, in which the disappearance of the effects of the primitive state of the system is owing to a succession of resistances, partake of the same analogy.

(42.) We may illustrate the value of $\phi^n x$ geometrically as follows. Take two rectangular axes $O X, O Y$, (fig. 1,) cut by a line $O A$, equally inclined to both. Let $O 12, \&c.$ be the curve whose equation is $y = \phi x$, and take $O M$ any value of x , the ordinate of which is $M 1$, then $M 1 = \phi(O M)$. Take $O N = M 1$, the ordinate of which is $N 2$, whence $N 2 = \phi(M 1) = \phi^2(O M)$, and so on. By constructing different curves, the reader will see that the finite limit (if there be one) of $\phi^n(O M)$ must be that position of the ordinate at which $O A$ cuts the curve, or at which $\phi x = x$.

(43.) Or take any table in which the tabulated quantity is at some part or other equal to its argument; a table of the *mean duration* (commonly called the *expectation*) of human life is convenient for the purpose. For example, in the Northampton Table,‡ opposite to 28 we find 29.30, and opposite to 29 we find 28.79, so that, if ϕx represent the mean duration of a life aged x , the root of $\phi x = x$ lies between 28 and 29. If, going into this Table with any age, we take the nearest whole year of mean duration, and repeat the process, the result will finally be a repetition of 29, in whatever part of the Table we commence. For instance,

* In the Appendix to the second edition of Legendre's *Théorie des Nombres*, the principle is applied to the solution of all classes of algebraical equations.

† Mutual insurance offices would be such when they reached their stationary points, if they did not guarantee a fixed sum at least to their insurers. And if Dr. Price had well considered that the rate of interest depends on the quantity of money, he might have seen reason to suppose that his farthing put out to compound interest at the beginning of the world would never have exceeded a fixed sum. The theory of the unlimited tendency of population to increase might, for any thing its advocate could know to the contrary, have required a similar modification independent of the price of provisions.

Calculus of Functions.

(44.) It is evident that $\phi^n x$ may be considered as a function of n , and its second function might be taken

with respect to n , which would be denoted by $\phi^{\phi^n x}$, &c. But, to avoid this complication of notation, let us signify $\phi^n x$, treated as a function of n and x , by the capital letter Φ , so that $\phi^n x = \Phi(n, x)$. That this will also be true in the case of fractions, is evident from the following reasoning. Since $(\phi^m)^n x$ will become $\Phi(m n, x)$ generally, if the operations be those of ordinary Algebra, (in which there is no distinction between the results of whole numbers, *generally expressed*, and fractions) it

follows that if $m = \frac{p}{n}$, and if $\phi^{\frac{p}{n}}$, (meaning as yet un-

known, $\phi^{\frac{p}{n}} x$ being merely considered as a representation

of $\Phi\left(\frac{p}{n}, x\right)$) be called ψ , then $\psi^n x$ will be $\Phi(p, x)$, or

$(\phi^{\frac{p}{n}})^n x = \Phi(p, x) = \phi^p x$; so that $\Phi\left(\frac{p}{n}, x\right)$ is one of

the n th functional inverses of ϕx , or may be called $\phi^{\frac{p}{n}} x$ in the sense explained in (16). We shall proceed to find some general forms of $\phi^n x$.

(45.) Since we shall afterwards see that expressions of the same form, algebraically speaking, (such as $a + b x$ and $c + e x$), may present important functional differences, we shall not call $a + b x$ and $c + e x$ particular cases of the same general form, but *cognate* forms. And all the functions hitherto imagined or treated of will fall under one or other of the following cases, when considered with respect to the properties of their successive functions.

1. Cases in which the successive functions all assume *different* forms, algebraically speaking, *ad infinitum*. Such is $1 + x^2$, the second function of which is $2 + 2x^2 + x^4$, and so on. Such also is $\log x$, the second function of which is $\log \log x$, &c.

2. Cases in which the successive functions of x assume only a finite number of recurring *different* forms. In this case we have seen that $\phi^n x$ will for some particular value of n become equal to x , $\phi^{n+1} x$ to ϕx , &c. See (7.) and (36.)

3. Cases in which all the successive functions are cognate forms, either with or without recurrence. The only cases of this kind known in common Algebra are

$$a + b x, \frac{a + b x}{a' + b' x}, \text{ and } a x^b.$$

(46.) A general method has been given by Laplace,* which reduces the determination of successive functions, and indeed the solution of functional equations of all kinds, to the solution of equations of differences.

* *Mém. des Savans Etrangers*, 1773.

Calculus of Applied to the determination of successive functions, it Functions. is as follows:

Let $x, \phi x, \phi^2 x, \&c.$, be considered as the successive terms of $u_n = \Phi(n, x) = \phi^n x$. Then, $u_{n+1} = \phi^{n+1} x = \phi \phi^n x = \phi u_n$, or u_{n+1} is a given function of u_n . But, unfortunately, we know so little of general methods for integrating $u_{n+1} = \phi u_n$, that this is of little use in finding general solutions.*

But this method has the following use. It points out that we are not to consider the successive functions of ϕx as absolutely irreducible to the same form, because they present differences which are in common Algebra considered as essential. For instance,† let

$$\phi x = \frac{2x}{1-x^2},$$

whence

$$u_{n+1} = \frac{2u_n}{1-u_n^2},$$

which equation can be integrated as follows: assume $u_n = \tan v_n$, then $u_{n+1} = \tan v_{n+1} = \tan 2v_n$, from the equation; consequently, $v_{n+1} = 2v_n$, or $v_n = c \cdot 2^n$, and $u_n = \tan(c \cdot 2^n)$, which may, by the exponential formula, be reduced to the following, as to form:

$$u_n = \phi^n x = \sqrt{-1} \frac{1-c^2}{1+c^{2^n}},$$

where c must be determined from the condition that $u_0 = x$, which gives

$$x = \sqrt{-1} \frac{1-c}{1+c}, \text{ or } c = \frac{\sqrt{-1}-x}{\sqrt{-1}+x};$$

so that, if $\phi x = \frac{2x}{1-x^2}$,

$$\phi^n x = \sqrt{-1} \frac{(\sqrt{-1}+x)^{2^n} - (\sqrt{-1}-x)^{2^n}}{(\sqrt{-1}+x)^{2^n} + (\sqrt{-1}-x)^{2^n}};$$

in the reduction of which for any particular value of n , all impossibility will vanish, as is sufficiently obvious to the practised algebraist.

Another example given in the same Memoir is the following: If $\phi x = 2x^2 - 1$, or $u_{n+1} = 2u_n^2 - 1$, the integral of which is (assuming $u_n = \cos v_n$, and proceeding as before)

$$u_n = \frac{1}{2} \{c^{2^n} + c^{-2^n}\}$$

and

$$\phi^n x = \frac{1}{2} \left\{ (x + \sqrt{x^2-1})^{2^n} + (x - \sqrt{x^2-1})^{2^n} \right\}$$

(47.) The above will be found to succeed when the values of n are fractional or negative. If, for instance, we make $n = -1$, we find in the second case

$$\phi^{-1} x = \frac{1}{2} \left\{ (x + \sqrt{x^2-1})^{\frac{1}{2}} + (x - \sqrt{x^2-1})^{\frac{1}{2}} \right\}$$

which is an equivalent form to $\left(\frac{1+x}{2}\right)^{\frac{1}{2}}$, the real inverse of $2x^2 - 1$. But it may be suspected that this is

* Whether indeed this method is to be called reduction of functional to differential, or of differential to functional, equations, must depend upon which class has had most substantial progress made in its solution.

† *Memoirs of the Analytical Society*, p. 50. The Paper in which this is found is attributed, we believe correctly, to Sir John Herschel, whose treatise on the Calculus of Differences is one of the richest analytical Works of its size extant.

not the most general form of $\phi^n x$, when n is fractional, for the following reasons.

(48.) The arbitrary constant introduced in the integration of an equation need not be considered as never changing; it is sufficient that it does not change under any changes which the verification of the equation may render necessary. In the Differential Calculus, in which every possible change of value of the independent variable is contemplated, the constant must under no circumstances change with a change in the variable, and therefore cannot be a function of it. But in the Calculus of Differences, in which, generally speaking, the variable is considered as changing only from one whole number to another, the arbitrary constant is any function of the variable which is the same for all whole numbers, the most general form of which is $\psi(\cos 2n\pi)$. Thus the solution of $u_{n+1} = u_n + 1$ is not $u_n = n + C$, but $u_n = n + \psi(\cos 2n\pi)$; where, however, ψ must not contain the inversion of the cosine. Again, in a functional equation, the arbitrary constant may be any function of x , which does not change upon substituting for x all the known operations which are performed upon it in the equation. Thus, one solution of $\phi(x^2) = x\phi x$ is $\phi x = x$; but if a function ξx can be found which shall not change when x^2 is substituted for x , that is, if the equation $\xi x^2 = \xi x$ admit of solution, then $x\theta\xi x$ is a solution of $\phi(x^2) = x\phi x$, where θ is any function we please, which does not invert ξ ; for

$$\xi x^2 = \xi x, \theta\xi x^2 = \theta\xi x, \text{ and } x^2\theta\xi x^2 = x \times x\theta\xi x.$$

Taking the second instance in (47.), in which $\phi x = 2x^2 - 1$ and $u_{n+1} = 2u_n^2 - 1$, it appears, then, that if we can so find ξx as that $\xi(2x^2 - 1) = \xi x$, the arbitrary function $\theta\xi x$ may be substituted for the constant c ; for the change of n into $n+1$ changes x into ϕx , or $2x^2 - 1$, and ξx remains unaltered. Hence the integral is (see Remark at the end of this Treatise)

$$u_n = \frac{1}{2} \{(\theta\xi x)^{2^n} + (\theta\xi x)^{-2^n}\}$$

Now there is no objection, consistently with the conditions, to supposing $\theta\xi x$ to contain n among the constants which are introduced, provided the functions of n thus considered do not change in changing n from one whole number to another. For instance, $\theta\xi x$ might be $\xi x \cdot \cos 2\pi n$. And though, in this case, all the whole values of n would not give $\phi^n x$ different in form from the value in (47.), the fractional values of n would.

When we talk of the most general form of a function, we must be considered as speaking conjecturally, for we have no test by which to try the generality of any solution whatsoever. Though n is not an assignable function of x , yet there does exist between them a species of functional relation; namely, that a change of n into $n+1$ is equivalent to a change of x into $2x^2 - 1$. Either, therefore, more general forms of the functional inverses may be given than are explicitly contained in the expression for $\phi^n x$, or there is some connection between ξx and $\cos 2\pi n$, which must oblige us to consider one as a function of the other, or at least as having this sort of relation, that $\phi(\xi x, \cos 2\pi n)$ is not more general than $\phi(\xi x)$.

(49.) Much of what has been done in the Calculus of Functions depends upon a class* of forms to which we

* Mr. Babbage was the first who made this form known; but he requests us to state that the method of expression, $\phi \alpha \phi^{-1} x$, was suggested to him by W. H. Maule, Esq., of Trinity College, Cambridge, and of Lincolns Inn.

Calculus of now proceed. By observing a few processes of Algebra Functions. functionally, we shall see that we are continually using such forms; though, where value or developement is the prominent idea, we lose sight of mere form.

In the formula $\sqrt{x^2 + c}$, we see the direct and inverse operations $\sqrt{\quad}$ and $(\quad)^2$; but the inverse not performed upon the direct function, but upon a function of it.

The steps are $x, x^2, x^2 + c, \sqrt{x^2 + c}$. Similarly, in expanding $\sin mx$ in terms of $\sin x$, we are seeking for $\sin m \sin^{-1} p$ in terms of p ; and the steps are $p, \sin^{-1} p, m \sin^{-1} p, \sin m \sin^{-1} p$. Again, x^n , when represented by $e^{n \log x}$, is another instance.

And the algebraist cannot but have remarked, that triple operations of this sort give expressions of more utility as well as simplicity of relations than any others in which the first and third are not inverse. Thus $\sqrt{x^2 + c}$ is of a much higher degree of importance than $\sqrt{x^2 + c}$ in all the practice of Algebra.

The general form of such functions is either $\phi \alpha \phi^{-1} x$, $\phi \alpha \phi^{-1} x$, $\phi^{-1} \alpha \phi x$, or $\phi^{-1} \alpha \phi x$; of which we shall reject the second and fourth, and not consider them at present. Let us call $\phi \alpha \phi^{-1} x$ a derivative* of αx , (a derivative of αx by ϕ , if it be necessary to distinguish ϕ .) We shall then have the following theorems.

(A.) Derivatives of derivatives of αx are derivatives of αx .

Let $\phi \alpha \phi^{-1} x$ be a derivative of αx ; and $\psi (\phi \alpha \phi^{-1} x)$ $\psi^{-1} x$, or $\psi \phi \alpha \phi^{-1} \psi^{-1} x$ a derivative of $\phi \alpha \phi^{-1} x$. Then, if $\psi \phi x = \chi x$, we have $\psi x = \chi \phi^{-1} x$, $x = \chi \phi^{-1} \psi^{-1} x$, or $\chi^{-1} x = \phi^{-1} \psi^{-1} x$, whence $\psi \phi \alpha \phi^{-1} \psi^{-1} x$ is $\chi \alpha \chi^{-1} x$,

another derivative of αx . Thus $\log (e^x)$, or $n x$, is one derivative of x^n , therefore $\sin (n \sin^{-1} x)$ is another.

(B.) If μ and ν be corresponding derivative forms of α and β , then $\mu \nu$ is a derivative of $\alpha \beta$. For let $\mu x = \phi \alpha \phi^{-1} x$, $\nu x = \phi \beta \phi^{-1} x$. Then $\mu \nu x = \phi \alpha \phi^{-1} \phi \beta \phi^{-1} x$. But $\phi^{-1} \phi x = x$; therefore, $\phi^{-1} \phi \beta \phi^{-1} x = \beta \phi^{-1} x$, or $\mu \nu x = \phi \alpha \beta \phi^{-1} x$, whence $\mu \nu$ is a derivative of $\alpha \beta$.

(C.) If two functions α and β be inverse to one another, or convertible each with the other, then their corresponding derivatives are inverse or convertible. Thus, if $\alpha \beta x = x$, $\phi \alpha \phi^{-1} \phi \beta \phi^{-1} x = \phi \alpha \beta \phi^{-1} x = \phi \phi^{-1} x = x$. Or, if $\alpha \beta x = \beta \alpha x$, $\phi \alpha \phi^{-1} \phi \beta \phi^{-1} x = \phi \alpha \beta \phi^{-1} x = \phi \beta \alpha \phi^{-1} x = \phi \beta \phi^{-1} \phi \alpha \phi^{-1} x$.

(D.)† The successive functions of the derivatives of αx are the corresponding derivatives of the successive functions of αx . Thus $(\phi \alpha \phi^{-1})^2 x = \phi \alpha \phi^{-1} \phi \alpha \phi^{-1} x = \phi \alpha^2 \phi^{-1} x$. Again, if $(\phi \alpha \phi^{-1})^n x = \phi \alpha^n \phi^{-1} x$, then $(\phi \alpha \phi^{-1})^{n+1} x = \phi \alpha \phi^{-1} (\phi \alpha \phi^{-1})^n x = \phi \alpha \phi^{-1} \phi \alpha^n \phi^{-1} x = \phi \alpha^{n+1} \phi^{-1} x$; so that this theorem, being true for the second function, is true for all which succeed.

(E.) The derivatives of a periodic function are periodic functions of the same order. Thus, if $\alpha^n x = x$, $(\phi \alpha \phi^{-1})^n x = \phi \alpha^n \phi^{-1} x = \phi \phi^{-1} x = x$.

(F.) If two functions be algebraically cognate in form, so will be all their corresponding derivatives. For if we take $2 + 3x$ and $3 + 4x$, their derivatives $\phi (2 + 3 \phi^{-1} x)$ and $\phi (3 + 4 \phi^{-1} x)$ will be particular cases of $\phi (m + n \phi^{-1} x)$.

* We do not like to suggest any other than a generic name. Any person may specify to himself what derivative he will call it.

† This and the next theorem are due to Mr. Babbage. See *Philosophical Transactions*, 1815.

(50.)* If functions αx and βx be given, neither of which are periodic, required to find whether β be a derivative of α , and, if so, what derivative. Let $\beta x = \phi \alpha \phi^{-1} x$: for x write ϕx , and the preceding becomes $\beta \phi x = \phi \alpha x$, which equation is to be solved. Assume

$$\alpha^n x = A(n, x) \quad \beta^n y = B(n, y),$$

and from these two equations eliminate n ; giving

$$F(x, y, \alpha^n x, \beta^n y) = 0.$$

Between y and x suppose that relation to exist which would arise from putting arbitrary constants C and C' in place of $\alpha^n x$ and $\beta^n y$; that is, define $y = \phi x$ by the equation

$$F(x, y, C, C') = 0.$$

Then, since

$$\alpha^{n+1} x = A(n, \alpha x) \quad \beta^{n+1} y = B(n, \beta y),$$

elimination of n gives

$$F(\alpha x, \beta y, \alpha^{n+1} x, \beta^{n+1} y) = 0;$$

or $\beta y = \phi \alpha x$ satisfies the equation

$$F(\alpha x, \beta y, C, C') = 0;$$

consequently, the system of equations,

$$y = \phi x, \quad \beta y = \phi \alpha x,$$

are both true when $F(x, y, C, C') = 0$ is true: but these two, by elimination of y , give $\beta \phi x = \phi \alpha x$, or $\beta x = \phi \alpha \phi^{-1} x$. Therefore, ϕx must satisfy the condition $F(x, \phi x, C, C') = 0$.

(51.) As an example of the last theorem, let us ask what derivative is $a' + b'x$ of $a + bx$.

Here (22.) let us put $a + bx$ and $a' + b'x$ in the form $p(x + q) - q$, which gives

$$\beta y = b' \left(y + \frac{a'}{b' - 1} \right) - \frac{a'}{b' - 1}$$

$$\alpha x = b \left(x + \frac{a}{b - 1} \right) - \frac{a}{b - 1}$$

whence (22.)

$$\beta^n y = b'^n \left(y + \frac{a'}{b' - 1} \right) - \frac{a'}{b' - 1}, \text{ call this } C' - \frac{a'}{b' - 1}$$

$$\alpha^n x = b^n \left(x + \frac{a}{b - 1} \right) - \frac{a}{b - 1} \dots \dots \dots C - \frac{a}{b - 1}$$

eliminate n , which gives (writing C' and C for $\lambda C'$ and λC)

$$\lambda \cdot \left(y + \frac{a'}{b' - 1} \right)^{\lambda b'} - \lambda \cdot \left(x + \frac{a}{b - 1} \right)^{\lambda b} = C' \lambda b - C \lambda b';$$

or, writing C for $\log^{-1} (C' \lambda b - C \lambda b')$, which is merely an arbitrary constant, (we shall frequently make a similar change,)

$$\frac{\left(y + \frac{a'}{b' - 1} \right)^{\lambda b'}}{\left(x + \frac{a}{b - 1} \right)^{\lambda b}} = C$$

$$\phi x = C^{\frac{1}{\lambda b}} \left(x + \frac{a}{b - 1} \right)^{\frac{\lambda b'}{\lambda b}} - \frac{a'}{b' - 1}$$

$$\phi^{-1} x = C^{-\frac{1}{\lambda b'}} \left(x + \frac{a'}{b' - 1} \right)^{\frac{\lambda b}{\lambda b'}} - \frac{a}{b - 1}$$

* This theorem is due to M. Collins, who refers to it in the *Petersburg Transactions*, 6th series, vol. i. p. 350. We have not seen his demonstration.

Calculus of
Functions.

$$\begin{aligned}\alpha\phi^{-1}x &= bC^{-\frac{1}{\lambda b'}}\left(x + \frac{a'}{b'-1}\right)^{\frac{\lambda b'}{\lambda b}} - \frac{a}{b-1} \\ \phi\alpha\phi^{-1}x &= C^{\frac{1}{\lambda b}}\left(\alpha\phi^{-1}x + \frac{a}{b-1}\right)^{\frac{\lambda b'}{\lambda b}} - \frac{a'}{b'-1} \\ &= C^{\frac{1}{\lambda b}}b^{\frac{\lambda b'}{\lambda b}}C^{-\frac{1}{\lambda b}}\left(x + \frac{a'}{b'-1}\right)^{\frac{\lambda b'}{\lambda b}} - \frac{a'}{b'-1} \\ \left\{b^{\frac{\lambda b'}{\lambda b}} = b'\right\} &= b'\left(x + \frac{a'}{b'-1}\right) - \frac{a'}{b'-1} = \beta x.\end{aligned}$$

(52.) We can now illustrate what has been said in (27.) about functional distinctions. If, in the preceding case, $b' = 1$, then the form of ϕx , as derived from the preceding, is

$$C^{\frac{1}{\lambda b}}\left(x + \frac{a}{b-1}\right)^{-\frac{1}{\lambda b}} - \alpha,$$

which is useless. If a value could be derived, or a limit of ϕx , when $b' - 1$ diminishes without limit, the function $a' + x$ might be considered as a case of $a' + b'x$ upon principles adopted in Algebra.* But the pre-

ceding expression is simply $-C^{\frac{1}{\lambda b}} - \alpha$, which can in no sense be called a representation of the function to which we shall come, so long as C is a constant. But we have treated C as a constant of the Differential Calculus; whereas all that is necessary is, that it should be a function of x , which does not change when either αx , βx , ϕx , or $\phi^{-1}x$ is substituted for x . If we could give the general form, the preceding expression might become of the form $\alpha - \alpha$ when $b' = 1$; in which case its value might be determined by differentiation. For if P and Q be functions of b' , which become infinite when $b' - 1 = 0$, we have

$$P - Q = \lambda \frac{e^P}{e^Q} = \lambda \frac{e^P P'}{e^Q Q'},$$

where P' and Q' are the values $\frac{dP}{db'}$ and $\frac{dQ}{db'}$ when $b' = 1$; and the value of $P - Q$ may be finite if $P' = Q'$. But we proceed to find how $a' + x$ may be derived from $a + bx$.

(53.) Let

$$\beta y = a' + y \quad \alpha x = b\left(x + \frac{a}{b-1}\right) - \frac{a}{b-1}$$

$$\beta^n y = na' + y \quad \alpha^n x = b^n\left(x + \frac{a}{b-1}\right) - \frac{a}{b-1}$$

Let

$$\begin{aligned}na' + y &= C \\ b^n\left(x + \frac{a}{b-1}\right) - \frac{a}{b-1} &= C' - \frac{a}{b-1}\end{aligned}$$

from the last

$$n = \frac{\lambda C' - \lambda\left(x + \frac{a}{b-1}\right)}{\lambda b}$$

* By Algebra, we mean also the theory of limits: we consider that common Arithmetic introduces the theory of limits in such expressions as $\sqrt{2}$; nor can we find a meaning for the equation $\sqrt{8} = 2\sqrt{2}$, without either the theory of limits or Geometry. We assume, therefore, the former as a part of Algebra.

or

$$\phi x \text{ or } y = C - a' \frac{\lambda C' - \lambda\left(x + \frac{a}{b-1}\right)}{\lambda b}$$

and has the form

$$\begin{aligned}C + \frac{a}{\lambda b} \cdot \lambda\left(x + \frac{a}{b-1}\right) \\ \phi^{-1}x &= \varepsilon^{\frac{(x-C)\lambda b}{a}} - \frac{a}{b-1} \\ \alpha\phi^{-1}x &= b \cdot \varepsilon^{\frac{(x-C)\lambda b}{a}} - \frac{a}{b-1} \\ \phi\alpha\phi^{-1}x &= C + \frac{a'}{\lambda b}\left(\lambda b + (x - C)\frac{\lambda b}{a'}\right) \\ &= a' + x = \beta x.\end{aligned}$$

Calculus of
Functions.

(54.) We return to the subject of periodic functions. By (49.) it appears, that if αx be a periodic function of the n th order, then so is $\phi\alpha\phi^{-1}x$. So many different periodic functions, therefore, as we are able to find, *apparently*, so many different classes of periodic functions can we ascertain, each class being infinite in the number of its individual cases. For instance, $(1)^{\frac{1}{n}}x$ is a periodic

function of the n th order; so therefore is $\phi(1)^{\frac{1}{n}}\phi^{-1}x$, giving the following theorem, a particular case of which we have already arrived at in a different manner.

If y be any non-arithmetical root of $y^n - \phi^{-1}x = 0$, ϕy is a periodic function of x . Thus $\phi(-\phi^{-1}x)$

is a periodic function of the second order. Again, $\frac{1}{x}$ and

$1 - x$ are periodic functions of the second order; so also must be $\phi\left(\frac{1}{\phi^{-1}x}\right)$ and $\phi(1 - \phi^{-1}x)$; for instance,

$$\begin{aligned}\phi x = 2 + 3x \quad \phi\left(\frac{1}{\phi^{-1}x}\right) &= 2 + \frac{9}{x-2} = \frac{2x+5}{x-2} \\ \phi x = x^3 \quad \phi(1 - \phi^{-1}x) &= (1 - \sqrt[3]{x})^3\end{aligned}$$

We have seen (36.) that if r be one of the n th roots of unity, then $\sqrt[n]{1 - r + rx^n}$ is a periodic function of the n th order. For we shall find

$$\alpha^n x = \sqrt[n]{1 - r^n + r^n x^n},$$

which is $= x$ when $w = n$, since r^n then $= 1$. Consequently,

$$\phi\left(\sqrt[n]{1 - r + r(\phi^{-1}x)^n}\right)$$

is a periodic function of the n th order.

If we take $\alpha x = \sqrt[n]{a + bx^n}$, we shall find

$$\alpha^n x = \sqrt[n]{a \cdot \frac{b^n - 1}{b - 1} + b^n x^n},$$

which is periodic of the n th order, if $b^n = 1$, independently of a .

The preceding cases arise from bx being periodic if b be a root of unity.

(55.) We shall now proceed to the consideration of the third class in (45.), namely, those functions of which the successive functions are algebraical cognates, those which immediately strike us, and from which indeed all others must be derived, being

$$a + bx, \quad \frac{a + bx}{a' + b'x}, \quad ax^b.$$

Calculus of Functions. (56.) It will be convenient to investigate the conditions of convertibility of these several classes. We first examine $a + bx$. In order that $a + bx$ and $p + qx$ may be convertible, we must have

$$a + b(p + qx) = p + q(a + bx),$$

$$\text{or } a + bp = p + aq, \text{ that is, } \frac{a}{b-1} = \frac{p}{q-1}.$$

Let $\frac{a}{b-1} = m$, then $a + bx = b(x + m) - m$, a form

we have already used, all the cognates in which b only is changed being convertible with it. It will always be most convenient to write functions in the form in which they are convertible with their cognates; thus $2x + 3$ should always be written $2(x + 3) - 3$, and $1 - 2x$ should be written $-2\left(x - \frac{1}{2}\right) + \frac{1}{2}$.

(57.) The conditions of convertibility of $\frac{a + bx}{a' + b'x}$ are derived from the equation

$$\frac{a + b \frac{p + qx}{p' + q'x}}{a' + b' \frac{p + qx}{p' + q'x}} = \frac{p + q \frac{a + bx}{a' + b'x}}{p' + q' \frac{a + bx}{a' + b'x}}$$

or

$$ap' + bp = a'p + aq$$

$$aq' = b'p$$

$$a'q' + b'q = b'p' + bq',$$

the third of which is true if the first and second be true; giving, as the conditions of convertibility,

$$\frac{a' - b}{a} = \frac{p' - q}{p} \quad \frac{b'}{a} = \frac{q'}{p}.$$

Let

$$\frac{a' - b}{a} = m \quad \frac{q'}{a} = k;$$

whence

$$\frac{a + bx}{b + am + akx}$$

is convertible with every cognate in which a and b only are changed.

Suppose $a = 1$ (to which it may always be reduced) and we have the simple expression

$$\frac{1 + bx}{b + m + kx}.$$

In which form we shall generally use this expression.

(58.) Similarly, the condition of convertibility of two functions of the form ax^b is that $a^{\frac{1}{b-1}}$ shall be the same in both; and the most convenient form of the function is

$$a^{\frac{1}{b-1}} = m \quad ax^b = \frac{mx^b}{m}$$

(59.) Theorem. When $\phi^n x$ is a cognate of ϕx , and ϕx is put in the form in which some of the constants do not enter into the criterion of convertibility, then the performance of the successive operations alters only the independent constants just mentioned.

This follows from the convertibility of the successive functions; for $\phi^n x$ being convertible with ϕx , or $\phi^n \phi x$ being the same as $\phi \phi^n x$, it follows that every condition of convertibility must exist between $\phi^n x$ and ϕx . Now

VOL. II.

Calculus of Functions. ϕx being ax^b or $\frac{mx^b}{m}$, and $\phi^n x$ being of the form $a'x^{b'}$, or $\frac{m'x^{b'}}{m'}$ and $m = \text{const.}$, being the condition of convertibility, it follows that $m' = m$.

(60.) The successive functions of $a + bx$ and ax^b or $b(x + m) - m$ and $\frac{mx^b}{m}$ are contained in the equations

$$\phi^n x = b^n(x + m) - m$$

$$\phi^n x = \frac{(mx)^b}{m}.$$

(61.) In order to find the successive functions of $\frac{a + bx}{a' + b'x}$ or $\frac{1 + bx}{b + m + kx}$, assume

$$\phi^n x = \frac{1 + b_n x}{b_n + m + kx}$$

Then

$$\begin{aligned} \phi^{n+1} x &= \frac{b_n + b + m + (b_n b + k)x}{b_n b + k + (b_n + b + m)m + (b_n + b + m)kx} \\ &= \frac{1 + \frac{b_n b + k}{b_n + b + m}x}{\frac{b_n b + k}{b_n + b + m} + m + kx} \end{aligned}$$

$$\text{whence } b_{n+1} = \frac{b_n b + k}{b_n + b + m}$$

From this equation the successive functions may be readily formed; but a general integral may be given of the equation between b_n and b_{n+1} .

Assume $b_n = pB_n + q$; and substitute the values of b_n and b_{n+1} in

$$b_{n+1}(b_n + b + m) = b_n b + k,$$

which will give the following equation:

$$B_n B_{n+1} + \frac{q + m + b}{p} B_{n+1} + \frac{q - b}{p} B_n + \frac{q^2 + m q - k}{p^2} = 0$$

$$\text{Assume } \frac{q + m + b}{p} + \frac{q - b}{p} = 0$$

$$\text{and } \frac{q^2 + m q - k}{p^2} = 1$$

whence

$$q = -\frac{m}{2} \quad p^2 = -\left(\frac{m^2}{4} + k\right)$$

and the equation may be reduced to

$$\frac{B_{n+1} - B_n}{1 + B_n B_{n+1}} = -\frac{2p}{2b + m}$$

or

$$\tan^{-1} B_{n+1} - \tan^{-1} B_n = \tan^{-1} \left(-\frac{2p}{2b + m} \right)$$

or

$$\Delta \cdot \tan^{-1} B_n = \tan^{-1} \left(-\frac{2p}{2b + m} \right)$$

Therefore

$$\tan^{-1} B_n = n \tan \left(-\frac{2p}{2b + m} \right) + C$$

and

$$b_n = p \tan \left(n \tan^{-1} \left\{ -\frac{2p}{2b + m} \right\} + C \right) - \frac{m}{2}.$$

2 T

Calculus of
Functions.

The value of C may be determined from $b_1 = b$, which gives $C = \frac{\pi}{2}$, or, all reductions made,

$$b_n = p \cot \left(n \tan^{-1} \frac{2p}{2b+m} \right) - \frac{m}{2}.$$

There are three distinct forms to consider, namely, where p^2 is positive, nothing, and negative. This depends upon whether $m^2 + 4k$ is $-$, 0 , or $+$.

$$\begin{array}{ll} m^2 > -4k & p^2 \text{ is } - \\ m^2 = -4k & p^2 \text{ is } 0 \\ m^2 < -4k & p^2 \text{ is } + \end{array}$$

In the last of the three cases, the expression above given for b_n is the rational form, and can always be reduced to a simple algebraical form; in the first it becomes of an impossible form, trigonometrically speaking, and must be reduced to an exponential form.

By means of the expressions

$$\sqrt{-1} \tan(x\sqrt{-1}) = \frac{1 - e^{2x}}{1 + e^{2x}}$$

$$2\sqrt{-1} \tan^{-1}(x\sqrt{-1}) = \lambda \left(\frac{1-x}{1+x} \right)$$

we find the following transformation for b_n .

Let
$$p^2 = -p^2 = \frac{m^2}{4} + k$$

$$b_n = p' \frac{(2b+m+2p')^n + (2b+m-2p')^n}{(2b+m+2p')^n - (2b+m-2p')^n} - \frac{m}{2}$$

when p^2 or $\frac{m^2}{4} + k = 0$, the term

$$p \cot n \tan^{-1} \frac{2p}{2b+m} \text{ or } \frac{p}{\tan n \tan^{-1} \frac{2p}{2b+m}}$$

becomes

$$\frac{2b+m}{2n},$$

or

$$b_n = \frac{2b - (n-1)m}{2n};$$

or if

$$\phi x = \frac{1+bx}{b+m-\frac{m^2}{4}x}$$

$$\phi^n x = \frac{1 + \frac{2b - (n-1)m}{2n}x}{\frac{2b - (n-1)m}{2n} + m - \frac{m^2}{4}x}$$

(62.) The function $\frac{1+b_n x}{b_n+m+kx}$ is equal to x when

b_n is infinite: this cannot happen in the last-mentioned case except when $n=0$ or $\phi^0 x = x$, which fulfils the condition universally. But in the other two cases, the conditions of a periodic function of the n th order are

$$n \tan^{-1} \frac{2p}{2b+m} = w\pi,$$

where w is a whole number, positive or negative. This gives

$$\frac{2p}{2b+m} = \tan \frac{w\pi}{n} = \sqrt{\frac{1 - \cos \frac{2w\pi}{n}}{1 + \cos \frac{2w\pi}{n}}}$$

from which, by substitution for p , and reduction, is found*

$$k = - \frac{b^2 - 2b(b+m) \cos \frac{2w\pi}{n} + (b+m)^2}{2 \left(1 + \cos \frac{2w\pi}{n} \right)}$$

The relation analogous to this, derived from

$$(2b+m+2p')^n - (2b+m-2p')^n = 0,$$

presents k in an impossible form. It may also be obtained from the above.

(63.) If when $\phi x = \frac{1+bx}{b+m+kx}$, we wish to find $\phi^n x$

more directly, we must solve the equation of differences

$$u_{n+1} = \frac{1+bu_n}{b+m+ku_n} \dots \dots (1)$$

which has been virtually done in integrating

$$u_{n+1} = \frac{k+bu_n}{b+m+u_n} \dots \dots (2)$$

for, write the first in the form

$$u_{n+1} = \frac{\frac{1}{k} + \frac{b}{k}u_n}{\frac{b}{k} + \frac{m}{k} + u_n} \dots \dots (3)$$

the solution of (2), with such a value of C as will make $u_0 = x$, is

$$p \tan \left(\tan^{-1} \frac{2x+m}{2p} - n \tan^{-1} \frac{2p}{2b+m} \right) - \frac{m}{2}.$$

To make this the solution of (3), write $\frac{1}{k}$ for k , $\frac{b}{k}$ for b , and $\frac{m}{k}$ for m , and therefore $\frac{p}{k}$ for p , which will give the following;

$$\phi^n x = \frac{p}{k} \tan \left(\tan^{-1} \frac{2kx+m}{2p} - n \tan^{-1} \frac{2p}{2b+m} \right) - \frac{m}{2}$$

which may be easily reduced to the form

$$\frac{1+b_n x}{b_n+m+kx}.$$

(64.) But the most direct algebraical method is as follows. Let the n th function of

$$\frac{1+bx}{b+m+kx} \text{ be } \frac{A_n+B_n x}{A'_n+B'_n x},$$

substitute the first for x in the second, and after reduction equate the result identically with

$$\frac{A_{n+1}+B_{n+1}x}{A'_{n+1}+B'_{n+1}x},$$

which gives two sets of equations of the forms

$$\begin{array}{l} A_n(b+m) + B_n = A_{n+1} \\ A_n k + B_n b = B_{n+1} \end{array}$$

which give

$$\begin{array}{l} A_{n+1} - (2b+m)A_n + (b^2+bm-k)A_{n-1} = 0 \\ B_n = bA_n - (b^2+bm-k)A_{n-1}. \end{array}$$

* This is the formula cited by Mr. Babbage (*Elem. Tr. Calc. Functions*, p. 5) from a paper by Mr. Horner, in the *Annals of Philosophy*, November, 1817, which we have not seen. We presume the third method we have given is that of Mr. Horner.

Calculus of
Functions.

Calculus of Functions. The solution by the usual method is obvious, and the result is as follows. Let r and r' be the roots of

$$R^2 - (2b + m)R + (b^2 + bm - k) = 0,$$

if those roots be possible. Then

$$\phi^n x = \frac{r^n - r'^n + \{b(r^n - r'^n) - r r' (r^{n-1} - r'^{n-1})\} x}{(b+m)(r^n - r'^n) - r r' (r^{n-1} - r'^{n-1}) + k(r^n - r'^n) x}.$$

If the roots be impossible, assume

$$(b+m)^2 - 2(b+m)b \cos 2\theta + b^2 + 2k(1 + \cos 2\theta) = 0$$

$$h^2 = b^2 + mb - k;$$

then

$$\phi^n x = \frac{\sin n\theta + \{b \sin n\theta - h \sin (n-1)\theta\} x}{(b+m) \sin n\theta - h \sin (n-1)\theta + k \sin n\theta \cdot x}$$

from which the condition of periodicity may be derived as before, and it is only in the latter case that a possible cognate of ϕx can be periodic.

(65.) All the successive functions which have here been treated of may be made to give algebraical and functional inverses, or functions with negative and fractional indices; but, as before observed, we have no reason to imagine that we have thus obtained the most general form of $\phi^n x$ in those cases. Thus, if

$$\phi x = b(x+m) - m \quad \phi^n x = b^n(x+m) - m,$$

we find that the operation $b^{-n}(x+m) - m$ performed

upon $b^n(x+m) + m$ will give x , and that $b^p(x+m) - m$ performed on x , p times, will give $b^n(x+m) - m$.

(66.) The periodic functions are the only cases which at present elude this method, but the difficulty may sometimes be conquered as follows.*

Let $r_1, r_2, r_3, \dots, r_n$ be the n th roots of 1; then

$$r_1^w + r_2^w + r_3^w + \dots + r_n^w$$

= 0 for every value of w , except $w =$ multiple of n , when it is $= n$. If we call the preceding $n R_w$, then only one of the following series

$$R_w, R_{w-1}, R_{w-2}, \dots, R_{w-n+1}$$

is equal to 1, and all the rest to 0. Consequently, if ϕx be a periodic function of the n th order, then

$$\phi^m x = x R_w + \phi x R_{w-1} + \dots + \phi^{n-1} x R_{w-n+1},$$

where $w = (\text{mult. of } n) + m$.

For example, let us try a periodic function of the second order. The roots are 1 and -1 , which gives

$$2 R_w = 1 + (-1)^w \quad w = 2p + m,$$

or the m th function of ϕx is

$$\phi^m x = \phi x \frac{1 + (-1)^{m-1}}{2} + x \frac{1 + (-1)^m}{2}$$

$$= \phi x \frac{1 - (-1)^m}{2} + x \frac{1 + (-1)^m}{2}.$$

If for m we substitute a fraction, we shall find that the preceding equation may or may not be true, according to the form of ϕ . If $\phi x = 1 - x$ and $m = \frac{1}{2}$; then

$$\phi^{\frac{1}{2}} x = \frac{1 - \sqrt{-1}}{2} + \sqrt{-1} x$$

$$\left(\phi^{\frac{1}{2}}\right)^2 x = 1 - x = \phi x.$$

But if $\phi x = \frac{1}{x}$, and $m = \frac{1}{2}$, the preceding is not true.

A reason to suspect such a result we may see as follows. In deducing the various cases hitherto arrived at of

* Sir J. Herschel, *Examp. Calc. Diff.*, sect. xi., p. 137.

$$\phi^n x = \Phi(n, x),$$

we have employed processes which, though only demonstrable, or at least demonstrated, when n is a whole number, are yet general in form, not introducing the condition that n is whole, as part of the evidence of the form of the result. Thus

$$(\phi^m)^n x = \phi^m \phi^m \phi^m \dots \phi^m x$$

is a result of the operations, without reference to the value of m or n ; or, though m and n are understood to be whole numbers, yet no consequence of this understanding affects, or can affect, the passage from any one step to another. In the case immediately preceding, however, the contrary happens; the general expression for $\phi^n x$ cannot be changed into that for $\phi^{n+1} x$ by the substitution of ϕx for x , without direct reference to the whole value of m and its consequences, namely, that $1 - (-1)^m = 0$, or 1 and $1 + (-1)^m = 1$ or 0.

Again, in the preceding cases we arrived at a function of n ; in the present we have introduced an arbitrary function of n . We say arbitrary, because there is an infinite number of methods of accomplishing the same object. Let

$$p = \frac{1 - (-1)^m}{2} \quad q = \frac{1 + (-1)^m}{2}$$

then

$$x^p (\phi x)^q \quad \frac{x^{2p} (\phi x)^{2q}}{p x + q \phi x}, \text{ \&c.}$$

are all forms which become x or ϕx , according as m is even or odd. And, generally,

$$\psi^{-1}(p \psi x + q \psi \phi x)$$

is a representation of $\phi^m x$ ($\phi^2 x = x$), in which, by varying the form of ψ , m itself may be introduced as a constant in an infinite number of different ways.

In the same way we may see that if $\phi^n x = x$,

$$\phi^m x = \psi^{-1}(R_{m-1} \psi x + R_{m-2} \psi \phi x + \dots + R_{m-n} \psi \phi^{n-1} x).$$

The student must not, however, confound this expression with that which has been called the derivative of

$$R_{m-1} x + R_{m-2} \phi x + \dots + R_{m-n} \phi^{n-1} x,$$

which would be

$$\psi^{-1}(R_{m-1} \psi x + R_{m-2} \phi \psi x + \dots + R_{m-n} \phi^{n-1} \psi x).$$

(67.) The equations by means of which the functional inverses of $\phi^m x$ ($\phi^n x = x$) are to be generally found, might be determined as follows. Let $n = 2$, and say we

wish to determine $\phi^{\frac{1}{2}} x$, or to find χx , so that $\phi x = \chi^2 x$. We have, therefore, to find ψ and χ from the following two equations:

$$\psi^{-1}(p \psi x + q \psi \phi x) = \chi x$$

or

$$p \psi x + q \psi \phi x = \psi \chi x,$$

and

$$\chi^2 x = \phi x.$$

What we shall afterwards see of such equations will lead us to suppose that periodic functions have no functional inverses which contain arbitrary functions within the limits of Algebra as defined in (8.)

(68.) But there is a certain class of functional inverses which are identical with the various successive functions of ϕx itself ($\phi^n x = x$). When p is a whole number, we have $\phi^p x = x$, which gives $\phi^p \phi^m x = \phi^{p+m} x = \phi^m x$.

Consequently, if $\phi^{\frac{a}{b}} x$ be $\phi^m x$, where m is a whole num-

Calculus of Functions. ber, or if $\phi^a x$ be $\phi^{mb} x$, it follows that $mb = np + a$, which equation can always be satisfied by whole values of m and p , except only where b and n have a common

measure which a has not. If, then, we suppose $\frac{a}{b}$ to be reduced to its lowest terms, we have the following theorem.

If $\phi^n x = x$, some value or other of $\phi^m x$ is a value of $\phi^{\frac{a}{b}} x$, except only where b and n have a common measure greater than unity.

Thus, if $\phi^6 x = x$, we have a particular case of $\phi^{\frac{1}{3}}$ in ϕ^5 , for $(\phi^5)^3 x = \phi^{15} x = \phi x$. If $\phi^7 x = x$, we have a case of $\phi^{\frac{1}{3}}$ in ϕ^4 , for $(\phi^4)^3 x = \phi^{12} x = \phi^3 x$, &c.

(69.) We shall now stop to consider a most important part of the subject, for which the preceding articles furnish materials, namely, the criterion of impossibility, so far as the same may be established or suspected. We have as yet regarded the functional symbol as one of continued quantity, but the preceding method of representing the successive functions of ϕx ($\phi^n x = x$) has led us to a function discontinuous in value, namely, one which is impossible in value for any fractional value of n , but possible for all whole values of n . And we must either say, that a general expression for $\phi^n x$ is either impossible, or (if we extend our notion of the meaning of the functional form) discontinuous.

We are here in the same situation as in Algebra, when we say that $a - b$ ($a < b$) is either impossible, or (if we extend our notion of quantity) negative. The symbol of the latter term is obtained by performing the operation indicated, as if it were rational; and in this as in other cases, we find that though the symbols of analysis can in no case be made to express the limitations under which operations are possible, or to give warning at the moment of overstepping them, they leave (each in its own way) a mark of impossibility in the result; or, if the impossibility be evaded by extensions of meaning, a mark of negative, imaginary, &c., quantity, as the case may be. We shall, therefore, perform an operation of which we know the result to be impossible, (or, if extension be necessary, discontinuous,) meaning impossible, if we stick to our primitive idea of the functional symbol; discontinuous, if we allow it to include discontinuous functions.

(70.) We have proved (49.) that the derivatives of a periodic function are periodic, and of the same order: we must, therefore, not expect any discriminating symbol if we attempt to express one periodic function as a derivative of another of the same order. In the proposition of (50.) we excluded periodic functions, only because we had then no mode of expressing $\phi^n x$ in general terms. But let us now suppose ϕx and ψx to be two periodic functions of the second order, of which ψx is to be made a derivative of ϕx .

$$\phi^n x = \phi x \frac{1 - (-1)^n}{2} + x \frac{1 + (-1)^n}{2}$$

$$\psi^n y = \psi y \frac{1 - (-1)^n}{2} + y \frac{1 + (-1)^n}{2}.$$

Eliminate n between these two, and remark that at the same time we eliminate altogether $(-1)^n$, the symbol of discontinuity. Write c and c' for $\phi^n x$ and $\psi^n y$, as in (50.) The result is

$$y \phi x - x \psi y = c(y - \psi y) - c'(x - \phi x);$$

Calculus of Functions.

from which y is to be determined in terms of x , and vice versa.

For instance, let $\psi y = \frac{1}{y}$, $\phi x = 1 - x$: which gives

$$y = \frac{-c'(2x-1) + \sqrt{c'(2x-1)^2 - 4(c-x)(1-x-c)}}{2(1-x-c)}$$

$$= \Theta x$$

$$x = \frac{y^2(1-c) - c'y + c}{y^2 - 2c'y + 1} = \Theta^{-1} y$$

$$\frac{1}{x} = \Theta(1 - \Theta^{-1} x)$$

(71.) Suppose we now try (what we know to be impossible) to represent a function which is not periodic in the form of a derivative from one which is periodic. For instance, to determine Θ so that

$$x + 1 = \Theta(1 - \Theta^{-1} x).$$

As before, eliminate n from

$$\phi x \frac{1 - (-1)^n}{2} + x \frac{1 + (-1)^n}{2} = c$$

$$y + n = c',$$

in which the sign of discontinuity is not eliminated with its exponent. This gives

$$\frac{\phi x + x}{2} - \frac{\phi x - x}{2} (-1)^{c'-y} = c;$$

or

$$y = c' - \lambda \left(\frac{\phi x + x - 2c}{\phi x - x} \right)^{\frac{1}{\lambda(-1)}}$$

$$= \Theta x$$

$$y + 1 = \Theta \phi x, \text{ or } x + 1 = \Theta \phi \Theta^{-1} x.$$

In verifying the last equation, remember that logarithms of different signs must be chosen for -1 and

$$\frac{1}{-1}. \text{ The equation } \lambda \left(\frac{1}{x} \right) = -\lambda x, \text{ where}$$

$$\lambda x = \log x + 2m\pi\sqrt{-1}$$

gives relatively to itself

$$\lambda \frac{1}{x} = -\log x - 2m\pi\sqrt{-1}$$

It therefore appears, and will appear, it is easy to see how, that when such an exponent as $\frac{1}{\lambda(-1)}$ occurs, there

has been discontinuity expressed or implied in the previous operations or conditions. And those things which are impossible of continuous functions are not therefore impossible of discontinuous functions: all ordinary reasoning upon functions is based upon principles which are only (as far as has been shown) necessarily true of continuous functions; consequently, conditions which such reasoning proves to be impossible are not necessarily impossible, either of discontinuous functions, or of those which retain the test of their appear-

ance in the process, namely, $\frac{1}{\lambda(-1)}$ as an exponent, or any other.

(72.) This I apprehend to be the answer to the dif-

Calculus of Functions. Calculus of Functions. one sort of discontinuity (at least *not* continuity) as the means of its removal; namely, the employment of $\phi_{-1}x$ in one part of a verification, and of $\phi^{-1}x$ in the other.

It is as follows: if $\phi\left(\frac{1}{x}\right) = c\phi(x)$, it follows that $\phi x = c\phi\left(\frac{1}{x}\right)$, by substituting $\frac{1}{x}$ for x ; whence by common multiplication $1 = c^2$ and $c = +1$ or -1 .

Therefore (and as to functions unaffected with $(\)^{\frac{1}{\lambda(-1)}}$ or an equivalent there can be no doubt) no function can satisfy this condition. Against this it is urged, that

$\left(\frac{1-x}{1+x}\right)^{\frac{\lambda c}{\lambda(-1)}}$ does satisfy the condition: for

$$\frac{1 - \frac{1}{x}}{1 + \frac{1}{x}} = \frac{1-x}{1+x} \times -1$$

$$\left(\frac{1 - \frac{1}{x}}{1 + \frac{1}{x}}\right)^{\frac{\lambda c}{\lambda(-1)}} = \left(\frac{1-x}{1+x}\right)^{\frac{\lambda c}{\lambda(-1)}} \times (-1)^{\frac{\lambda c}{\lambda(-1)}}$$

$$= \left(\frac{1-x}{1+x}\right)^{\frac{\lambda c}{\lambda(-1)}} \times e^{\lambda c} = c \left(\frac{1-x}{1+x}\right)^{\frac{\lambda c}{\lambda(-1)}}$$

Now, though the preceding solution is not obviously discontinuous, (it must be remembered that we are speaking of discontinuity of value, as distinguished from discontinuity of law,) yet its inverse is so: for if

$$ax = \left(\frac{1-x}{1+x}\right)^{\frac{\lambda c}{\lambda(-1)}} \quad a^{-1}x = \frac{1 - (-1)^{\frac{\lambda c}{\lambda(-1)}}}{1 + (-1)^{\frac{\lambda c}{\lambda(-1)}}},$$

which presents rational value only when x is a whole power of c , giving $a^{-1}x = 0$ for all odd powers, and $a^{-1}x = \infty$ for all even powers. And the same may be proved

generally of $(\phi x)^{\frac{1}{\lambda(-1)}}$, the inverse of which is $\phi^{-1}\{(-1)^{\lambda c}\}$,

which will generally present rational values only when x is a whole power of c .

(73.) Our definition of a discontinuous function being that which has possible values for definite possible values of its subject, and impossible for all between, and implying no more than is meant in this definition, we may now show that a *discontinuous* function of a *discontinuous* function may be a *continuous* function.† For instance, the second function of

$$x^{\frac{1}{\lambda(-1)}} \text{ is } x^{\frac{1}{\lambda(-1)^2}} = x^{\frac{1}{\pi^2} \times \text{sq. of any odd No.}}$$

This theorem will show that problems relating to con-

* Observations on the analogy between the Calculus of Functions and other branches of analysis.—Phil. Trans. Read April 17, 1817, p. 18.

† An argument might be drawn from this which would be as rational as, and would set in rather a ludicrous light, a practice which formerly prevailed in the explanation of algebraical terms. If $-(-a) = +a$, because the negation of a negation is an affirmation, surely the *discontinuance* of *discontinuity* has a right to be considered as the commencement of *continuity*.

tinuous functions may find rational solutions among discontinuous functions, and the continuity presumed in the problem may be satisfied.

(74.) What we have here called discontinuity is discontinuity of value, as distinguished from discontinuity of law, and the second may be expressed by means of the first. And the theorem of the last article is, that a discontinuous function (in value) of a discontinuous function (in value) may be continuous in value. Of functions discontinuous in law the same thing is sufficiently obvious. For if ϕx be a function which is ax from $x = a$ to $x = b$, and βx from $x = b$ to $x = c$; then if ψx be another discontinuous function, which is $\gamma a^{-1}x$ from $x = a$ to $x = b$, and $\gamma \beta^{-1}x$ from $x = b$ to $x = c$, we shall have from a to c , $\psi \phi x = \gamma x$. And hence it is a necessary condition that the breach of continuity should take place at the same values of x in both. The latter may also be shown with respect to functions discontinuous in value, it being known that possible functions of possible functions are possible, and that of an impossible function only an impossible function can be possible. For if ϕx be possible only when $x =$ one of $a, b, c, \&c.$, then if ψx be discontinuous, and $\psi \phi x$ continuous, ψ must be impossible where ϕ is impossible.

(75.) We shall now proceed to the expression of any one periodic function as a derivative of any other of the same order. Let ϕx and ψx be the two functions in question, or let $\phi^n x = x$, $\psi^n x = x$. We have then to eliminate m between the equations

$$0 = c + x R_m + \phi x R_{m-1} + \dots + \phi^{n-1} x R_{m-n+1}$$

$$0 = c' + y R_m + \psi y R_{m-1} + \dots + \psi^{n-1} y R_{m-n+1}$$

where

$$n R_m = r_1^m + r_2^m + \dots + r_n^m,$$

and $r_1, r_2, \dots, r_n$ are the roots of $r^n - 1 = 0$.

If r be one of these impossible roots, such that the rest shall be $r^2, r^3, \dots, r^n$, we shall have

$$n R_m = r^m + r^{2m} + \dots + r^{nm};$$

and (writing c and c' for $\frac{c}{n}$ and $\frac{c'}{n}$), the substitution of this in the above equations gives two equations of the form

$$P_0 + P_1 r^m + P_2 r^{2m} + \dots + P_{n-1} r^{(n-1)m} = 0,$$

where

$$P_0 = c + x + \phi x + \dots + \phi^{n-1} x,$$

or

$$c + y + \psi y + \dots + \psi^{n-1} y$$

$$P_1 = x + r^{-1} \phi x + r^{-2} \phi^2 x + \dots + r^{-(n-1)} \phi^{n-1} x$$

$$P_2 = x + r^{-2} \phi x + r^{-4} \phi^2 x + \dots + r^{-2(n-1)} \phi^{n-1} x.$$

&c.

&c.

&c.

If we eliminate r^m from these two equations, in the usual way, remembering that $r^{n+p} = r^p$, we shall have an equation of the form

$$Q_0 + Q_1 r + Q_2 r^2 + \dots + Q_{n-1} r^{n-1} = 0.$$

If we multiply this by r^{n-v} it becomes

$$Q_0 r^{n-v} + Q_1 r^{n-v+1} + \dots + Q_v + Q_{v+1} r + \dots + Q_{n-1} r^{n-v-1} = 0,$$

or

$$Q_v + Q_{v+1} r + \dots + Q_{n-1} r^{n-1} = 0,$$

or these functions $Q_0, \&c.$, must be such that the same change which makes Q_0 become Q_v makes Q_1 become Q_{v+1} , &c. Again, the only admissible change is that which arises from changing x and y into $\phi^m x$ and $\psi^m y$. Hence the form of the final equation is

Calculus of Functions. $\chi(x, y) + r\chi(\phi x, \psi y) + r^2\chi(\phi^2 x, \psi^2 y) + \dots + r^{n-1}\chi(\phi^{n-1} x, \psi^{n-1} y) = 0.$

It is unnecessary to find more than the form; for the preceding process immediately suggests that *any form whatever* of χ will satisfy the conditions. For the object being to obtain $y = \Theta x$ in such a manner that $\psi y = \Theta \phi x$, $\psi^2 y = \Theta \phi^2 x$, &c., the preceding process makes it appear that $\psi y = \Theta \phi x$, &c., might be deduced by the same steps which give $y = \Theta x$. Nor would the particular form derived from the preceding methods be of any use, as it is obtained (66.) from a very limited method of expressing $\phi^m x$ and $\psi^m x$.

The equation in (70.) is a particular case of the preceding result; where $n = 2$ or $r = -1$; being $y\phi x - cy + c'x + (-1)(x\psi y - c\psi y + c'\phi x) = 0$, for which we are therefore at liberty to substitute

$$\chi(x, y) = \chi(\phi x, \psi y).$$

Thus, in the case of (70.), where we make $\frac{1}{x}$ a derivative of $1 - x$, we may, instead of the equation there given, determine y from

$$x + y = 1 - x + \frac{1}{y},$$

or from
$$x\sqrt{y} = \frac{1-x}{\sqrt{y}}, \text{ \&c.,}$$

the last of which gives the most simple value of y , namely, $\frac{1-x}{x}$.

(76.) We now come to the subject of convertible functions generally: that is, of those which satisfy the equation $\phi\psi x = \psi\phi x$. And, in the first place, ϕ^n and ϕ^m are convertible for all values of m and n . When m and n are whole numbers, this follows from the nature of the operation, for $\phi^2\phi^3 x$ signifies $\phi\phi(\phi\phi\phi x)$ or $\phi^5 x$, and $\phi^3\phi^2 x$ signifies $\phi\phi\phi(\phi\phi x)$, which is also $\phi^5 x$. When m and n are negative, we have, by hypothesis, restricted the meaning of $\phi^{-1}x$ to the inverse which is convertible with ϕx , &c. Hence ϕ^{-2} , for example, is convertible with ϕ^{-3} , both being ϕ^{-5} . We shall also restrict the meaning of $\phi^{\frac{1}{n}}$ to those operations of the kind which are convertible with ϕ , that is, if any others shall be found. Hence $\phi^{\frac{1}{3}}\phi^{\frac{1}{2}}x$ is the same as $\phi^{\frac{1}{2}}\phi^{\frac{1}{3}}x$, both being $\phi^{\frac{5}{6}}x$.

We have proved that if ϕ and ψ be convertible functions, all their corresponding derivatives are convertible. The converse of this is true, since the primitive function is itself a derivative of its derivative ($\Theta^{-1}(\Theta\phi\Theta^{-1})\Theta x = \phi x$). But here it must be remembered that if

$$\Theta\phi\Theta^{-1}x = ax, \quad \Theta\psi\Theta^{-1}x = \beta x,$$

and if a and β be convertible, we do not know that more than one of the values of ϕ which satisfy the first equation is convertible with any one of those which satisfy the second. We are not to assume, for instance, if

$$\Theta\phi\Theta^{-1}x = \Theta\psi\Theta^{-1}x,$$

that therefore $\phi x = \psi x$; though this is evidently one of the values which satisfy that equation.

(77.) To find functions which are convertible with a given function ax , take any other function which has another convertible with it, and such that the equation

$$\Theta\beta\Theta^{-1}x = ax$$

Calculus of Functions

can be easily solved. Let γx be the function which is convertible with βx ; then $\Theta\beta\Theta^{-1}x$ and $\Theta\gamma\Theta^{-1}x$, or ax and $\Theta\gamma\Theta^{-1}x$ are convertible. If Θ contain an arbitrary function, an infinite number of solutions may be thus proved, and sometimes obtained.

For instance, $1+x$ and $x+\phi(\cos 2\pi x)$ are evidently convertible. Let

$$\alpha\Theta x = \Theta(1+x),$$

that is, let

$$\alpha^n x = A(n, x),$$

and eliminate n between

$$c' = y + n \text{ and } c = A(n, x),$$

or find

$$y = \Theta x \text{ from } c = A(c' - y, x).$$

Then

$$\Theta(\Theta^{-1}x + \phi \cos(2\pi\Theta^{-1}x))$$

will be convertible with αx . Generally, let ξx be a solution of $\xi ax = \xi x$, and let

$$\beta^n x = B(x, n, c, c' \dots).$$

Let $\Theta\beta\Theta^{-1}x = ax$, as before, then a and β are convertible functions. But if, instead of n, c, c' , we write $\eta\xi x, \zeta\xi x, \kappa\xi x$, &c., η, ζ , and κ being any functions, we find that

$$ax \text{ and } \Theta B(\Theta^{-1}x, \eta\xi x, \zeta\xi x, \kappa\xi x \dots)$$

are convertible. For $\eta\xi x$, &c., are constants with respect to the only change x undergoes in the function ΘB , namely, a change into ax .

(78.) We have already considered the principal convertible functions of Algebra: we shall only observe further that all derivatives of ϕx with respect to Θ are equal to ϕx , if Θ and ϕ be convertible: for in that case $\Theta\phi\Theta^{-1}x = \Theta\Theta^{-1}\phi x = \phi x$.

(79.) If two periodic functions be convertible, and if they be of the m th and n th order, the function compounded of them is periodic, and not of a higher order than the (mn) th. For if

$$\phi^m x = x, \quad \psi^n x = x, \text{ and } \phi\psi x = \psi\phi x,$$

then

$$\begin{aligned} \phi\psi \dots \phi\psi \dots (\text{repeated } mn \text{ times}) &= \phi^{mn}\psi^{mn}x \\ &= \overline{\phi^n}^m \overline{\psi^m}^n x = \overline{\phi^n}^m x = x. \end{aligned}$$

If r and r' be m th and n th roots of 1, then rx and $r'x$ are convertible periodic functions of those orders, and so are $\Theta r\Theta^{-1}x$ and $\Theta r'\Theta^{-1}x$. The function compounded of them is $\Theta r\Theta^{-1}\Theta r'\Theta^{-1}x$, or $\Theta rr'\Theta^{-1}x$, which may easily be shown to be as above.

(80.) There is one class of functions remaining to be noticed, namely, that of functions which are *symmetrical* with respect to two or more letters. A function of x and y is symmetrical with respect to those letters when both enter under precisely the same circumstances, so that an interchange of the two does not affect the value of the function. Such functions are

$$x+y, \quad xy, \quad \frac{x^2+y^2}{x+y}, \quad \sin^{-1}x + \sin^{-1}y.$$

The following are symmetrical functions of x, y , and z ; that is, an interchange of any two of the preceding three does not affect the value of the function.

$$\begin{aligned} x+y+z, \quad xy+yz+zx \\ \sin^{-1}(x+y) + \sin^{-1}(y+z) + \sin^{-1}(z+x). \end{aligned}$$

If a function be symmetrical with respect to x and y , and to y and z , it will be so with respect to x and z ;

Calculus of Functions. for if x may be put in place of y , and z the same, and the corresponding interchanges being made, if no new terms be introduced thereby, then, since every term or factor which contains y is only removed in either case, there are the same terms and factors with respect to x as to z . This will, however, appear more clearly by the following reasoning.

(81.) If we call $x + y = 2p$ and $xy = q^2$, then any function of x and y is a function of p and q . But all unsymmetrical functions are twofold functions of p and q , that is, present double values, according to whether we take one sign or the other for the values of x and y derived from the above equation. For instance, $x^2 + y$ is either

$$(p + \sqrt{p^2 - q^2})^2 + p - \sqrt{p^2 - q^2},$$

or

$$(p - \sqrt{p^2 - q^2})^2 + p - \sqrt{p^2 - q^2}.$$

But in symmetrical functions this cannot be the case; for, since x and y can be interchanged, so can any values we may write for them. The characteristic of a symmetrical function is therefore that it has no more values when considered as a function of p and q than it has as a function of x and y .

(82.) Let there be a function which is symmetrical with respect to x and y , and is also a function of z . Consequently, it can be represented by

$$\phi(x + y, xy, z).$$

Let it also be symmetrical with respect to x and z , so that x and z may be interchanged in the preceding, which, as before observed, is unambiguous in value. That is,

$$\phi(x + y, xy, z) = \phi(z + y, zy, x),$$

which last is the form of a function symmetrical with respect to z and y .

(83.) A symmetrical function of x , y , and z can be represented by an unambiguous form of

$$\phi(x + y + z, xy + yz + zx, xyz),$$

and so on.

(84.) A function is symmetrical with respect to any two of n quantities, when it is symmetrical with respect to $(n - 1)$ pairs out of the $\frac{1}{2}n(n - 1)$ which can be

taken, provided every letter be contained once. Take five quantities, a, b, c, d , and e , and let $(ab, bc; ac)$ be the abbreviation of the deduction of the symmetry of the function with respect to a and c from that with respect to a and b and b and c . Let ab, bc, cd, de , be the pairs which enter into the hypothesis

$$\begin{array}{ll} ab, bc; ac & bc, cd; bd \\ ac, cd; ad & bd, de; be \\ ad, de; ae & cd, de; ce \end{array}$$

and there are but ten pairs from the five quantities a, b, c, d, e . If the pairs chosen had been ab, ac, bd, ce , we should have had

$$\begin{array}{ll} ab, bd; ad & ba, ae; be \\ ba, ac; bc & cb, bd; cd \\ ac, ce; ae & da, ae; da \end{array}$$

(85.) If $\phi^n x = x$, any symmetrical function of $x, \phi x, \phi^2 x, \dots, \phi^{n-1} x$ is constant when $\phi^n x$ is changed into $\phi^{n-1} x$, $\phi^{n-1} x$ into $\phi^{n-2} x$, &c. For, on account of the recurrence of $x, \phi x$, &c., in $\phi^n x, \phi^{n+1} x$, &c., this change amounts to a mere interchange of the subjects of the function. For instance, if $\phi^3 x = x$, then writing $\phi^2 x$ for x , in

$$x + \phi x + \phi^2 x + x \cdot \phi x \cdot \phi^2 x,$$

gives

$$\phi x + \phi^2 x + x + \phi x \cdot \phi^2 x \cdot x.$$

(86.) If we investigate the conditions under which

symm. function $(a_1 x, a_2 x, a_3 x, \dots, a_n x)$

may remain constant when x is changed into ϕx , we shall find

$$a_2 \phi x = a_1 x \quad a_3 \phi x = a_2 x \dots a_1 \phi x = a_n x,$$

or

$$a_n x = a_1 \phi x = a_2 \phi^2 x = \dots = a \phi^n x,$$

or

$$a_n x = a_n \phi^n x.$$

Consequently, either $\phi^n x = x$, in which case the function may be reduced to

symm. function of $(a_1 x, a_1 \phi x, a_1 \phi^2 x, \dots, a_1 \phi^{n-1} x)$,

or ϕx must be the n th functional inverse of one of the invertible algebraical inverses of $a_n x$.

(87.) Any function of the form

$$\psi x \times \text{symm. function of } (x, \phi x, \dots, \phi^{n-1} x)$$

is periodical in its values when x is changed into $\phi x, \phi^2 x$, &c., in succession, if $\phi^n x = x$.

(88.) But when $\phi^n x = x$, a more general species of symmetry will satisfy the equation $\psi \phi x = \psi x$. It is sufficient to take such a function of $x, \phi x, \phi^2 x, \dots, \phi^{n-1} x$, as will remain the same when x is changed into $\phi x, \phi x$ into $\phi^2 x, \dots, \phi^{n-1} x$ into $\phi^n x$ or x , all at once. For instance, if $\phi^3 x = x$,

$$\frac{x}{\phi x} + \frac{\phi x}{\phi^2 x} + \frac{\phi^2 x}{\phi^3 x}$$

$$x^2 \phi x + (\phi x)^2 \phi^2 x + (\phi^2 x)^2 x$$

do not change when ϕx is substituted throughout instead of x . But a simple interchange of ϕx and x would alter either of the preceding functions.

(89.) Hence it appears that a solution of $\psi \phi x = \psi x$ is not necessarily a function of the coefficients of the equation whose roots are $x, \phi x, \phi^2 x, \dots, \phi^{n-1} x$.

If we denote by $\chi(a, b, c)$ any function of a, b , and c , and by $\chi(b, c, a)$ a similar function, in which a has become b , b has become c , and c has become a , the general form of the solution of $\psi \phi x = \psi x$ where $\phi^3 x = x$ is

$$\psi x = \chi(x, \phi x, \phi^2 x) + \chi(\phi x, \phi^2 x, x) + \chi(\phi^2 x, x, \phi x),$$

or any other properly symmetrical function of the three forms of χ .

(90.) Here it is to be observed, that when ψx represents a function of $x, \phi x, \phi^2 x, \dots, \phi^{n-1} x$, which satisfies the equation $\psi \phi x = \psi x$, whence we have $\psi \phi^2 x = \psi \phi x$, &c., and

$$\psi x = \frac{1}{n} \{ \psi x + \psi \phi x + \dots + \psi \phi^{n-1} x \} \dots (A)$$

in which all interchanges would seem possible: this is nevertheless not necessarily the case. If ψx were a function of x only, and not identical with $\psi \phi x$, then no interchange would alter the form of the second side of (A). But this is not always the case where ψx is also a function of ϕx , &c., and never when $\psi \phi x = \psi x$, unless where the interchanges in question can already be made in ψx by itself, without altering its form.*

* The late M. Abel, whose talents have most deservedly secured a reputation almost unequalled, considering the age at which he died, has (Crelle's Journal, vol. iv.) overlooked this distinction, and in consequence has inferred, that whenever two roots of an irreducible equation are connected by a known and rational relation,

Calculus of
Functions.

(91.) The two species of symmetry described in (80.) and (88.) might be distinguished by the names of *disjunctive* and *periodical*, which, for want of better, we shall adopt. Thus

$$ab + bc + ca$$

is disjunctively symmetrical with respect to a , b , and c ; while

$$ab^2 + bc^2 + ca^2$$

is periodically symmetrical. All disjunctively symmetrical functions are periodically so, but the converse is not true.

(92.) In all cases, a particular solution of $\phi a^2 x = \phi x$ may be made to give a general solution of $\phi a x = \phi x$. Let ωx be the particular solution, say of $\phi a^2 x = \phi x$, then any periodically symmetrical function of ωx , $\omega a x$, and $\omega a^2 x$ being taken, for instance,

$$\frac{\omega x}{\omega a x} + \frac{\omega a x}{\omega a^2 x} + \frac{\omega a^2 x}{\omega x},$$

any arbitrary function of this is a solution of $\phi a x = \phi x$.

(93.) Mr. Babbage has proposed to let $\bar{\phi}(x, y)$ stand for a function which is symmetrical with respect to x and y ; $\phi(\bar{x}, \bar{y}, z)$ to stand for a function of x , y , and z , which is symmetrical with respect to x and y only. But as we shall not in this Treatise have sufficient occasion to use symmetrical functions in very complicated operations, we prefer some circumlocution to the substitution of a purely arbitrary symbol for a *derived* notion. The future progress of the Science will doubtless, as in all cases which have hitherto occurred, suggest the proper method of representing a symmetrical function.

We shall be continually obliged to mention functions which are constant under ax for x , (as we may call it,) that is, which do not change form when ax is written for x . These we shall always denote by ξ ; that is, ξax means ξx , a function which satisfies the condition $\xi x = \xi ax$. Thus, $\cos 2\pi x$ is a particular case of $\xi(x+1)$.

Most of the symmetrical functions which we shall have occasion to use are those of $x, \phi x, \dots, \phi^{n-1}x$, where $\phi^n x = x$; and the symmetry need be only periodical (91.) This is then a particular case of $\xi \phi x$ (88.); and though there may be other values of ξ (possibly) which may satisfy $\xi \phi x = \xi x$, and which are not symmetrical, yet as our assumption of a symmetrical function will always arise from our not knowing what these other solutions may be, and as the other solutions would do as well, if they could be found, we shall use $\xi \phi x$ as the representation of a symmetrical function of $x, \phi x, \dots, \phi^{n-1}x$, when $\phi^n x = x$.

(94.) We now come to the various classes of functional equations which it may be necessary to consider. If there be any number of quantities, x, y, z , &c., between which a functional relation exists, the questions which may be asked are as follows:

1. Where all the functional forms are known, what functional relations must exist between x, y, z , &c., in order that the equation may be satisfied? This embraces the whole of common Algebra: for instance, the solution of

the equation admits of solution by means of equations of a lower degree. His demonstration, however, from what has been here said, cannot stand, unless any solution of $\psi \phi x = \phi x$ can be expressed in terms of the coefficients of the equation whose roots are $x, \phi x, \dots, \phi^{n-1}x$, without solving the equation itself. This, we believe, has never been done.

$$x^2 - xy + ay^2 = 0$$

is a particular case of the following,

$$F(x, y, \phi y, \psi x, \&c.) = 0,$$

where F, ϕ, ψ , &c. are known forms; what relation does the preceding require to exist between y and x ?

2. Where the forms which enter into the equation are unknown, and it is required to satisfy the equation independently of any relations between x, y, z , &c. For instance,

$$\phi x + \phi y = \phi(x + y)$$

occurs in various branches of Mathematics, where x and y are to be independent. The solution (it is the most general) is $\phi x = mx$, where m is independent of x and y .

3. Where x, y, z , &c. are related in a given manner, and one or more of the functional forms in the equation are to be found so as to satisfy it. For instance, if in the last equation, $y = x + 1$, and we therefore require to solve

$$\phi(x) + \phi(x + 1) = \phi(2x + 1).$$

Here cx is a solution as before: but it is a more general solution in one sense than is necessary, though not the most general in another respect. Properly speaking, this is the solution of

$$\phi x + \phi y = \phi(x + y),$$

where y is independent of x , and c retains its value, whatever y may be when x is changed into y or into $x + y$. But the last equation but one only requires that c should remain unchanged when x is changed into $x + 1$ or $2x + 1$; and if ξx be such a function, $x \times \xi x$ satisfies the equation: for

$$\begin{aligned} x \xi x + (x + 1) \xi(x + 1) &= x \xi x + (x + 1) \xi x \\ &= (2x + 1) \xi x = (2x + 1) \xi(2x + 1), \end{aligned}$$

because

$$\xi x = \xi(x + 1) = \xi(2x + 1).$$

(95.) The third case is the one to which this Treatise is devoted: but the second is a particular branch of the subject which deserves some consideration.

If we take an equation, such as

$$\phi x - \phi(y + 1) = \phi x \times \phi y,$$

in which x and y do not enter symmetrically, it is often easy to prove that no continuous function of x or y will satisfy it. In the preceding instance, let us, for the present, write m for ϕx , which gives

$$\phi(y + 1) = m(1 - \phi y).$$

Of this equation it can be shown, that if ωy be any solution, and $\omega y + \psi y$ the most general solution, ψy can be found from another equation. For we have

$$\omega(y + 1) = m(1 - \omega y),$$

which, subtracted from the preceding, gives

$$\phi(y + 1) - \omega(y + 1) = -m(\phi y - \omega y)$$

or

$$\psi(y + 1) = -m\psi y.$$

Now $\frac{m}{1+m}$ is a particular solution of the equation;

therefore $\frac{m}{1+m} + \psi y$ is the general solution, which

must, if it is to be independent of x , be independent of

m . That is, ψy must have the form $-\frac{m}{1+m} + \chi y$,

where χy is independent of m . In this form, ψy cannot

Calculus of
Functions.

Calculus of
Functions.

be found, and hence $\frac{m}{1+m}$ or $\frac{\phi x}{1+\phi x}$ independent of

x , is the most general solution of the first-mentioned equation. Hence ϕx must be a constant, or the first equation can only be solved by $\phi x = c$, which gives

$$c - c = c \times c, \text{ or } c = 0.$$

(96.) The only remaining case is where x and y enter symmetrically, which may be subdivided again into cases reducible to $Fx = Fy$, and those which are not so reducible. An instance of the first is

$$\phi x + \phi y = \phi(2x) + \phi(2y).$$

Here the change of y into x does not alter the equation, which is moreover immediately reducible to

$$\phi x - \phi(2x) = \phi y - \phi(2y),$$

the only solution of which is

$$\phi x - \phi 2x = \text{a constant},$$

for any other solution gives a relation between x and y . This case then is reducible to the third mentioned in (94.)

But if we take such a relation as

$$\phi x + \phi y = \phi(2x + 2y),$$

which is not reducible to the form $Fy = Fx$, we know that the solutions of this equation must be contained among those of

$$\phi x + p = \phi(2x + q),$$

being such among the solutions of the latter as satisfy the additional conditions

$$q = 2y \quad p = \phi(2y) \quad \frac{d}{dy} \phi x = 0.$$

But all that precedes relates to continuous functions only. We may not (69.) assume any of the conclusions drawn from continuous forms to be true of those which are discontinuous.

(97.) Several cases, however, of the last-mentioned forms admit of solutions by common methods. Such are

$$\phi x + \phi y = \phi(x + y),$$

from which are derived

$$\phi x + \phi y = \phi x \times \phi y$$

$$\phi x + \phi y = \phi(xy)$$

$$\phi x \times \phi y = \phi(x + y)$$

$$\phi x \times \phi y = \phi(xy)$$

and various others.

The use of the Calculus of Functions in regard to these is to show that the obvious algebraical form which satisfies them is also the *most general of continuous functions*. The following process may be applied to all the preceding.

Let $\phi x_1 + \phi x_2 = \phi(x_1 + x_2)$; for x_2 write $x_2 + x_2$; then

$$\phi x_1 + \phi(x_2 + x_2) = \phi(x_1 + x_2 + x_2),$$

or

$$\phi x_1 + \phi x_2 + \phi x_2 = \phi(x_1 + x_2 + x_2),$$

or, generally,

$$\Sigma \phi x = \phi(\Sigma x).$$

Hence

$$n \phi x = \phi n x,$$

where n is any whole number. Let $my = nx$, n being a whole number, then

$$\phi my = \phi nx, \text{ or } m \phi y = n \phi x;$$

VOL. II.

Calculus of
Functions.

or $\phi y = \frac{n}{m} \phi x$, that is $\phi\left(\frac{n}{m}x\right) = \frac{n}{m} \phi x$;

whence $\phi nx = n \phi x$ is true when n is fractional. Let $x_1 + x_2 = 0$, whence by the original equation

$$\phi(-x_1) = -\phi x_1,$$

or

$$\phi(-nx_1) = -\phi(nx_1) = -n \phi x,$$

or $\phi nx = n \phi x$ is true when n is negative. Whence in the equation $\phi nx = n \phi x$ the value of n is universal. Let $nx = y$, then

$$\phi y = \frac{y}{x} \phi x, \text{ or } \frac{\phi y}{y} = \frac{\phi x}{x};$$

whence $\phi y = cy$.

The following theorems, which may be easily proved, contain the preceding demonstration.

1. If α be such a function that its inversion with respect to ϕx substitutes $\frac{1}{n}$ for n , then the equation $\phi nx = \alpha(\phi x, n)$ is true for fractional values of n , if it be true for whole values. Such are $n \phi x, \overline{\phi x}^n$.

2. If α be such a function that its inversion with respect to ϕx changes n into $-n$, then $\phi(x+n) = \alpha(\phi x, n)$ is true for negative values of n , if it be true for positive values. Such is $\phi x + n$.

(98.) The general functional equation containing only one unknown function of one subject may be put under the following form :

$$F(x, \phi x, \phi \alpha x, \phi \beta x, \dots) = 0,$$

where F, α, β , &c., are known forms, and ϕ is an unknown form to be so determined as to satisfy the equation. In almost every case, it will be necessary to suppose a particular solution found, either of the equation itself, or of one connected with it, in such a way that $\psi \alpha x, \psi \beta x$, &c. all enter into it. This, at first sight, appears hardly to be a real solution, but only the reduction of the solution to that of some particular case. But a moment's recollection will show that precisely the same thing takes place in Algebra. For instance, $x^2 + ax = b$ is not solved, except by reduction to the more simple form $y^2 = b$, for which there are no methods of further reduction in Algebra, independent of these which Arithmetic applies to every particular value of b .

For $x = (b)^{\frac{1}{2}}$ is not a solution, but a conventional representation of a solution, being, by definition, nothing more than the solution of $y^2 = b$. Similarly, every equation of the first degree is reduced to $ax = b$, of

which $\frac{b}{a}$ is not a solution, but a representation of a solution.

Let us suppose a particular solution found, and let it be

$$\psi x = \varpi(x, a, b, c, \dots),$$

where a, b, c , &c. are arbitrary constants. A general solution* may then be found, if a function of x can be found which does not change upon the substitution of $\alpha x, \beta x, \dots$ respectively for x . For in that case, if the function be called $\xi \alpha, \xi \beta, \dots, x$, the following values may be substituted for $a, b, c, \dots$:

$$a = \theta \xi x \quad b = \theta' \xi x \quad c = \theta'' \xi x \quad \&c.,$$

* Whether the most general or no is not known. By a general solution we always mean one which admits an indefinite number of forms.

Calculus of Functions. in which $\theta, \theta', \theta'', \dots$ may be any functions whatever, with a limitation presently to be noticed. For in that case, $a, b, c, \dots$ are constant under every change which can take place in verifying the equation $F = 0$ by means of $\psi = \omega$. For instance,

$$\phi(x) + \phi(-x) = x^2$$

is evidently satisfied by $\phi x = \frac{x^2}{2} + cx$; but in place of c may be written any function which contains only even powers of x , or $\xi(-x)$, giving the solution $\phi x = \frac{x^2}{2} + x\xi(-x)$.

(99.) The limitation alluded to above is the following: $\theta \xi x, \theta' \xi x, \&c.$ must preserve the property of unchangeability under x into $\alpha x, x$ into $\beta x, \&c.$, that is, $\theta, \theta', \&c.$ must not involve any operation inverse to ξ . For instance, θx must not be $x + \xi^{-1}x$; for in that case $\theta \xi x$ is $\xi x + x$, which becomes $\xi x + \alpha x$ when x is changed into αx . Thus, in the integration of the equation of differences, $u_{n+1} = v_n$ or $u_n = f(\cos 2\pi n)$, $f x$ may not be $x + \alpha \cos^{-1}x$, for $f \cos 2\pi n$ then becomes $\cos 2\pi n + \alpha(2\pi n)$, and may change when n is changed into $(n+1)$.

(100.) The method of Laplace corresponding to the method given in (46.) is as follows. Let the equation be

$$F(x, \phi \alpha x, \phi \beta x) = 0,$$

where F, α , and β are known forms, and ϕ is to be found. Assume

$$u_x = \alpha x \quad u_{x+1} = \beta x.$$

By elimination from which we obtain

$$u_{x+1} = \beta \alpha^{-1} u_x,$$

or u_{x+1} is a known function of u_x , giving a common equation of differences. If this can be integrated, suppose it done, either in the common form

$$u_x = f(z, C),$$

or in the more general form

$$u_x = f(z, \cos 2\pi z).$$

Next, assume

$$\phi(u_x) = v_x \quad \phi(u_{x+1}) = v_{x+1},$$

which makes the original equation become

$$F(\alpha^{-1} u_x, v_x, v_{x+1}),$$

another equation of differences, which, if it can be integrated, gives

$$v_x = F_1(u_x, \cos 2\pi z),$$

or

$$\phi \alpha x = F_1 x,$$

whence

$$\phi x = F_1 \alpha^{-1} x.$$

For further extensions of this method, see the *Memoirs of the Analytical Society*, p. 98, &c.

(101.) We may exemplify this method hereafter; at present we return to our first method, and observe that we have reduced the solution of a functional equation,

1. To finding a particular solution which contains at least one arbitrary constant.

2. To finding the function which is constant with respect to the equation; that is, which is not changed by changing x into αx , into βx , &c., $\alpha x, \beta x, \&c.$ being all the forms which occur.

For the first, no general process can be given; we

proceed to ascertain how far we can fulfil the second condition. Calculus of Functions.

(102.) And first we propose the equation

$$\phi \alpha x = \phi x,$$

the solution of which, when found, we have agreed to call $\xi \alpha x$. This is evidently a particular case of

$$\phi \alpha x = \beta \phi x,$$

already solved in (50.) Here $\beta x = x$, and the two equations between which n must be eliminated appear to be

$$\alpha^n x = c \quad y = c',$$

from which n cannot be eliminated, because it does not appear in the second.

But, instead of c and c' , we are at liberty to write any functions of n which do not change on changing n into $n+1$, which gives

$$\alpha^n x = \mu \cos 2\pi n \quad y = \nu \cos 2\pi n.$$

Let us suppose these equations give

$$n = Ax \quad n = By;$$

then, by substituting αx for x in the original equations, we obtain

$$n = A \alpha x \quad n = B y,$$

and the fundamental relation is preserved, namely, that a change of n into $n+1$ is equivalent to a change of x into αx . Hence we have

$$y = B^{-1} A x \quad y = B^{-1} A \alpha x,$$

or

$$\xi \alpha x = B^{-1} A x.$$

It might appear that Ax itself satisfies the conditions: but the reasoning of (50.) is based upon the theorem, that in the result of elimination it matters not whether the quantity eliminated were constant or variable; it must be remembered that $n = Ax$ and $n = A \alpha x$ are not both true equations; but that the second set of equations should be

$$n - 1 = A \alpha x \quad n - 1 = B y$$

for

$$\alpha^{n-1}(\alpha x) = \mu \cos 2\pi(n-1).$$

Let $\mu \cos 2\pi n = c$; then, since $y = \nu \cos 2\pi n$, we have the following theorems.

1. If $\alpha^n x = c$, the value of n (or Ax) is a function of x , which satisfies the equation

$$A \alpha x = Ax - 1.$$

2. A very general value of $\xi \alpha x$ is contained in

$$\xi \alpha x = \nu \cos 2\pi A x,$$

where ν is any function which does not invert the cosine: but much more general values, containing, it may be supposed, many transcendents which Ax cannot now express, may be obtained by using

$$\alpha^n x = \mu \cos 2\pi n \quad \text{instead of} \quad \alpha^n x = c.$$

(103.) The function c^{-Ax} is a particular solution of

$$\psi \alpha x = c \psi x,$$

and a particular solution of

$$\psi \alpha x = c' \psi x$$

can be deduced from it, in the form

$$\psi x = c^{-\frac{\lambda \alpha' Ax}{\lambda c}}.$$

Also the function $-cAx$ is a particular solution of

$$\psi \alpha x = \psi x + c,$$

Calculus of Functions.

α^{-Ax} of $\psi \alpha x = (\psi x)^c$.

And in this way a large number of forms may be found with known particular solutions. But we proceed with the investigation of the properties of A .

(104.) Where a name is necessary, we shall call Ax the *exponential inverse* of αx .^{*} If $\alpha_1 x$ be a derivative of αx with respect to Θ , and $A_1 x$ the value of n derived from $\alpha_1 x = c$; then $A_1 x = A \Theta^{-1} x$. For if $\alpha_1 x = \Theta \alpha \Theta^{-1} x$, we have

$$\alpha_1 x = \Theta \alpha \Theta^{-1} x = c;$$

or, writing c for $\Theta^{-1} c$ we find

$$\alpha^n \Theta^{-1} x = c \quad n = A \Theta^{-1} x = A_1 x,$$

from which new classes of particular solutions may be deduced.

(105.) If, instead of αx , we take $\alpha^m x$, we find from the same process $(\alpha^m)^n x = c$, or $m n = A x$; that is,

$$n = \frac{1}{m} A x.$$

Thus of

$$\psi \alpha^m x = \psi x - 1,$$

a particular solution is $\frac{1}{m} A x$. This may be verified, for since

$$A \alpha x = A x - 1,$$

we have

$$A \alpha^2 x = A \alpha x - 1 = A x - 2, \text{ \&c.,}$$

whence

$$A \alpha^m x = A x - m,$$

or

$$A_m \alpha^m x = A_m x - 1, \text{ where } A_m x = \frac{A x}{m}.$$

This holds also where m is a negative whole number: for

$$A \alpha x = A x - 1,$$

we have

$$A \alpha^{-1} x = A x + 1$$

$$A \alpha^{-m} x = A x + m,$$

or

$$A_m \alpha^{-m} x = A_m x - 1, \text{ where } A_m x = -\frac{A x}{m}.$$

But for $m = 0$ we find $A x = \infty$, as might be expected for a solution of

$$A x = A x - 1.$$

That the preceding will also hold when m is fractional may be inferred in all those cases in which the form of $\alpha^n x$ remains true when n is fractional.

(106.) To apply the preceding method, let us take the function $a + b x$, reduced to the form $b(x + m) - m$, in which case it is a derivative of $b x$, being $\Theta b \Theta^{-1} x$ where $\Theta x = x - m$.[†] Let $\alpha x = b x$, which gives $\alpha^n x = b^n x = c$, or

$$n = A x = \frac{\lambda c - \lambda x}{\lambda b} = \frac{c - \lambda x}{\lambda b},$$

changing the form of the constant. Hence

$$\xi b x = \theta \cos 2\pi \frac{c - \lambda x}{\lambda b},$$

* The reader may, as in the case of the derivative, supply any names he likes better. It is important to observe that, in finding ξx , $A x$ may stand for the solution of $A \alpha x = A x \pm p$, where p is any whole number.

† The analogy between functional symbols and products is such that a factor may occupy the place of, and be considered as, a functional symbol.

or, which is the same form, (if the cosine be expanded, and the specific form of θ changed,) Calculus of Functions.

$$\xi b x = \theta \cos 2\pi \frac{\lambda x}{\lambda b},$$

where θ is any form which does not invert the cosine. Again, the exponential inverse of $b(x + m) - m$ is

$$A \Theta^{-1} x, \text{ or } \frac{c - \lambda(x + m)}{\lambda b}; \text{ whence, as before,}$$

$$\xi(b(x + m) - m) = \theta \cos 2\pi \frac{\lambda(x + m)}{\lambda b},$$

or

$$\xi(a + b x) = \theta \cos 2\pi \frac{\lambda(a + b x - x)}{\lambda b}.$$

When $b = 1$, there is an indication of a change of form. In fact, the preceding process fails by the reduction of $\Theta b \Theta^{-1} x$ to x . But if $\alpha x = a + x$, we have $\alpha^n x =$

$$x + n a = c \text{ and } A x = \frac{c - x}{a}. \text{ We have then}$$

$$\xi(a + x) = \theta \cos 2\pi \frac{x}{a}.$$

(107.) Applying the same process to αx^b in the form $\frac{m x^b}{m}$, which is a derivative of $x^b \left(\Theta x = \frac{x}{m} \right)$, we find, if

$$\alpha x = x^b \quad A x = \frac{c - \lambda^2 x}{\lambda b}$$

$$\xi(x^b) = \theta \cos 2\pi \frac{\lambda^2 x}{\lambda b},$$

where $\lambda^2 x$ denotes $\lambda \lambda x$, the logarithm of the logarithm of x .

$$\xi\left(\frac{(m x)^b}{m}\right) = \theta \cos 2\pi \frac{\lambda^2 m x}{\lambda b}$$

$$\xi(a x^b) = \theta \cos 2\pi \frac{\lambda^2 a^{\frac{1}{b}-1} x}{\lambda b}.$$

This fails when $b = 1$, in which case a similar process will give

$$\xi(a x) = \theta \cos 2\pi \frac{\lambda x}{\lambda a}.$$

(108.) The function $\frac{a + b x}{a' + b' x}$, when put in the form $\frac{1 + b x}{b + m + k x}$ (57.), does not readily appear as the derivative of a more simple function of the same kind; but its exponential inverse may be directly found from the expression given in (64.) for its n th function. The most convenient value of c is zero, for the mere purpose of finding a value of $A x$; as appears from the preceding instances. We have, however, retained it hitherto, as solutions with an arbitrary constant are frequently necessary. But in the present case, let us make

$$\alpha x = \frac{a + b x}{a' + b' x} \quad \alpha^n x = 0,$$

which gives (64.)

$$a(r^n - r'^n) + \{b(r^n - r'^n) - r r' (r^{n-1} - r'^{n-1})\} x = 0,$$

from which we obtain, by dividing by r'^n and deducing the value of $\left(\frac{r}{r'}\right)^n$,

Calculus of
Functions.

$$n = \frac{\lambda(a+bx-rx) - \lambda(a+bx-r'x)}{\lambda r - \lambda r'} = Ax,$$

whence we have (r and r' being the roots of

$$R^2 - (a'+b)R + (a'b - ab') = 0)$$

$$\xi \left\{ \frac{a+bx}{a'+b'x} \right\} = \theta \cos 2\pi \lambda \left\{ \frac{a+bx-rx}{a+bx-r'x} \right\}^{\frac{1}{\lambda r - \lambda r'}}.$$

This expression fails in the case already noticed, in which the two roots of the preceding equation are equal, or in which

$$\frac{a+bx}{a'+b'x} \text{ takes the form } \frac{1+bx}{b+m-\frac{1}{4}m^2x}.$$

We might obtain Ax in this case from the expression in (61.); but by differentiating the numerator and denominator of the first expression for Ax in this article with respect to r , in the usual manner, we find, since r must be $\frac{1}{2}(a'+b)$,

$$Ax = -\frac{rx}{a+bx-rx} = \frac{(a'+b)x}{(a'-b)x-2a'},$$

whence

$$\xi \left(\frac{a+bx}{a'+b'x} \right) = \theta \cos 2\pi \frac{(a'+b)x}{(a'-b)x-2a'}$$

$$\xi \left(\frac{1+bx}{b+m-\frac{1}{4}m^2x} \right) = \theta \cos 2\pi \frac{(2b+m)x}{mx-2}.$$

(109.) In (104.) is proved the following theorem. If Ax be a solution of

$$A\alpha x = Ax \pm \text{wh. no.}$$

then

$$\xi(f\alpha f^{-1}x) = \theta \cos 2\pi A f^{-1}x.$$

Hence the determination of $\xi\psi x$ is reduced in all cases to the finding of a particular solution of

$$\psi x = f\alpha f^{-1}x, \text{ or } \psi fx = f\alpha x.$$

Where αx is one of the fundamental forms already noticed, or any other in which n can be found from the equation

$$\alpha^n x = \text{function}(n, x) = 0.$$

This differs from the theorem in (102.), inasmuch as it is not here necessary to determine $\psi^n x$.

(110.) We may moreover observe that the finding of the n th function by means of equations of differences may be more easily done by a similar method, and that, generally speaking, the circumstances which facilitate the integration of $u_{n+1} = \phi(u_n)$ are derived from the expressibility of ϕx in the form $f\alpha f^{-1}x$. For instance, in the case of $\phi x = 2x^2 - 1$ we have evidently $\phi x = \cos 2 \cos^{-1}x$, whence $\phi^n x = \cos 2^n \cos^{-1}x$, from which the expression for $\phi^n x$ in a preceding article may easily be deduced.

(111.) We shall now apply what has preceded to

$$a+bx+cx^2 = f\alpha f^{-1}x.$$

If we assume

$$\alpha x = g+hx^2 \quad fx = p+qx,$$

whence

$$f^{-1}x = \frac{x-p}{q},$$

we find that

$$a+bfx+cf(fx)^2 = f\alpha x$$

is satisfied by one relation only between g and h , namely,

$$gh = \frac{4ac - b^2 + 2b}{4}$$

if at the same time

$$p = -\frac{b}{2c} \quad q = \frac{h}{c}.$$

It therefore remains to ascertain $\alpha^n x$. If, as before, we assume $\alpha_n x = u_n$, we find

$$u_{n+1} = g + hu_n^2,$$

an equation which we are not aware has been or can be integrated, except in the case of

$$gh = 0, \text{ or } -2.$$

If we assume

$$g = 0 \quad h = 1,$$

we find

$$u_n = c^{2^n},$$

or

$$\alpha x = x^2 \quad \alpha^n x = x^{2^n};$$

from which we find that if

$$\phi x = a+bx+cx^2 \quad c = \frac{b^2-2b}{4a}$$

$$\alpha x = x^2 \quad fx = -\frac{b}{2c} + \frac{x}{c} \quad f^{-1}x = \frac{2cx+b}{2}$$

$$\phi x = f\alpha f^{-1}x$$

$$\phi^n x = f\alpha^n f^{-1}x = -\frac{b}{2c} + \frac{1}{c} \left\{ \frac{2cx+b}{2} \right\}^{2^n}$$

$$\xi \phi x = \theta \cos 2\pi \frac{\lambda^2 \{cx + \frac{1}{2}b\}}{\lambda 2}$$

If we assume

$$g = -2 \quad h = 1,$$

or

$$\alpha x = x^2 - 2 \quad u_{n+1} = u_n^2 - 2,$$

or

$$u_n = P^{2^n} + P^{-2^n},$$

where

$$P + \frac{1}{P} = x,$$

we find that if

$$b^2 - 2b + 8 - 4ac = 0$$

$$\phi x = a+bx+cx^2$$

$$\phi^n x = f \left\{ \left(\frac{f^{-1}x + \sqrt{(f^{-1}x)^2 - 4}}{2} \right)^{2^n} + \left(\frac{f^{-1}x - \sqrt{(f^{-1}x)^2 - 4}}{2} \right)^{2^n} \right\}$$

where

$$fx = -\frac{b}{2c} + \frac{x}{c}$$

$$\xi \phi x = \theta \cos 2\pi \frac{\lambda^2 (f^{-1}x + \sqrt{(f^{-1}x)^2 - 4})}{\lambda 2}$$

(112.) We can thus find either the n th function or the exponential inverse of any of the following forms:

$$\Theta(a+b\Theta^{-1}x)$$

$$\Theta(a(\Theta^{-1}x)^b)$$

$$\Theta\left(\frac{a+b\Theta^{-1}x}{a'+b'\Theta^{-1}x}\right),$$

where Θ is any function whatever. All periodic functions may be directly treated, as in (75.)

(113.) When the exponential inverse is given, the primitive function may be found from the equation

Calculus of
Functions.

Calculus of
Functions.

from which we may also find the expression for $\alpha^n x$, or

$$\alpha x = A^{-1}(Ax - 1),$$

$$\alpha^n x = A^{-1}(Ax - n).$$

(114.) The most general solution of the equation $\phi \psi x = \psi \phi x$ hitherto given is $\psi x = \phi^n x$, where n may be either whole or fractional, positive or negative. Thus $\alpha^m x$ and $\alpha^n x$ are necessarily convertible; and by this method a large class of convertible functions may be found. But in the case where αx is periodic, this method furnishes at first only a finite number of forms convertible with αx .

(115.) The preceding method is directly applicable to the investigation of convertible functions, since

$$\phi \alpha x = \alpha \phi x$$

is solved by eliminating n from the two equations

$$\alpha^n x = \mu \cos 2\pi n \quad \alpha^n y = \nu \cos 2\pi n,$$

in which, however, the present state of analysis will oblige us to assume either μ or ν constant forms.

Assuming $\mu \cos 2\pi n = \text{constant}$, we find

$$n = A(x, c),$$

where the arbitrary constant is explicitly mentioned for convenience. In the same way we find

$$A(y, \cos 2\pi n) = A(x, c),$$

or

$$A(y, \nu \cos 2\pi A x) = A(x, c),$$

whence y is what $A^{-1}Ax$ becomes, when in the second operation A^{-1} a different value of c is used, which is replaced by $\nu \cos 2\pi Ax$ or $\xi \alpha x$ after the completion of the operation. Thus to find those functions which

are convertible with x^p , where $Ax = \frac{\lambda^2 x}{\lambda p} + c$, if we invert this, writing c' for c , we have

$$A^{-1}x = \varepsilon^{p^{-c'-c}},$$

in which, substituting $\frac{\lambda^2 x}{\lambda p} + c$ for x , we get

$$x^{p^{-c'-c}},$$

in which, writing ξx^p for $c - c'$, we have

$$x^{p^{-\xi x^p}}$$

as the most general form which can be obtained of functions which are convertible with x^p . We may reduce this to the more simple form $x^{\xi x^p}$ or $(\xi x^p)^{\lambda^2}$.

(116.) A large number of convertible functions may be deduced as follows. Since $m x$ and $m' x$ are convertible, it follows (49.) that the following pairs are convertible,

$$\begin{array}{ll} \cos m \cos^{-1} x & \text{and} \quad \cos m' \cos^{-1} x \\ \sin m \sin^{-1} x & \text{and} \quad \sin m' \sin^{-1} x \\ \tan m \tan^{-1} x & \text{and} \quad \tan m' \tan^{-1} x, \\ & \&c. \qquad \qquad \&c. \end{array}$$

all of which are common algebraical expressions in a transcendental form. For since, for instance, $\cos m \phi x$ can be expanded where m is a whole number in the form (we take that which is best known)

$$\begin{aligned} & (\cos \phi x)^m - m \cdot \frac{m-1}{2} (\cos \phi x)^{m-2} (1 - \cos^2 \phi x) + \\ & m \cdot \frac{m-1}{2} \cdot \frac{m-2}{3} \cdot \frac{m-3}{4} (\cos \phi x)^{m-4} (1 - \cos^2 \phi x)^2 - \&c. \end{aligned}$$

If for ϕx we write $\cos^{-1} x$, we have the expression

$$\begin{aligned} & x^m - m \cdot \frac{m-1}{2} x^{m-2} (1 - x^2) + \\ & m \cdot \frac{m-1}{2} \cdot \frac{m-2}{3} \cdot \frac{m-3}{4} x^{m-4} (1 - x^2)^2 - \&c., \end{aligned}$$

any two forms of which, for different values of m , are convertible. For instance, let $m = 2$ and $m = 3$ be two values of m ; then we have

$$2x^2 - 1 \text{ and } 4x^3 - 3x,$$

which are convertible functions, that is,

$$4(2x^2 - 1)^3 - 3(2x^2 - 1) = 2(4x^3 - 3x)^2 - 1.$$

(117.) We can also find, by an extension of the preceding method, an indefinite* number of solutions of the following:—What function of $x_1, x_2, x_3, \&c.$ is that which is changed in a given manner by changing x_1 into $\alpha_1 x_1, x_2$ into $\alpha_2 x_2, \&c.$? Find $\alpha_1^n x_1, \alpha_2^n x_2, \&c.$, and let $F_1, F_2, \&c.$ be given functions, and $\mu_1, \mu_2, \&c.$ arbitrary functions. Let y be the function required, and βy the change of form which is to take place. Eliminate $n_1, n_2, \&c.$, and m from as many of the following as may be necessary for the purpose,

$$\begin{aligned} F_1(\alpha_1^n x_1, \alpha_2^n x_2, \dots, \beta^n y) &= \mu_1 \{ \cos 2\pi n_1, \cos 2\pi n_2, \dots \} \\ F_2(\alpha_1^n x_1, \alpha_2^n x_2, \dots, \beta^n y) &= \mu_2 \{ \cos 2\pi n_1, \cos 2\pi n_2, \dots \} \\ &\&c. \qquad \qquad \&c. \end{aligned}$$

The result will be a relation between $y, x_1, x_2, \&c.$, which equally holds between $\beta y, \alpha_1 x_1, \alpha_2 x_2, \&c.$, and y , obtained in terms of $x_1, x_2, \&c.$, will be the function required.

(118.) But cases of the simplest nature will not give a result of any generality of form, considering the wide terms of the question. Suppose, for instance, we ask what is that function of x_1 and x_2 which is not changed by changing x_1 into $x_1 + 1$, when x_2 is changed into $2x_2$. We can eliminate n (in finite terms) from the equations

$$\begin{aligned} 2^{x_1+n} + 2^n x_2 &= \alpha y \\ 2^{x_1+n} &= 2^n x_2 + c, \end{aligned}$$

and we obtain

$$y = c \alpha^{-1} \left(\frac{2^{x_1} + x_2}{2^{x_1} - x_2} \right),$$

which satisfies the conditions: but though it admits of an infinite number of instances, it is not sufficiently general to give the smallest idea of what even, in the present state of analysis, must be considered as the most general solution of the problem.

(119.) And we may give the forms hitherto obtained for ξx an indefinite extension of generality. For if we consider the equation

$$\phi \alpha x = \phi x - 1 \dots (1.)$$

of which Ax is a particular solution, we find

$$\phi \alpha x - A \alpha x = \phi x - Ax,$$

or

$$\phi x - Ax = \text{any form of } \xi \alpha x$$

is also a solution of (1.) Hence for Ax we may write

$$Ax + \xi \alpha x,$$

or

$$\theta \cos 2\pi (Ax + \xi \alpha x)$$

* That is, supposing the n th functions of all the given functions can be expressed.

 Calculus of
Functions.

Calculus of Functions. is also a form of $\xi \alpha x$. Generalizing this process, we find that u_{Ax} is a form of $\xi \alpha x$ if it satisfies the following equation,

$$u_{n+1} = \theta \cos 2\pi (n + u_n),$$

where θ is any function which does not invert the cosine, and where $u_0 = \theta \cos 2\pi A x$.

(120.) The next step in the process of solving functional equations is to find a function which shall not change when either of αx , βx , γx , &c. is substituted for x . We must content ourselves here with showing that we want a process analogous to one of ordinary Algebra, which, if it had not been found, would have left that Science as full of difficulties as is the Calculus of Functions at present.

Let us consider the very simple case of finding a function which shall not be changed either by substitution of $x + 1$ or of x^2 , instead of x . Since then we have

$$\phi(x + 1) = \phi x \quad \phi(x^2) = \phi(x);$$

we have also

$$\phi(x^2 + 1) = \phi x^2 = \phi x$$

$$\phi(x + 1^2 + 1) = \phi x + 1^2 = \phi(x + 1) = \phi x$$

$$\phi(x^2 + 1^2 + 1) = \phi x, \text{ \&c. \&c. \&c.};$$

or generally, if

$$\alpha x = x + 1 \quad \beta x = x^2,$$

$$\phi(\alpha^n \beta^n \alpha^n \beta^n \dots) x = \phi x.$$

If a particular value of ϕ could then be found, say ϕ_1 , in which case $\theta \phi_1$ would be a general value, we should have in one expression a general value of $\xi \alpha x$ for an infinite number of different forms of α , for no one of which can the most limited particular solution be found by our most general previous methods. If this case could then be solved, it would become the most unfailing instrument of removing the difficulties of the preceding; but the converse is not true. For instance, the finding of $\xi(a + bx + cx^2)$ in all cases would be reduced to finding that function which is not changed when

x is changed into $a + bx$ and into $1 + \frac{c}{b}x$.

(121.) In Algebra, the difficulty of resolving such an equation as $\alpha \beta x = \gamma x$ is overcome by developing $\alpha \beta$ and γ in powers of x , that is, changing all functions into functions of one general form. But in the Calculus of Functions there is as yet no theorem by which any function may be expressed in terms of the successive functions of another function, or of functions in any other way related to it.

(122.) The only cases in which the preceding question can now be solved are where the given functions are among the successive functions of some other function. For if $\xi \alpha x = \xi x$, we have $\xi \alpha^2 x = \xi \alpha x = \xi x$, &c., and the same may be extended to algebraical and, under limitation, to functional inverses.

(123.) We shall take this opportunity to lay before the student some idea of the only route by which (if experience be a guide) any of the difficulties of this subject can be removed. The mathematical term *transcendental* is often used, but is seldom specifically defined. The following will be a convenient definition, and will include all the various senses in which the word has been used.

One function is said to be transcendental with respect to another when the second cannot be expressed by any finite number of the operations which are presumed

as granted in the formation of the first. Thus, taking Calculus of Functions. algebraical operations only, if we begin with the addition and subtraction of whole numbers, then multiplications and the raising of powers, in finite numbers, are not transcendental, but divisions, generally speaking, are transcendental, though particular cases may not be so. Thus the 7th part of 1 is a transcendental with respect to addition, subtraction, and multiplication. When we grant a new fundamental operation, we use a new

symbol in all cases; here it is $\frac{1}{7}$. Observe, also, that

this is a transcendental of a peculiar species, which cannot be expressed, even approximately, in terms of additions, subtractions, and multiplications. But if one transcendental of the kind be given, say $\frac{1}{10}$, and the operations of

addition, subtraction, and multiplication be applied to it, we can then express all other transcendentals of the same nature, either directly or approximately. Still

$\left(\frac{1}{10} \text{ and its powers only being granted}\right) \frac{1}{7}$ is a transcendental with respect to whole numbers and $\frac{1}{10}$, the

operations granted being addition, subtraction, multiplication by any whole numbers, and division by 10.

Granting any division, we next come to the operation $\sqrt[n]{a}$, which is generally transcendental,* but not always so. Similarly, the logarithm is a new transcendental, the sine another, if we consider only possible functions, and so on.

(124.) That all transcendentals arise out of inverse operations, springs simply from this, that in selecting operations we are naturally led to choose those combinations of preceding operations which are evidently always possible. But though this may generally be the method, it by no means follows that every subject will admit of it. And it is matter of convenience, sometimes of accident, whether we shall first take that operation which it will ultimately be proper to call direct,† or its inverse. When Napier invented his logarithms, he found $\psi^{-1}x$ where $\psi x = a^x$; when Archimedes found the area of the parabola, he solved a case of integration, which is transcendental with respect to all the curves he considered, instead of differentiation, which, it so happened, was transcendental to none. The ingenuity by which the difficulties of an inverse operation were thus overcome, independently of the direct one, is a principal part of the merit of the two great men alluded to.

(125.) The Calculus of Functions is essentially an inverse calculus, or rather we have presented first the inverse part. We have avoided mentioning the direct calculus in the statement of the conditions under which

* In the following succession, each operation after the third is transcendental with respect to the aggregate of those which precede. Addition, subtraction, multiplication of whole numbers, division, extraction of n th root, formation of logarithm, sine, &c.

† This, however, is true only of particular inverses, absolutely considered. For if the operation $\sqrt[n]{a}$ had preceded a^x it would have been afterwards found convenient to consider the latter as direct, and the former as one of its inverses. According to the received ideas of these terms, the following question is direct: "To what town does this road lead?" and the following inverse: "In how many and what ways can I go to that town?"

Calculus of Functions. it proposes to solve questions. This was done to avoid formally introducing a branch of the subject which is sufficiently considered in ordinary Algebra. But to show the inverse nature of the functional calculus, and thence the high probability of its requiring new transcendentials, we shall now take one or two instances of the direct calculus.

(126.) The general question is, given a number of functions, required the functional relations which exist between any of them and the rest. To take a simple case, suppose we ask what functional relations exist between $x + c$ and $c x^2$. If we call the first αx and the second βx , we ask, what equations of the form

$$F(x, \alpha x, \beta x) = 0$$

must be identically true when $\alpha x = x + c$ and $\beta x = c x^2$. This, it is evident, can be solved in an infinite number of ways; we may, therefore, add some condition or conditions to the general question.

1. Suppose the constant is to be eliminated; we have then

$$\beta x = (\alpha x - x) x^2.$$

2. Suppose x is to be eliminated, except as the subject of a function; then

$$\beta x = c (\alpha x - c)^2.$$

3. Suppose both the former cases are to be included in one. We may do this in an infinite number of ways, for instance,

$$\alpha \beta x = c x^2 + c \quad \beta x = c x^2$$

$$c = \alpha \beta x - \beta x.$$

Let γx be any function of x . The same reasoning gives

$$c = \alpha \beta \gamma x - \beta \gamma x;$$

therefore

$$\alpha \beta \gamma x - \alpha \beta x = \beta \gamma x - \beta x.$$

Or we might differentiate the first value of c with respect to x , which would give

$$\alpha' \beta x = 1 \text{ where } \alpha' x = \frac{d \alpha x}{d x}.$$

4. We may express one function by expressing its n th function in terms of the n th function of the other, and then eliminating n , except where it appears as an index. For instance,

$$\beta^n x = c^{n-1} x^{2^n} \quad \alpha^n x = x + n,$$

whence

$$\alpha^n x - x = \frac{1}{\lambda 2} \{ \lambda^2 c \beta^n x - \lambda^2 c x \}.$$

(127.) Every question of the Calculus of Functions is an inverse to some such question as one of the preceding, and, by experience, we must look for new transcendentials, which is confirmed by our having already found new modifications of the old ones, such as $\cos \lambda x$, &c., or $\frac{1}{2} (x^{\sqrt{-1}} + x^{-\sqrt{-1}})$, and these only in very limited solutions. We have seen that no question, however simple, can be completely solved without the entrance of a transcendental, which is of the following form:

$$f(x, \cos x, \cos \cos x, \cos \cos \cos x, \dots).$$

That is, considering $\cos^n x$ as a separate transcendental for every different value of n , we have an infinite number of transcendentials thus introduced. And even these are only one particular set; for (102.) every different

form of μ in the equation $\alpha^n x = \mu \cos 2 n \pi$ may introduce a different set.

(128.) The difficulties thus introduced by new transcendentials it is useless to attempt to meet by reducing them to the old and well-known forms. The mathematical reader is aware how the attempts to integrate elliptic functions, exponentials of the form $e^{-t^2} dt$, &c., have settled down, so to speak, into the consideration of these quantities as primary functions, in the same manner as λx , $\cos x$, &c., to be calculated and tabulated as the starting points of new branches of analysis. It is most desirable that a similar course should be pursued with respect to other functions.

(129.) The periodic functions have hitherto appeared to stand in some sort of relation to others, similar to that of rational and irrational expressions in Algebra. But we may also find a class of solutions with regard to periodic functions, similar to those which we have attained for others; and we may then show that the new solutions so attained are not really different in form from the results of (87.), obtained by reference to the fundamental property of periodicity. Let ϕx be a periodic function of the second order, then we have

$$\phi^n x = x \cdot \frac{1 + (-1)^n}{2} + \phi x \frac{1 - (-1)^n}{2}.$$

Hence, by equating this to zero, and finding n , we have an exponential inverse of ϕx , namely,

$$\lambda \cdot \left(\frac{\phi x + x}{\phi x - x} \right)^{\frac{1}{\lambda(-1)}},$$

and

$$\xi \phi x = \theta \cdot \cos 2 \pi \lambda \cdot \left(\frac{\phi x + x}{\phi x - x} \right)^{\frac{1}{\pi \sqrt{-1}}},$$

which, by the equation

$$\cos 2 \pi \lambda \psi x = (\psi x)^{2 \pi \sqrt{-1}} + (\psi x)^{-2 \pi \sqrt{-1}},$$

gives

$$\xi \phi x = \theta \left\{ \left(\frac{\phi x + x}{\phi x - x} \right)^2 + \left(\frac{\phi x - x}{\phi x + x} \right)^2 \right\},$$

which, since

$$(\phi x - x)^2 \text{ or } \overline{\phi x + x}^2 - 4 x \phi x,$$

is an unambiguous* function of $\phi x + x$ and $x \phi x$; that is, the preceding is simply equivalent to any function of $\{x + \phi x, x \phi x\}$, or (81.) a symmetrical function of $(x, \phi x)$.

(130.) We may exhibit a form analogous to that already obtained for periodic functions of higher orders, as follows. The function

$$\chi x = x + r \phi x + r^2 \phi^2 x + \dots + r^{n-1} \phi^{n-1} x,$$

where $\phi^n x = x$ and $r^n = 1$, is such that the substitution of ϕx for x is the same thing as multiplication by r^{n-1} , or

$$\chi \phi x = r^{n-1} \chi x,$$

whence an exponential inverse of ϕx is

$$\frac{\lambda \chi x}{(n-1) \lambda r} \text{ or } \frac{\lambda (x + r \phi x + r^2 \phi^2 x + \dots + r^{n-1} \phi^{n-1} x)}{(n-1) \lambda r},$$

or

$$\xi \phi x = \theta \cos 2 \pi \lambda \{ x + r \phi x + \dots + r^{n-1} \phi^{n-1} x \}^{\frac{1}{(n-1) \lambda r}},$$

where $p^{\frac{1}{n-1}}$ means the arithmetical $(n-1)$ th root only.

* θ may be what we please, and therefore is unambiguous. See (81.)

Calculus of Functions. The subject of $\theta \cos 2\pi\lambda$ in the preceding may be reduced as before, in such a way that the whole shall merely imply an arbitrary function of

$$(x + r\phi x + r^2\phi^2 x + \dots + r^{n-1}\phi^{n-1}x)^n,$$

which we might therefore suppose must be a symmetrical function of $x, \phi x, \&c.$ And it is so, because, being of the form $(\chi x)^n$, where an interchange of x and $\phi^m x$ gives

$$\chi \phi^m x = \chi x \times r^{\text{wh. no.}},$$

we have

$$(\chi \phi^m x)^n = \chi x \times r^{\text{mult. of } n} = \chi x.$$

As it is indifferent what root of 1 is taken, we may, when n is an even number, take -1 , which shows that

$$(x - \phi x + \phi^2 x - \dots - \phi^{2n-1}x)^{2n}$$

is a symmetrical function of $x, \phi x, \&c.$

(131.) There is no general method of finding a particular solution of a functional equation, which (101.) is necessary as yet to its complete solution, and (98.) may be suspected to be essential to it. But there is an indefinite number of ways in which the solution of one equation may be made to depend upon that of another, either with or without a particular solution. We shall first take cases in which no particular solution has been found.

(132.) Any function of x may be substituted instead of x throughout the equation. If, for instance, we have

$$\phi \alpha x = \beta x \phi x + \gamma x,$$

where α, β , and γ are known functions, and ϕ is to be found, write κx instead of x , which gives

$$\phi \alpha \kappa x = \beta \kappa x \phi \kappa x + \gamma \kappa x:$$

every solution of this equation is a solution of the original.

1. If $\kappa x = \gamma^{-1}x$, the equation is reduced (writing α for $\alpha\gamma^{-1}$, &c.) to the form

$$\phi \alpha x = \beta x \phi \gamma^{-1}x + x;$$

or, writing ψ for $\phi \gamma^{-1}$, to

$$\psi \gamma \alpha x = \beta x \cdot \psi x + x,$$

which is of the form

$$\psi \alpha x = \beta x \psi x + x.$$

2. If for $\phi \kappa$ we write ψ , we have

$$\psi (\kappa^{-1} \alpha \kappa) x = \beta \kappa x \psi x + \gamma \kappa x.$$

In which, by taking a proper form for κ , we may make either $\beta \kappa x$ or $\gamma \kappa x$ what we please; so that the equation

$$\phi \alpha x = \beta x \phi x + \gamma x$$

can be solved independently of γx , if it can be solved independently of βx , or *vice versa*.

3. Let $\phi x = \mu x \psi x + \nu x$, in which case the equation becomes

$$\mu \alpha x \psi \alpha x + \nu \alpha x = \beta x \mu x \psi x + \beta x \nu x + \gamma x,$$

or

$$\psi \alpha x = \frac{\beta x \mu x}{\mu \alpha x} \psi x + \frac{\beta x \nu x + \gamma x - \nu \alpha x}{\mu \alpha x}.$$

If then νx be a particular solution of the equation itself, and μx a particular solution of

$$\chi \alpha x = \beta x \chi x,$$

the equation is reduced to $\psi \alpha x = \psi x$, or ψx is $\xi \alpha x$; whence, in order to solve

$$\phi \alpha x = \beta x \phi x + \gamma x,$$

we must have particular solutions: 1. of the equation itself; 2. of the equation deprived of its known term; 3. the function which does not change when αx is substituted for x .

(133.) There cannot be two particular solutions of the preceding equation, independent of the form of $\xi \alpha x$. For let $\phi_1 x$ and $\phi_2 x$ be two particular values of ϕ ; then we have

$$\phi_1 \alpha x = \beta x \phi_1 x + \gamma x$$

$$\phi_2 \alpha x = \beta x \phi_2 x + \gamma x$$

$$\phi_1 \alpha x - \phi_2 \alpha x = \beta x (\phi_1 x - \phi_2 x).$$

Consequently, $\phi_1 x - \phi_2 x$ is a particular solution of

$$\chi \alpha x = \beta x \chi x.$$

Let

$$\phi_1 x - \phi_2 x = \chi_1 x,$$

then

$$\frac{\chi \alpha x}{\chi_1 \alpha x} = \frac{\chi x}{\chi_1 x},$$

or $\chi x \div \chi_1 x$ is a particular solution of

$$\xi \alpha x = \xi x;$$

or χx must be of the form

$$(\phi_1 x - \phi_2 x) \xi \alpha x.$$

Take another particular solution, $\phi_3 x$; hence another particular value of χx is $(\phi_3 x - \phi_1 x) \xi_1 \alpha x$, and since

$\frac{\chi_1 x}{\chi_2 x}$ must be a form of $\xi \alpha x$, it follows that

$$\frac{\phi_3 x - \phi_1 x}{\phi_2 x - \phi_1 x}$$

must always be of the form $\xi \alpha x$. Consequently, all the forms $\phi_1, \phi_2, \&c.$ must be included in

$$M \xi \alpha x + N,$$

and obtained by giving different forms to ξ , without changing M and N .

(134.) This remark is important, because it seems to show (as we shall hereafter do more fully) that *some certain* solution of an algebraical character is the *only* such, independent of the transcendentals peculiar to this subject; except only in the case of periodic functions, in which the transcendentals alluded to take algebraical forms. We say *some certain* solutions, because it does not follow that any one we may happen to light upon is the most general of the algebraical forms. This may be tried by following the preceding process, and introducing an arbitrary constant in place of $\xi \alpha x$, which, it is plain, satisfies the conditions. For instance, let

$$\phi(x^2) = \left(x + \frac{1}{x}\right) \phi x - 1,$$

which is evidently satisfied by $\phi_1 x = x$. Consequently, $\phi x - x$ must be a particular solution of

$$\chi(x^2) = \left(x + \frac{1}{x}\right) \chi x,$$

of which $c\left(x - \frac{1}{x}\right)$ is a solution, and every other solution must be of the form $\left(x - \frac{1}{x}\right) \xi(x^2)$. Consequently

$$\phi x = x + \left(x - \frac{1}{x}\right) \xi(x^2),$$

and the most general algebraical form is

Calculus of
Functions.

$$x + c \left(x - \frac{1}{x} \right).$$

(135.) In the same way we can reduce the solution of

$$a_x \phi \alpha x + b_x \phi \beta x + \dots + m_x = 0,$$

where $a_x, b_x, \&c.$ are given functions of x , to the finding a particular solution, and the solution of the equation deprived of its last term. For if ϕ, x be a particular solution, then $\phi x - \phi, x$ is a solution of the equation deprived of its last term: consequently, so many distinct algebraical solutions as we can find of the curtailed equation, so many terms can we give the general value of ϕx . If $p_x, q_x, r_x, \&c.$ be particular algebraical solutions, then

$$\phi x = m_1 p_x + m_2 q_x + \dots$$

where $m_1, m_2, \&c.$ may be constants, which gives the general algebraical form, or forms* of

$$\xi \alpha x \beta x \dots,$$

which gives the most general form.

(136.) In the case where $\alpha, \beta, \&c.$ are successive functions of a periodic function, a particular solution may generally be obtained. Suppose, for instance,

$$\alpha x = \frac{1}{x} \quad \alpha^2 x = x$$

$$\phi \alpha x = (x+1) \phi x + x^2;$$

for x write αx , which gives

$$\phi x = \frac{x+1}{x} \phi \alpha x + \frac{1}{x^2},$$

or

$$\phi x = \frac{(x+1)^2}{x} \phi x + (x+1)x + \frac{1}{x^2}$$

$$\phi x = \frac{x^4 + x^3 + 1}{x^2 - x(x+1)^2}.$$

This is a particular solution only, and we must now look for a particular solution of

$$\phi \alpha x = (x+1) \phi x.$$

This equation admits of no continuous solution, for by substituting αx for x , we find

$$\phi x = \left(\frac{1}{x} + 1 \right) \phi \alpha x,$$

or

$$\left(\frac{1}{x} + 1 \right) (x+1) = 1,$$

which is not true. But from (70.) it may admit of discontinuous solutions.

(137.) To examine this further, let us take

$$\phi \alpha x = \beta x \phi x + \gamma x \quad \alpha^2 x = x$$

$$\phi x = \beta \alpha x \phi \alpha x + \gamma \alpha x$$

$$\phi x = \frac{\gamma \alpha x + \gamma x \beta \alpha x}{1 - \beta x \beta \alpha x}.$$

But

$$\phi \alpha x = \beta x \phi x$$

cannot, as before, be solved, unless

$$\beta x \beta \alpha x = 1,$$

in which case the preceding value of ϕx becomes infinite, unless also

$$\gamma \alpha x + \gamma x \beta \alpha x = 0.$$

* Meaning a function which does not change when $\alpha x, \beta x, \&c.$ are substituted for x .

(138.) First, let

$$\beta \alpha x \beta x = 1,$$

then

$$\phi \alpha x - \beta x \phi x = \gamma x;$$

which, writing αx for x , becomes

$$\phi x - \beta \alpha x \phi \alpha x = \gamma \alpha x;$$

by which, and $\beta \alpha x = \frac{1}{\beta x}$, we find

$$\gamma x + \gamma \alpha x \beta x = 0$$

which is the same as

$$\gamma \alpha x + \gamma x \beta \alpha x = 0.$$

Consequently, the proposed equation can have no continuous solution, unless this second condition be also satisfied. But from the condition $\beta x \beta \alpha x = 1$, the preceding may be thus written,

$$\frac{\gamma \alpha x}{\sqrt{\beta \alpha x}} + \frac{\gamma x}{\sqrt{\beta x}} =$$

of which a solution is

$$\gamma x = \sqrt{\beta x} \theta(x - \alpha x) \times \text{symm. func.}(x, \alpha x),$$

where θx is any function which changes sign when x is changed into $-x$. Substituting this in the original equation, we obtain

$$\phi \alpha x = \beta x \phi x + \sqrt{\beta x} \theta(x - \alpha x) \xi \alpha x,$$

or

$$\sqrt{\beta \alpha x} \phi \alpha x = \sqrt{\beta x} \phi x + \theta(x - \alpha x) \xi \alpha x,$$

which gives

$$\phi x = - \frac{\xi \alpha x \theta(x - \alpha x)}{\sqrt{\beta x}} \frac{\theta_1 x}{\theta_1 x + \theta \alpha x},$$

where $\theta(-x) = -\theta x$ and θ_1 is any function whatever. The form of β must be $\beta x = \theta_2 \alpha x \div \theta_2 x$, where θ_2 is any function whatever. We shall hereafter return to this subject in a more general form. See the Index at the end of this Treatise.

(139.) If we proceed in exactly the same way with

$$\phi \alpha x + \beta x \phi x = \gamma x \quad \alpha^2 x = x,$$

we find the necessary conditions of continuous solution (with an arbitrary function) to be

$$\beta x \beta \alpha x = 1 \quad \gamma \alpha x - \beta \alpha x \gamma x = 0,$$

and the solution is

$$\phi x = \frac{\xi \alpha x}{\sqrt{\beta x}} \frac{\theta_1 x}{\theta_1 x + \theta_1 \alpha x}.$$

In which the student must remember that changing βx into $-\beta x$ changes the form of γx , which will admit of continuous solution, and therefore he is not to attempt to deduce one solution from the other. Take the two equations

$$\left. \begin{aligned} \psi \alpha x + \beta x \psi x &= \gamma x \\ \phi \alpha x - \beta x \phi x &= \gamma x \end{aligned} \right\} \alpha^2 x = x \dots (A)$$

Eliminate γx , determine βx from the result, and then write αx for x ; the equation $\beta x \beta \alpha x = 1$ will then give

$$\frac{\phi \alpha x}{\psi \alpha x} = - \frac{\phi x}{\psi x},$$

which answers to the difference of form already obtained. This is independent of γx , but applying the last condition to the equations, we find

$$\gamma x (\phi \alpha x - \psi \alpha x) = 0,$$

 Calculus of
Functions.

Calculus of Functions. which can only be satisfied by $\gamma x = 0$. So that the two equations (A) cannot both have continuous solutions, unless $\gamma x = 0$.

(140.) The discontinuous solutions of the preceding equation would arise from the application of a general method (if one existed) for the solution of the case where αx is not periodic. We shall now proceed to some simple cases of the latter. Let

$$\phi \alpha x = c \phi x + c',$$

where c and c' are given constants. A particular solu-

tion of this is $\frac{c'}{1-c}$, and a particular solution of $\phi \alpha x =$

$c \phi x$ is $c^{-\Lambda x}$ where Λx is the exponential inverse of αx , which satisfies $\Lambda \alpha x = \Lambda x - 1$; hence a general solution of the given equation is

$$\phi x = \frac{c'}{1-c} + c^{-\Lambda x} \xi \alpha x.$$

Whence the following instances in which the second function given is $c^{-\Lambda x}$, or the multiplier of $\xi \alpha x$ in the general solution of $\phi \alpha x = c \phi x$, that of the original equation being made by addition of $\frac{c'}{1-c}$.

αx	Particular solution of $\phi \alpha x = c \phi x$
$a + bx$	$(a + bx - x)^{\frac{\lambda c}{\lambda b}}$
$a + x$	$c^{\frac{x}{a}}$
bx	$x^{\frac{\lambda c}{\lambda b}}$
ax^b	$\{\lambda (ax^{b-1})\}^{\frac{\lambda c}{\lambda b}}$
x^b	$(\lambda x)^{\frac{\lambda c}{\lambda b}}$
$\frac{a+bx}{a'+b'x}$	$\left(\frac{a+bx-r'x}{a+bx-rx}\right)^{\frac{\lambda c}{\lambda r-\lambda r'}}$ (108.) r and r' unequal
$\frac{a+bx}{a'+b'x}$	$c^{\frac{rx}{a+b x-rx}}$ r and r' equal.

Solutions might also be obtained for all other cases in which αx is a known derivative of one of the preceding.

(141.) Let $\phi \alpha x = \phi x + c'$. The general solution is $\phi x = -c' \Lambda x + \xi \alpha x$.

(142.) Some additional forms may be derived from the preceding by differentiation. It is evident that the solution of $\phi \alpha x = c \phi x$ gives a solution of

$$\alpha' x \psi \alpha x = c \psi x \quad \alpha' x = \frac{d \alpha x}{d x},$$

in which $\psi x = \phi' x$. From this it follows, that if ϕx be a solution of $\phi \alpha x = c \phi x$, $(\phi' x)^m$ is a solution of

$$\psi \alpha x = \left(\frac{c}{\alpha' x}\right)^m \psi x.$$

Hence we find the solution of

$$\phi(x^b) = p x^m \phi x$$

to be

$$\phi x = x^{\frac{m}{b-1}} (\lambda x)^{\frac{\lambda p}{\lambda b}} \xi(x^b);$$

and thus also may be solved the equation

$$\phi\left(\frac{a+bx}{a'+b'x}\right) = (a'+b'x)^m \phi x.$$

(143.) The cases which we cannot succeed in solving generally are very often marked by this peculiarity, that several particular solutions can be obtained, but none containing an arbitrary constant. Thus $\phi^n x = x^p$ has

the solution $\phi x = x^{\frac{1}{p^n}}$, where, r being a primitive n th root of unity, we may write for $p^{\frac{1}{n}}$ either of $\sqrt[n]{p}$, $r \sqrt[n]{p}$, $r^2 \sqrt[n]{p}$... up to $r^{n-1} \sqrt[n]{p}$. The following equation,

$$\phi^n x = \frac{d^n \phi x}{d x^n},$$

admits of a solution of the form $c' x^c$, in which c is a root of the equation

$$c^n - c + m = 0,$$

and

$$c' = \{c \cdot c - 1 \cdot c - 2 \cdot \dots \cdot c - m + 1\}^{\frac{1-c}{m}},$$

which gives $m n$ particular solutions, but contains no arbitrary constant. And, in a similar way, particular solutions may be found to

$$\frac{d^n \phi^b x}{d x^n} = \frac{d^{a'} \phi^{b'} x}{d x^{a'}},$$

all of the form $c' x^c$.

(144.) Many cases occur in which a particular solution may be obtained; but we shall rather proceed to consider such as more immediately depend upon the preceding part of this work. Unless we can combine our various cases by some method of connection, there is little use in considering them at present.

The nature of compound functions is of the first importance. What connection exists between $\phi \psi x$ and $\psi \phi x$? Till something more than we shall be able to exhibit is made known upon this point, the Calculus of Functions will be in much the same position as Arithmetic without the knowledge of the relation which exists between b times a and a times b .

We may call the preceding operations (namely, such as $\phi \psi x$, $\phi \psi \chi x$, &c.) *compound functions* of the second, third, &c. orders, and ϕ , ψ , &c. their *functional factors*. And $\phi \psi$ and $\psi \phi$ may be distinguished by calling the first the *converse* of the second, a term which must be carefully distinguished from the *inverse*. The latter term it might be more logical to call the *contrary*, but custom has settled its present meaning.

(145.) Given the results of a compound operation of the second order, and of its converse, required the operations themselves. That is, to solve the equations

$$\phi \psi x = \alpha x \quad \psi \phi x = \beta x,$$

which give

$$\alpha x = \phi \beta \phi^{-1} x \quad \text{and} \quad \beta x = \psi \alpha \psi^{-1} x;$$

and therefore ϕ and ψ are respectively the functions by which α is a derivative of β , and β of α . From the method of determining these functions, given in (50.), it appears that ϕ and ψ are in form inverse to each other. But as they cannot be real inverses of each other, since then $\phi \psi x$ and $\psi \phi x$ would be respectively $= x$, the forms only must be preserved, and different arbitrary constants or functions taken. But this will require that one relation should exist between those two arbitrary constants or functions. For instance, let us propose

$$\phi \psi x = \cos a \cos^{-1} x \quad \psi \phi x = \cos b \cos^{-1} x;$$

the method requires that we should eliminate n between $\cos a^n \cos^{-1} x = c$ and $\cos b^n \cos^{-1} y = c'$,

Calculus of which gives
Functions.

$$\begin{aligned} y &= \cos \left\{ C (\cos^{-1} x)^{\frac{\lambda b}{\lambda a}} \right\} \\ \psi x &= \cos \left\{ C (\cos^{-1} x)^{\frac{\lambda b}{\lambda a}} \right\} \quad \phi x = \cos \left(C' (\cos^{-1} x)^{\frac{\lambda a}{\lambda b}} \right) \\ \psi \phi x &= \cos (C C'^{\frac{\lambda b}{\lambda a}} \cos^{-1} x) \\ \phi \psi x &= \cos (C' C^{\frac{\lambda a}{\lambda b}} \cos^{-1} x) \end{aligned}$$

which satisfy the original conditions, if

$$C C'^{\frac{\lambda b}{\lambda a}} = b, \text{ which gives } C' C^{\frac{\lambda a}{\lambda b}} = a.$$

(146.) But if α and β be corresponding derivatives of two other functions, as in the preceding case, the question may be reduced as follows. Let it be required to solve

$$\phi \psi x = \Theta \alpha \Theta^{-1} x \quad \psi \phi x = \Theta \beta \Theta^{-1} x,$$

and let $\phi_1 x$ and $\psi_1 x$ be solutions of

$$\phi_1 \psi_1 x = \alpha x \quad \psi_1 \phi_1 x = \beta x;$$

then assume

$$\phi x = \Theta \phi_1 \Theta^{-1} x \quad \psi x = \Theta \psi_1 \Theta^{-1} x.$$

(147.) If we apply the preceding conditions to the solution of

$$\phi \psi x = a x \quad \psi \phi x = x^b,$$

we find

$$\phi x = a c^{-\frac{\lambda a}{\lambda b}} (\lambda x)^{\frac{\lambda a}{\lambda b}} \quad \psi x = e^{c x^{\frac{\lambda b}{\lambda a}}},$$

consequently to solve

$$\phi \psi x = a(x+m) - m \quad \psi \phi x = (x+m)^b - m,$$

we have

$$\phi x = a c^{-\frac{\lambda a}{\lambda b}} (\lambda x + m)^{\frac{\lambda a}{\lambda b}} - m \quad \psi x = e^{c(x+m)^{\frac{\lambda b}{\lambda a}}} - m.$$

(148.) The following question is a particular case of the last, in the same manner as that in (102.) is a particular case of that in (50.) Required a function, of which one of the inconvertible inverses shall be such that $\phi_{-1} \phi x$ is a given function of x . For instance, suppose

$$\phi \psi x = x \quad \psi \phi x = x^b,$$

in which, by the first equation, ψ is an inverse of ϕ ; and, by the second equation, not a convertible inverse. If we eliminate n between the equations

$$y = \cos 2\pi n \quad x^n = c,$$

and pursue the preceding method, we find

$$\phi x = \cos 2\pi \left(\frac{\lambda^2 c' - \lambda^2 x}{\lambda b} \right)$$

$$\psi x = c^{\frac{1}{2\pi} \cos^{-1} x},$$

and the condition $c = c^b$ makes

$$\phi \psi x = x \text{ and } \psi \phi x = x^{\frac{\lambda c}{\lambda c'}},$$

which is a very limited particular case of the problem in question.

(149.) By the same method convertible functions may be found, but not in a more general form than that already given in (115.)

(150.) Required a function which shall be inverted with respect to one variable, by an interchange of two others. Of this a particular case is $x + y = z$, the inverse of which with respect to x is $x + z = y$.

Take any two similar functions of z and y , but which

have the same form with respect to x . Calling $\alpha_x x$ and $\alpha_y x$ these* functions, solve

$$\phi \psi x = \alpha_x x \quad \phi \psi x = \alpha_y x;$$

then while by the method of solution ψx is (the constant excepted) an inverse of ϕx , it is evident that, in the equations themselves, an interchange of z and y , accompanied by an interchange of ϕ and ψ , makes no change in the conditions of the problem. But the relation between the constants must be determined according to the particular forms of each case.

For instance, if we assume

$$\alpha_x x = \cos z \cos^{-1} x \quad \alpha_y x = \cos y \cos^{-1} x,$$

we find the function in question to be

$$\cos \left\{ (\cos^{-1} x)^{\frac{\lambda y}{\lambda z}} \right\},$$

and it may easily be shown that the derivatives of functions which possess this property also have the same; so that

$$\phi(\phi^{-1} x + y - z) \quad \phi\left(\frac{y}{z} \phi^{-1} x\right) \quad \phi\left((\phi^{-1} x)^{\frac{y}{z}}\right)$$

are all functions in which y and z are interchanged by inversion with respect to x .

(151.) Converse functions are simple derivatives of each other. Thus $\alpha \beta$ is $\alpha \beta \alpha^{-1}$ or $\alpha(\beta \alpha) \alpha^{-1}$. Hence converse functions are periodical together, and the n th function of either is directly ascertained from that of the other. And since any inconvertible inverse α_{-1} gives $\alpha \alpha_{-1} x = x$, we have $\alpha \alpha_{-1} \alpha \alpha^{-1} x = x$, or $\alpha_{-1} \alpha x$ being βx , we find that αx is a value of $\xi \beta x$. This is evident in the case chosen in (148.)

(152.) We now turn our attention to the general equation

$$\phi^n x = \alpha x \dots (1),$$

the solution of which is the general expression for

$\alpha^n x$, or the n th functional inverse of x . It would appear at first sight that $\phi^n x = x$ ought to be considered as a particular case of this, and undoubtedly it will be so considered when the solutions of functional equations are as general as the ideas implied in the equations themselves. But in the mean while the following argument will show that a peculiarity of x as distinguished from αx makes every solution which we can obtain of (1) appear much less extensive than those of $\phi^n x = x$.

From the preceding equation it follows that

$$\phi^n(\phi x) \text{ being } = \phi(\phi^n x) \quad \therefore \phi \alpha x = \alpha \phi x,$$

or ϕ and α must be convertible. Now when $\alpha x = x$, it is convertible with every function of x ; but when αx is any other function of x , however simple, it is convertible only with a very inconsiderable variety of forms, and those not all assignable at present. Now though $\phi^n x = x$ is a case of $\phi^n x = \alpha x$, we cannot for any useful purpose consider them together, until we have some idea how to fill up the void, if we may so speak, between αx and x , so as to assign functions continually approaching nearer and nearer to x in the extensiveness of the forms with which they are convertible. See (9.) and (27.)

(153.) One solution of $\phi^n x = \alpha x$ arises from the substitution of $\frac{1}{n}$ instead of n in the expression for $\alpha^n x$. But

* We here adopt a combination of the notation α_x and αx mentioned in (14.), to signify that while $\alpha_x x$ and $\alpha_y x$ are cognate functions of x , they are similar functions of z and y . Here x is the subject to which the stated property is referred.

Calculus of
Functions.in like manner as we found various forms of $\phi^{-1}x$ in (33.),by writing $\phi x = \alpha x$ in the form $\phi x = \alpha x \cdot e^{2k\pi\sqrt{-1}}$, k being any positive or negative whole number, so we may find many forms (whether all or not we cannot say)of $\frac{1}{\alpha^n}x$, by substituting for αx the form $\alpha x \times e^{2k\pi\sqrt{-1}}$. For instance, let us suppose $\alpha x = x^a$, obvious n th functional inverses of which are the n forms of $x^{\frac{1}{a^n}}$. But suppose

$$\phi^n x = x^a e^{2k\pi\sqrt{-1}}.$$

Then, remembering that if

$$\beta x = p x^q, \quad \beta^n x = p^{\frac{n}{q-1}} x^{q^n},$$

we find

$$\phi x = e^{\frac{1}{a^n-1} 2k\pi\sqrt{-1}} x^{\frac{1}{a^n}}$$

$$= \left\{ \cos\left(\frac{1}{a^n-1} 2k\pi\right) + \sqrt{-1} \sin\left(\frac{1}{a^n-1} 2k\pi\right) \right\} x^{\frac{1}{a^n}},$$

which gives an infinite number of values, corresponding to the positive and negative whole values of k , in n different series corresponding to the n forms of $\frac{1}{a^n}$; one of these series containing only a finite number when $\frac{1}{a^n}$ and a are commensurable with the unit. The convertibility of the preceding expression with x^a is easily established, if we remember that

$$\frac{a^{\frac{1}{a^n}-1}}{a-1} \times a = \frac{a^{\frac{1}{a^n}+1}-1}{a-1} - 1;$$

and thus we have an extension of the forms of the functions which are convertible with x^a .

We shall here take the opportunity of observing that, if n be increased without limit, the limit of the preceding is x , or $\phi^n x$, as we might suppose it would be.

(154.) A similar extension of form may be given to the values of $\phi^n x$ deduced in (46.), though without prejudice to the truth of the remarks in (48.). If in the first example we assume $v_{n+1} = 2v_n + k\pi$, k being any positive or negative whole number, we have, if

$$\phi x = \tan 2 \tan^{-1} x = \frac{2x}{1-x^2}$$

$$\phi^n x = \tan \{2^n \tan^{-1} x + (2^n - 1)k\pi\};$$

which is equally true when n is fractional, but which in the latter case gives as many different values as there may be values of k .

(155.) But we have not any reason to suppose that we can thus, even in these simple cases, give the most remote idea of the general nature of the function which, repeated n times, will give αx . Nor can we, from analogy, suppose the complete solution of any inverse operation which does not contain an arbitrary function or functions. And if we are to treat forms as different, which we cannot prove to be the same, the following consideration will show that we are not even to suppose

that $\alpha^n x$ is limited in the number or character of its arbitrary functions, but may require an infinite number of arbitrary functions, with different subjects.

Let us again take $\phi^n x = \alpha x$; and suppose α to be a derivative of βx ; thus

$$\alpha x = \mu \beta \mu^{-1} x.$$

Calculus of
Functions.

In the general determination of μ from β , an arbitrary function must be supposed to appear, from (50.) If we now assume $\phi x = \mu \psi \mu^{-1} x$, we find that the original equation is satisfied by $\psi^n x = \beta x$, in the general solution of which an arbitrary function also enters. Consequently, in determining $\mu \psi \mu^{-1} x$, we produce a result with two arbitrary functions, having no means of proving that these two reduce themselves to one, and knowing that very different forms can be given to the two functions, because the first depends upon β and α , and the second on β only; while β may be any given form. And being thus able to vary the forms of the arbitrary function, the general solution must be one which, explicitly or implicitly, contains every possible form. We may, therefore, conceive it possible that the general solution contains an infinite number of arbitrary functions, the subjects of which must satisfy one or more relations derived from the nature of the function αx .

On the other hand, perhaps the preceding reasoning may lead some to suspect that there should be no arbitrary function in the solution of $\phi^n x = \alpha x$. And the following reasoning may appear to be in favour of such a suspicion. If we could find $\varpi(x, c)$ a particular solution of $\psi^n x = \beta x$, containing an arbitrary constant, the latter might be immediately converted into an arbitrary function by substituting θx , the solution of

$$\theta \varpi(x, \theta x) = \theta x \dots (A).$$

Now, as yet we have not the means of introducing even an arbitrary constant (other than an integer) into any single case of $\alpha^n x$.

(156.) The following method of solving $\psi^n x = \alpha x$ is given by Mr. Babbage.* Assume

$$\psi x = \phi f \phi^{-1} x \quad \alpha x = \phi f^n \phi^{-1} x,$$

where f is a known function. The solution of the question is then reduced to the determination of ϕ from

$$\phi f^n x = \alpha \phi x.$$

Let us proceed to solve this as in (50.) If we call F and A the exponential inverses of f and α , and eliminate m from the two equations

$$f^m x = c \quad \alpha^m \phi x = c',$$

we find

$$m n = F x \quad m = A \phi x$$

$$\phi x = A^{-1} \frac{1}{n} F x \quad \phi^{-1} x = F^{-1} n A x$$

$$\psi x = A^{-1} \frac{1}{n} F f F^{-1} n A x = A^{-1} \left(A x - \frac{1}{n} \right),$$

because

$$F f x = F x - 1 \quad F f F^{-1} x = x - 1,$$

a form in which the n th functional inverse has already been obtained. With the forms of exponential inverses, which are actually attainable, the preceding method is therefore equivalent to the actual expression of $\alpha^n x$, by giving n a fractional value. But for any thing which appears to the contrary, the solution of

$$f^m x = \mu \cos 2\pi m \quad \alpha^m \phi x = \nu \cos 2\pi m$$

may contain more general solutions. But some attempts which we have made lead to an ambiguity which will occur in a less complicated form hereafter.

(157.) The whole question relative to the solution of $\psi^n x = \alpha x$ is thus reduced to the solution of $\psi^n x = x - 1$;

* Essay, &c. Phil. Trans., 1815.

Calculus of Functions. since any particular solution of this, ϖx for example,

gives $A^{-1} \varpi A x$ for a value of $\alpha^{\frac{1}{n}} x$, where A is the exponential inverse of α . But we have not any direct means of determining any other values for ψx , except $x - \frac{1}{n}$. But by referring all functions to x^a , we may

arrive at a value of $\alpha^{\frac{1}{n}} x$ for every value there given of the n th functional inverse of x^a ; as follows:

Since we have generally (50.)

$$\alpha x = A^{-1} B \beta B^{-1} A x,$$

(where α and β are any functions whatsoever, and A and B their exponential inverses) let $\beta x = x^a$, in which case

$$B x = -\frac{\lambda^2 x}{\lambda a} \quad B^{-1} x = e^{x \lambda a}.$$

Let ϖx be a value of $\beta^{\frac{1}{n}} x$: whence we find by successive operation, that

$$A^{-1} B \varpi B^{-1} A x$$

is a value of $\alpha^{\frac{1}{n}} x$. Take for ϖx its value already obtained in (153.), namely,

$$\lambda^{-1} \left(\frac{a^{\frac{1}{n}} - 1}{a - 1} 2 k \pi \sqrt{-1} \right) \times x^{\frac{1}{a}},$$

using $\lambda^{-1} x$ for e^x . We have then

$$\varpi B^{-1} A x = \lambda^{-1} \left(\frac{a^{\frac{1}{n}} - 1}{a - 1} 2 k \pi \sqrt{-1} \right) \times (\lambda^{-2} - \lambda a A x)^{\frac{1}{a}}.$$

and therefore $\alpha^{\frac{1}{n}} x$ or $A^{-1} B \varpi B^{-1} A x$ is the function A^{-1} of

$$-\frac{1}{\lambda a} \lambda^2 \left\{ \lambda^{-1} \left(\frac{a^{\frac{1}{n}} - 1}{a - 1} 2 k \pi \sqrt{-1} \right) \times (\lambda^{-2} - \lambda a A x)^{\frac{1}{a}} \right\}.$$

But here we must observe, that the absolute manner in which the n th inverse of x^a was obtained depended upon the successive operations not inverting $e^{2k\pi\sqrt{-1}}$, so that the result appeared in the form $e^{2k\pi\sqrt{-1}} \cdot x^a$, or x^a . But in any other case we must remember that the use of the general form $\phi x \times e^{2k\pi\sqrt{-1}}$ requires an equally general form of inversion: and without it, as we shall see, we cannot make the preceding give an n th inverse of αx , but only of a particular class of its derivatives. If then we assume

$$\lambda \lambda^{-1} \left(\frac{a^{\frac{1}{n}} - 1}{a - 1} 2 k \pi \sqrt{-1} \right) = \frac{a^{\frac{1}{n}} - 1}{a - 1} 2 k \pi \sqrt{-1} + 2 k' \pi \sqrt{-1}$$

$$\lambda \lambda^{-2} (-\lambda a A x) = \lambda^{-1} (-\lambda a A x) + 2 k'' \pi \sqrt{-1},$$

and substitute, writing

$$K \text{ for } \frac{a^{\frac{1}{n}} - 1}{a - 1} k + k' + a^{\frac{1}{n}} k'',$$

we have for the value of $\alpha^{\frac{1}{n}} x$

$$A^{-1} \left\{ -\frac{\lambda (2 \pi K \sqrt{-1} + a^{\frac{1}{n}} \Theta^{-1} x)}{\lambda a} \right\}.$$

(158.) We may easily discover the conditions of verification of this expression by observing that it is a derivative of

$$2 \pi K \sqrt{-1} + a^{\frac{1}{n}} x,$$

or that it is

$$\Theta (2 \pi K \sqrt{-1} + a^{\frac{1}{n}} \Theta^{-1} x)$$

where

$$\Theta x = A^{-1} \left(-\frac{\lambda x}{\lambda a} \right) \quad \Theta^{-1} x = a^{\frac{1}{n}} x,$$

whence, the n th function of

$$2 \pi K \sqrt{-1} + a^{\frac{1}{n}} x \text{ being } \frac{a - 1}{a^{\frac{1}{n}} - 1} 2 \pi K \sqrt{-1} + a x,$$

the n th function of the preceding is

$$\Theta \left(\frac{a - 1}{a^{\frac{1}{n}} - 1} 2 \pi K \sqrt{-1} + a \Theta^{-1} x \right),$$

the only apparent case in which this gives the value αx or $A^{-1} (A x - 1)$ is when $K = 0$, which explicitly reduces the n th function to the form $A^{-1} (A x - 1)$; so that, returning to the general form, we find the follow-

ing as an expression for $\alpha^{\frac{1}{n}} x$; namely,

$$A^{-1} \left[-\frac{1}{\lambda a} \lambda^2 \left\{ \lambda^{-1} \left(\frac{a^{\frac{1}{n}} - 1}{a - 1} 2 \pi k \sqrt{-1} \right) \times (\lambda^{-2} a^{-\lambda x})^{\frac{1}{a}} \right\} \right]$$

subject to the following equation between the arbitrary integers implied in its most general meaning;

$$\frac{a^{\frac{1}{n}} - 1}{a - 1} k + k' + a^{\frac{1}{n}} k'' = 0.$$

Various functions will arise in which the equation of condition becomes unnecessary; but, generally speaking, it must not be neglected.

Unsatisfactory as the preceding must necessarily be, we have thought it might be useful, in order to direct the attention of our readers to this curious and by no means finally settled subject of the inversion of the exponential function of Algebra.* The difficulty is of the same character as that contained in $\cos^{-1} \cos x$, or any other function which has different inverses, and is comparatively little felt in problems whose scope and meaning have been more attended to than the present one. We see, however, that we have not yet succeeded in obtaining a solution with an arbitrary constant: for though a is such at the outset, the equation of condition deprives it of that character, by making it a function of arbitrary integers only.

The solution of $\psi^n x = \alpha x$, in all its generality, is a fundamental inquiry in the subject of the present Treatise: nor can more essential progress be looked for without it, than in common Algebra without the complete solution of $x^n = 1$. Our own suspicion is, that the solutions are infinite in number, but embraced under a finite number of forms; but we hope the subject will be further considered.

(159.) The method of representing the n th functions

* The extension lately asserted of the logarithms of unity and of numbers in general has not been adopted by us, because we cannot agree with those who think it established. The fundamental assumptions have not been explained with sufficient clearness for us to undertake to specify our objections. If it be really meant to be asserted that

e to the $(2k \div 2k' - \sqrt{-1})$ th power = 1,

in the usual sense of such a formula, we must entirely dissent from the conclusion.

Calculus of Functions.

Calculus of Functions. of a periodic function in (66.) fails, as we have seen, to give a form of their functional inverses. And it is necessary that every such inverse of a periodic function should be a periodic function: for if $\phi^n x = \alpha x$, where $\alpha^n x = x$, we must have $\phi^n x = x$. And since these conditions

can be fulfilled in periodic functions of the form $(1)^{\frac{1}{n}}x$, $x^{(1)^{\frac{1}{n}}}$, &c., and since any periodic function may be made a derivative of any other of the same kind, we can express any periodic function of the p th order in the form $\phi(1)^{\frac{1}{p}}\phi^{-1}x$, and the n th functional inverse of this will be $\phi(1)^{\frac{1}{np}}\phi^{-1}x$. The arbitrary function contained in the general method of determining ϕ , given in (75.), shows that in this case, at least, there is an arbitrary function in $\alpha^n x$, unless, which may happen, it disappears in forming $\phi(1)^{\frac{1}{np}}\phi^{-1}x$ as well as $\phi(1)^{\frac{1}{n}}\phi^{-1}x$.

(160.) We now take the equation $\phi^n x = \alpha^n x$, of which one class of solutions is contained in the various n th inverses of $\alpha^n x$. But another class is found as follows. Let β be any periodic function of the order n , or a submultiple of n , and assume $\phi x = \beta \alpha x$. Then, if β and α be convertible, it is easily shown that $\phi^n x$ is the same as $\beta^n \alpha^n x$ or $\alpha^n x$. Thus $\frac{1}{x}$ being a periodic function of

the second order, convertible with x^2 , $\frac{1}{x^2}$ is a solution of $\phi^2 x = x^4$. But we are not in possession of any method by which it can be found what periodic functions are convertible with any given function.

(161.) If it ever be necessary to consider the successive functions of αx as derivatives of each other, it may be done by the method of (50.), and the result will be as follows: if

$$\alpha^p x = f \alpha^q f^{-1} x,$$

then $f x$ must be deduced from the equation

$$\frac{A f x}{A x} = \frac{p}{q},$$

where $A x$ is the exponential inverse of αx , and different values of the arbitrary constant may be employed in the numerator and denominator.

The following theorem may also be deduced. Let

$$\alpha^p x = f_p \alpha f_p^{-1} x,$$

and let

$$\alpha^{p+1} x = \phi_p \alpha^p \phi_p^{-1} x,$$

then among all the functions which may be found to satisfy the conditions imposed on f_p and ϕ_p , a set may be found between which the following relations exist:

$$\begin{aligned} f_2 x &= \phi_1 x \\ f_3 x &= \phi_2 \phi_1 x \\ f_4 x &= \phi_3 \phi_2 \phi_1 x, \text{ \&c.,} \end{aligned}$$

or

$$f_{n+1} x = \phi_n \phi_{n-1} \dots \phi_{n-p} f_{n-p} x.$$

(162.) Mr. Babbage* has given the following method of ascertaining the value of a function which does not change when x is changed into $\alpha_1 x, \alpha_2 x, \dots, \alpha_n x$. Find a particular solution of $\xi \alpha_1 x$, which call $f_1 x$; then find a particular solution of $\xi \alpha_2 x$, and find what function the latter is of $f_1 x$, or exhibit it in the form $f_2 f_1 x$: so that

Calculus of Functions. $f_2 f_1 \alpha_2 x = f_2 f_1 x$: similarly, let $f_3 f_2 f_1 x$ be a particular solution of $\xi \alpha_3 x$, and so on. Then will $\theta(f_n f_{n-1} \dots f_2 f_1 x)$ be a general solution of the requisite conditions: for though, for instance, $f_1 \alpha_2 x$ is different from $f_1 x$, yet similarity of form is restored by the operation f_2 , and so on for the rest. A similar method may be applied to the solution of the simultaneous equations $\phi \alpha_1 x = \phi \beta_1 x$, $\phi \alpha_2 x = \phi \beta_2 x$, which indeed amounts to substituting in the preceding $\alpha_1 \beta_1^{-1} x$ for $\alpha_1 x$, and so on.

(163.) But the preceding process must be subject to the condition that f_n does not invert f_{n-1} , f_{n-1} does not invert f_{n-2} , &c. according to the remark in (99.) We shall proceed to some instances.

Let $m x$ and $n x$ be the functions in question. A particular solution of $\phi(m x) = \phi x$ is $\cos 2\pi \frac{\lambda x}{\lambda m}$: we have therefore to solve the equation

$$\phi \cos 2\pi \frac{\lambda n x}{\lambda m} = \phi \cos 2\pi \frac{\lambda x}{\lambda m}.$$

Let

$$\cos 2\pi \frac{\lambda x}{\lambda m} = \Theta x \quad \phi \Theta n x = \phi \Theta x,$$

or

$$\phi \Theta n \Theta^{-1} x = \phi x,$$

where $\phi \Theta x$ is the function now to be found, and ϕx is itself, by preceding methods, the same as $\psi \Theta^{-1} x$ where $\psi n x = \psi x$. Hence $\psi \Theta^{-1} \Theta x$ is the function in question, which is, for convertible inverses, the same as $\psi n x$, which by hypothesis (unless the solution is assumed in the solution) satisfies $\psi n x = \psi x$ only. We have then, owing to the inversion above alluded to, and contrary to the limitation mentioned in (99.) abandoned the condition already satisfied, in trying to secure the other. And it must be observed that the theorem of (104.) is not true, if an inconvertible inverse of Θ be made to take the place of Θ^{-1} .

(164.) If, however, taking inconvertible inverses, we carry on the process, we may arrive at this sort of solution, namely, an ambiguous function of x , which shall be absolutely unchanged when x is changed into $n x$, and changed from one of its values to another when x is changed into $m x$. For we find $\psi x = \cos 2\pi \frac{\lambda x}{\lambda n}$.

$$\Theta_{-1} x = \varepsilon^{\frac{\lambda m}{2\pi} \cos^{-1} x}$$

$$\begin{aligned} \psi \Theta_{-1} \Theta x &= \cos 2\pi \frac{1}{\lambda n} \lambda \varepsilon^{\frac{\lambda m}{2\pi} \cos^{-1} \cos 2\pi \frac{\lambda x}{\lambda m}} \\ &= \cos \frac{\lambda m}{\lambda n} \left(2\pi \frac{\lambda x}{\lambda m} + 2w\pi \right). \end{aligned}$$

where w is any whole number, positive or negative. This is

$$\cos 2\pi \left(\frac{\lambda x}{\lambda n} + w \frac{\lambda m}{\lambda n} \right),$$

in which a change of x into $n x$ causes no change, and x into $m x$ adds 1 to w , or gives another value of the function. The conditions are indeed satisfied when m is a whole power of n , but this gives only a case of $\phi \alpha^p x = \phi x$, following from $\phi \alpha x = \phi x$.

If possible, let there be a function of x which does not change when x is changed into $m x$ or $n x$. It is easily proved that it will not change when $m^a n^b x$ is substituted for x , a and b being any two whole numbers, positive or negative. But these whole numbers may be

* Philosophical Transactions, 1815.

Calculus of
Functions.

so taken, that m^n may, if λm and λn be incommensurable, be made as near as we please to any given quantity c . Hence the *continuous* solution, in a form independent of the specific values of m and n , is a solution of $\phi cx = \phi x$, for all values of c . Such a solution is then impossible, in any sense in which we consider equations as solved in Algebra.

(165.) The preceding solution is an accident arising from our having functions for which $\Theta_{-1} \Theta x$ is of the form $x + c$. If we take x^m and $n x$, and extend the theorem in (104.) to the case where Θ_{-1} is written for Θ^{-1} , for trial only, according as we take one function or the other first, we arrive at the results

$$\cos 2\pi \frac{m^n \lambda x}{\lambda n} \text{ and } \cos 2\pi \frac{\lambda (\lambda x + w \lambda n)}{\lambda m};$$

the first of which again, by a peculiarity of this case, is such a solution as that in the last article for all *whole* values of m , and *positive whole* values of w . The second is not in any case such a solution, but it leads us to the following remark.

If we may suppose w to have any value whatsoever, then the second formula becomes a solution of the question; for the substitution of x^m instead of x gives

$$\cos 2\pi \frac{\lambda \left(\lambda x + w \frac{\lambda n}{\lambda m} \right) + \lambda m}{\lambda m},$$

equivalent to changing w into $\frac{w}{\lambda m}$: while the substitution of $n x$ for x gives

$$\cos 2\pi \frac{\lambda (\lambda x + (w + 1) \lambda n)}{\lambda n},$$

which is equivalent to changing w into $w + 1$. We can, by this method, generally obtain a solution of the following problem: Given $\alpha_1 x, \alpha_2 x, \&c.$, required such a function ϕx , that $\phi \alpha_1 x, \phi \alpha_2 x, \&c.$ shall only differ from ϕx in the values of constants.

(166.) Let us take any two functions, αx and βx , the exponential inverses of which are $A x$ and $B x$, and $\cos 2\pi A x$ is a value of $\xi \alpha x$. We have, therefore, to solve the equation

$$\phi \cos 2\pi A \beta x = \phi \cos 2\pi A x;$$

so that $\phi \cos 2\pi A x$ may be a value both of $\xi \alpha x$ and $\xi \beta x$. A value of ϕx (102.) is $\cos 2\pi B A^{-1} \frac{1}{2\pi} \cos^{-1} x$,

and therefore the equation derived from the preceding method is

$$\phi \cos 2\pi A x = \cos 2\pi B A^{-1} (A x + w) \text{ or } \cos 2\pi B \alpha^n x$$

as appears from (105.), since w may be indifferently a positive or negative whole number. Here it is evident that in all cases the substitution of αx for x is the alteration of a constant, and that if αx and βx be convertible, the substitution of βx for x changes $B \alpha^n x$ into $B \beta \alpha^n x$ or $B \alpha^n x - 1$ giving no change in the cosine.

Thus the ambiguous solution of the first example may be obtained in all cases of convertible functions.

(167.) If the two functions in question be periodic and convertible, the condition may be generally satisfied. If, for instance, αx and βx be periodic convertible functions of the second order, then

$$x + \alpha x + \beta x + \alpha \beta x$$

does not change when x is changed into αx , or into βx , becoming in these two cases

$$\alpha x + x + \beta \alpha x + \beta x$$

and

$$\beta x + \alpha \beta x + x + \alpha x,$$

which are equal, since $\alpha \beta x = \beta \alpha x$. Hence

$$\theta (x + \alpha x + \beta x + \alpha \beta x) = \phi x$$

fulfils the conditions $\phi \alpha x = \phi x, \phi \beta x = \phi x$.

Similarly, periodic and convertible functions of the third order, αx and βx , being given, the function

$$\theta \left(\begin{array}{l} x + \alpha x + \beta x \\ + \alpha^2 x + \alpha \beta x + \beta^2 x \\ + \alpha^2 \beta x + \alpha \beta^2 x + \alpha^2 \beta^2 x \end{array} \right)$$

satisfies the conditions $\phi \alpha x = \phi \beta x = \phi x$.

And generally, if $\alpha_1 x, \alpha_2 x, \dots, \alpha_m x$ be m periodic functions of the n th order, which are mutually convertible, two and two, it follows that

$$\theta (\Sigma \alpha_1^{a_1} \alpha_2^{a_2} \alpha_3^{a_3} \dots \alpha_m^{a_m} x),$$

for every value of each of the quantities $a_1, a_2, \dots$, between 0 and $n - 1$ inclusive, satisfies the conditions

$$\phi \alpha_1 x = \phi x \quad \phi \alpha_2 x = \phi x, \&c.$$

(168.) When periodic functions are not convertible, a similar formula may be constructed, if their compound functions are periodic: but it must be observed, that in the case of periodic functions of the second order, if the compound function be periodic, and of the second order, the functions must be convertible: and the converse. For if

$$\alpha^2 x = x \quad \beta^2 x = x \quad \alpha \beta \alpha \beta x = x,$$

we have

$$\alpha^2 \beta \alpha \beta x = \alpha x \text{ or } \beta \alpha \beta x = \alpha x \\ \beta \alpha \beta^2 x = \alpha \beta x \text{ or } \beta \alpha x = \alpha \beta x.$$

(169.) When the compound function is not periodic we have no method of solving this question. In fact, if $\phi \alpha x = \phi x, \phi \beta x = \phi x, \alpha^n x = x, \beta^n x = x$, we have also $\phi \alpha \beta x = \phi x$, and if $\alpha \beta$ be not periodic, we cannot solve this equation directly or indirectly, except only in the case where $\alpha \beta$ is one of the forms noticed in (112.)

(170.) We shall now give some methods of reduction of functional equations to more simple forms. Several are derived from Mr. Babbage's Papers in the *Philosophical Transactions*. Indeed, without these papers, and the elementary treatise of examples published with the examples to the Cambridge translation of Lacroix, the third branch of the subject mentioned in (94.) could not have been said to exist in a defined form.

Let

$$(\psi \alpha)^n \psi \beta x = \gamma x,$$

where by $(\psi \alpha)^2$ is meant $\psi \alpha \psi \alpha, \&c.$, and the reader must not confound $(\psi \alpha)^n$ with $\psi^n \alpha^n$, the two being the same only when ψ and α are convertible. Let

$$\psi \alpha x = \phi f \phi^{-1} x,$$

which gives

$$\phi f^n \phi^{-1} \phi f \phi^{-1} \alpha^{-1} \beta x = \gamma x,$$

or

$$\phi f^{n+1} \phi^{-1} \alpha^{-1} \beta x = \gamma x,$$

or

$$\phi f^{n+1} x = \gamma \beta^{-1} \alpha \phi x:$$

this equation may also be reduced to

$$\chi^{n+1} x = \gamma \beta^{-1} \alpha x \text{ where } \chi x = \psi \alpha x.$$

Calculus of
Functions.

Calculus of
Functions.

(171.) Though the reduction of any periodic function to a derivative of any other of the same order makes it obvious that no apparent generality of solution of $\psi^n x = x$ does in reality contain more than can be comprised under the form $\phi(1)^{\frac{1}{n}} \phi^{-1} x$, yet the following solution may give an idea of the variety of forms which the last-mentioned expression may contain. Let

$$\psi^n x = x \text{ and } \psi x = \phi f \phi^{-1} x,$$

or

$$\phi f^n \phi^{-1} x = x \text{ and } \phi f^n x = \phi x.$$

Let $f x$ be a periodic function of the k th order, and take ϕx any symmetrical function of

$$x, f^n x, f^{2n} x, \dots, f^{(k-1)n} x,$$

then ϕx is a solution of the preceding equation.

(172.) Questions might be proposed which occupy the same position in the Calculus of Functions with those on indeterminate equations in common Algebra. One example of such questions is contained in the following.* Let αx and βx be two rational and integral functions of the degrees m and n , having the roots

$$\begin{matrix} a_1 & a_2 & a_3 & \dots & a_m \\ b_1 & b_2 & b_3 & \dots & b_n. \end{matrix}$$

Let γx be any third function whatsoever; required solutions of the equation

$$\alpha x \phi x + \beta x \psi x = \gamma x.$$

If we signify by $\alpha' x$ and $\beta' x$ the differential coefficients of αx and βx , it follows from the theory of equations that of the quantities

$$\frac{\alpha x}{x - a_1} \cdot \frac{1}{\alpha' a_1}, \quad \frac{\alpha x}{x - a_2} \cdot \frac{1}{\alpha' a_2}, \quad \&c.$$

all disappear when x is equal to either of the series $a_1, a_2, \&c.$, except only one which becomes equal to unity; while

$$\frac{\beta x}{\beta a_1} \cdot \frac{\beta x}{\beta a_2} \quad \&c.$$

are in all those cases severally equal to unity, and vanish when x is any root of βx . Hence the expression

$$\begin{aligned} & \frac{\alpha x}{x - a_1} \cdot \frac{\beta x}{\alpha' a_1 \cdot \beta a_1} + \frac{\alpha x}{x - a_2} \cdot \frac{\beta x}{\alpha' a_2 \cdot \beta a_2} + \dots \\ & = 0 \text{ when } x \text{ is any root of } \beta x, \\ & = 1 \text{ when } x \text{ is any root of } \alpha x. \end{aligned}$$

Similarly,

$$\begin{aligned} & \frac{\beta x}{x - b_1} \cdot \frac{\alpha x}{\beta' b_1 \cdot \alpha b_1} + \frac{\beta x}{x - b_2} \cdot \frac{\alpha x}{\beta' b_2 \cdot \alpha b_2} + \dots \\ & = 1 \text{ when } x \text{ is any root of } \beta x, \\ & = 0 \text{ when } x \text{ is any root of } \alpha x; \end{aligned}$$

consequently the expression

$$\beta x \Sigma \left(\frac{\alpha x}{x - a} \cdot \frac{1}{\alpha' a \cdot \beta a} \right) + \alpha x \Sigma \left(\frac{\beta x}{x - b} \cdot \frac{1}{\beta' b \cdot \alpha b} \right)$$

is equal to unity when x is any root either of αx or βx , that is, for $m + n$ values of x . But its degree is only $m + n - 1$, therefore it cannot contain x , and must be identically equal to unity. From which it is evident, that γx multiplied by the preceding coefficients of αx and βx give ϕx and ψx the solutions of the equation.

The same process may be extended to any number of terms, thus enabling us always to give a solution of the equation

* Cauchy, *Exercices de Mathématiques*, vol. i. p. 160.

$$\Sigma(\alpha x \cdot \phi x) = \gamma x,$$

Calculus of
Functions.

where $\alpha_1 x, \alpha_2 x, \&c.$ are rational and integral functions. The distinction between this solution and any other of the infinite number which might evidently be taken consists in its always giving a rational and integral solution whenever γx is rational and integral.

(173.) Required a curve of such a nature, that any ordinate y being taken to the abscissa x , and also to an abscissa which is a given function of the first abscissa and ordinate, the second ordinate may be equal to the first abscissa.

Let $y = \psi x$ be the equation of the curve required, and let $\alpha(x, y)$ be the given function of the abscissa and ordinate. Then by the conditions, the ordinate, which has $\alpha(x, y)$ for its abscissa, is equal to x ; or

$$\psi \alpha(x, \psi x) = x.$$

Let $\psi x = \phi f \phi^{-1} x$, which gives

$$\phi f \phi^{-1} \alpha(x, \phi f \phi^{-1} x) = x,$$

or

$$\begin{aligned} \phi f \phi^{-1} \alpha(\phi x, \phi f x) &= \phi x \\ \alpha(\phi x, \phi f x) &= \phi f^{-1} x, \end{aligned}$$

which, taking any given form for f , is a common functional equation with respect to ϕ .

If, for instance, we take for $f x$ any periodic function of the second order, in which case $f^{-1} x = f x$, we can from the preceding equation deduce one of the following form,

$$\phi f x = \beta \phi x;$$

the solutions of which are discontinuous, unless β be also a periodic function of the second order; in which case we have the means of solution from (50.)

(174.) Let

$$F(x, \psi x, \psi^2 \alpha x, \psi^3 \beta x, \dots) = 0,$$

$F, \alpha, \beta, \dots$ being given forms.

Find a function ξx which does not change when $\alpha x, \beta x, \dots$ are severally substituted for x , and write $\xi^{-1} \phi \xi x$ for ψx . The equation then becomes

$$F(x, \xi^{-1} \phi \xi x, \xi^{-1} \phi^2 \xi \alpha x, \xi^{-1} \phi^3 \xi \beta x, \dots) = 0.$$

Let $y = \xi x$, which gives

$$F(\xi^{-1} y, \xi^{-1} \phi y, \xi^{-1} \phi^2 y, \dots) = 0,$$

or, ξ being known, the equation is reduced to the form

$$F_1(y, \phi y, \phi^2 y, \dots) = 0.$$

Let $\phi y = \chi f \chi^{-1} y$, f being a known form; which gives

$$F_1(y, \chi f \chi^{-1} y, \chi f^2 \chi^{-1} y, \dots) = 0,$$

or

$$F_1(\chi y, \chi f y, \chi f^2 y, \dots) = 0.$$

The solutions of this equation may be divided into two kinds: those which are periodic and those which are not periodic. If we assume for f a periodic form, then ϕ and consequently ψ must be periodic, if χ and ξ be continuous. In that case, the non-periodic values of ψ will answer to discontinuous forms of χ : conversely, if we assume f to be non-periodic, the periodic forms of ψ , if any, will answer to discontinuous values of χ . In the preceding solution, however, a point must be held in mind which considerably limits its generality. In the first substitution $\xi^{-1} \phi \xi x$, and the subsequent assumption of $\xi^{-1} \phi \xi \alpha x = \xi^{-1} \phi \xi x$, because $\xi \alpha x = \xi x$, we may be led into the mistake pointed out in (163.) Generally speaking, it must be taken as a rule that the operation ξ^{-1} performed upon ξ , whatever may have been the intermediate operations, produces a result which does

Calculus of Functions.

not possess the properties of χ performed upon ξ with intermediate operations, where χ and ξ are wholly independent. If, for instance, we were to apply the preceding reasoning to the equation

$$F(x, \psi x, \psi \alpha x \dots) = 0,$$

say, for a particular example, to

$$\psi x + \psi \alpha x = \beta x,$$

the first result of the substitution would be

$$\xi^{-1} \phi \xi x + \xi^{-1} \phi \xi \alpha x = \beta x,$$

or

$$2 \xi^{-1} \phi \xi x = \beta x,$$

from which it would appear that we could immediately determine ϕx . But the truth is, that though $\xi \alpha x = \xi x$ yet, firstly, the consequence $\phi \xi \alpha x = \phi \xi x$ is only true of those forms of ϕ which do not invert any periodic terms of ξ , and we thus perhaps throw away some forms of the solution; secondly, it does not follow that $\xi^{-1} \phi \xi \alpha x = \xi^{-1} \phi \xi x$, and indeed will not be true of most of the forms which we have found. Take, for instance, $\alpha x = a x$, and let

$$\xi x = x^{\frac{2\pi\sqrt{-1}}{\lambda a}} \quad \xi^{-1} x = x^{\frac{\lambda a}{2\pi\sqrt{-1}}}$$

Let

$$\phi x = x^2 \quad \xi^{-1} \phi \xi x = x^2 \quad \xi^{-1} \phi \xi \alpha x = \overline{a x}^2;$$

the preceding is the construction of $\xi^{-1} \phi \xi x$, &c., in the ordinary and usual meaning of the symbols of compound functions; that is, assuming $\phi \psi \chi x$ to be the same thing as $(\phi \psi) \chi x$, and $(\xi^{-1} \phi \xi) \alpha x$ to mean the same thing as $\xi^{-1} \phi (\xi \alpha x)$. It is true that, if we perform successively the operations αx , $\xi \alpha x$ (which is ξx) &c., we do arrive at the same result as $\xi^{-1} \phi \xi x$; but owing to the ambiguity of the process of inversion, we cannot say that $(\xi^{-1} \phi \xi) \alpha x = (\xi^{-1} \phi \xi) x$, where $\xi^{-1} \phi \xi$ is considered as one defined operation. But this is what is meant in the substitution of $\xi^{-1} \phi \xi x$ instead of ψx in the solution of

$$\psi x + \alpha x \psi (\alpha x) = \beta x,$$

and the introduction of the substitution without attention to this circumstance would be equivalent to confounding the preceding equation with

$$\psi x (1 + \alpha x) = \beta x.$$

(175.) The reduction of an equation to an equation of differences can be more simply done by means of the exponential inverse: and the method we now give is the same in effect as that of Laplace, the finding of the exponential inverse required answering to the first of the integrations in article (100.) Let

$$F(x, \phi \alpha x, \phi \beta x) = 0:$$

write $\alpha^{-1} x$ for x , and this becomes

$$F(\alpha^{-1} x, \phi x, \phi \beta \alpha^{-1} x) = 0.$$

Find $E x$ the exponential inverse of $\beta \alpha^{-1} x$, and assume $\phi x = \psi E x$. Then $\phi \beta \alpha^{-1} x = \psi E \beta \alpha^{-1} x = \psi (E x - 1)$. Substitute in the equation, and write $E^{-1} x$ for x , which gives

$$F\{\alpha^{-1} E^{-1} x, \psi x, \psi (x - 1)\} = 0,$$

or, writing u_x for $\psi (x - 1)$,

$$F(\alpha^{-1} E^{-1} x, u_{x+1}, u_x) = 0,$$

a common equation of differences. Similarly, if

$$F(x, \phi x, \phi \alpha x, \phi \alpha^2 x \dots \phi \alpha^n x) = 0$$

let $A x$ be the exponential inverse of αx , and let $\psi A x$ be the solution required. Then

VOL. II.

Calculus of Functions.

$$\phi \alpha x = \psi A \alpha x = \psi (A x - 1)$$

$$\phi \alpha^2 x = \psi (A \alpha x - 1) = \psi (A x - 2), \text{ \&c.}$$

Substitute these values, write $A^{-1} x$ for x , and u_x for ψx , which gives

$$F(A^{-1} x, u_x, u_{x+1}, \dots, u_{x+n}) = 0.$$

Let

$$F(x, \psi x, \psi^2 x \dots \psi^n x) = 0$$

$$F(\alpha x, \phi \alpha x, \phi \alpha^2 x \dots \phi \alpha^n x) = 0$$

where

$$\phi \alpha \phi^{-1} x = \psi x.$$

This, as before, may be reduced to

$$F(A^{-1} x, u_x, u_{x+1}, \dots, u_{x+n-1}) = 0.$$

(176.) The question of the actual solution of any given functional equation is yet far from capable of being solved, unless in a few particular cases. By observing, however, one general form, we shall be able to see to what species of processes we must look as the means of attaining the object. Let us take the general equation of the first degree

$$\phi x + \beta x \phi \alpha x = \gamma x \dots (1).$$

Firstly, two solutions of this equation can differ only by a solution of

$$\phi x + \beta x \phi \alpha x = 0 \dots (2);$$

for if ϖx and $\varpi_1 x$ both satisfy equation (1), we have

$$(\varpi x - \varpi_1 x) + \beta x (\varpi \alpha x - \varpi_1 \alpha x) = 0,$$

or $\varpi x - \varpi_1 x$ satisfies equation (2).

Again, it must be evident that if ϖx and $\varpi_1 x$ are particular solutions of (2), then $\frac{\varpi x}{\varpi_1 x}$ is also a solution of

$$\phi x - \phi \alpha x = 0 \dots (3),$$

which can readily be obtained when $A x$ is known.

The solution of equation (1) either contains one arbitrary constant only, (that is, more than is contained in αx , &c.) or an infinite number. For if it contain a finite number, let ϕx be the solution with the greatest possible number of constants. Let one of these constants be c , and differentiate both sides of (1) with respect to c , giving

$$\frac{d \phi x}{d c} + \frac{d \phi \alpha x}{d c} \cdot \beta x = 0.$$

But $\frac{d \phi \alpha x}{d c}$ is the same function of αx which $\frac{d \phi x}{d c}$ is of x ; so that $\frac{d \phi x}{d c}$ is a solution of (2), and thence

$\phi x + c' \frac{d \phi x}{d c}$ is also a solution of (1); that is, there

may be one more than the number of constants assumed, which is against the supposition. By the same reasoning it may be shown that the most general solution of (2) as to constants can have one only or an infinite number. And since the difference of any two solutions of (1) is a solution of (2), &c., the most general algebraical form of the solution of (1) is

$$\mu x + c \cdot \nu x,$$

where μx is a solution of (1), not containing a constant, and νx a solution of (2). If in this we write $\xi \alpha x$ for c , we have the most general solution, unless a solution can be given for (1) containing an infinite number of arbitrary constants.

2 Y

Calculus of
Functions.

An infinite number of arbitrary constants corresponds to an infinite number of algebraical forms different from each other, which are solutions of the equation. The same does any one constant entering in a manner which admits of the result being algebraically expanded in a series of powers of the constant. For if

$$c_1 \varpi_1 x + c_2 \varpi_2 x + \dots \text{ad inf.},$$

or

$$\varpi_0 x + \varpi_1 x \cdot c + \varpi_2 x \cdot c^2 + \dots \text{ad inf.}$$

be solutions of equation (1), in which c does not enter into αx , βx , or γx , it follows that $\varpi_0 x$, $\varpi_1 x$, &c. are severally solutions of (1). But this cannot be if $\varpi_0 x$, $\varpi_1 x$, &c. contain only the ordinary transcendents of Algebra, still less if they are common algebraical functions, as in that case $\varpi_m x$, $\varpi_n x$, and $\varpi_p x$ being solutions of (1), $\varpi_m x - \varpi_n x$ and $\varpi_n x - \varpi_p x$ are solutions of (2), and

$$\frac{\varpi_m x - \varpi_n x}{\varpi_n x - \varpi_p x} \text{ of (3);}$$

that is, the equation $\phi \alpha x = \phi x$ is solved by a function containing only the common expressions of Algebra, which, unless in the case of a periodic function, we think preceding evidence entitles us to say, cannot be; at least, never has been found so to be. This finally reduces the most general form of the algebraic solution of (1) to

$$\mu x + c \cdot \nu x,$$

where μx is the most general algebraic solution independent of new constants, and νx the same of (2). Consequently

$$\phi x = \mu x + \xi \alpha x \cdot \nu x$$

is the most general solution.

(177.) The particular solutions of (1), as found by trial or otherwise, may be of any number of forms, since, if any *specific* value be given to c , $\mu x + c \nu x$ does not contain an arbitrary constant. But the particular solutions of (2) will be all of one form, the difference being only in a constant factor. Thus in the case of

$$\phi x = \frac{x^5 - x^4}{x^3} + \frac{1}{x^3} \phi(x^3),$$

of which $x^2 + x^3$ and $x^2 - x^3$ are particular solutions, $c x^3$ is found to be the only algebraical solution of $\phi x = \frac{1}{x^3} \phi(x^3)$.

(178.) We have before seen that the theory of discontinuous functions must form the link between those of periodic and non-periodic functions. The former are, if we may so express it, the *rational quantities* of this branch of the subject, when considered in all their extent: the *whole numbers*, when the successive functions only, and not functional inverses, are considered. The discontinuous function is the *radical sign*, and is necessary to the expressing of periodic by means of non-periodic functions, and *vice versa*.

To any functional equation whatsoever, an infinite number of discontinuous solutions may be found, subject only to the condition that the solutions of continuity must take place at the values of x contained in the series

$$\dots \alpha^{-1} c, c, \alpha c, \alpha^2 c, \alpha^3 c, \dots$$

where c is any given quantity, and αx one of the functions which enters under an unknown functional symbol. For example, take the equation (1) now under consideration, and suppose, for instance, that αx increases

from $x = -\infty$ to $x = +\infty$, and let the values of αx when $x = 0$ be denoted by c_1, c_2 , &c.

Let there be a discontinuous function, which, from $x = 0$ to $x = c_1$, is ϖx , from $x = c_1$ to $x = c_2$, is $\varpi_1 x$, and so on. Assuming, therefore, A_n to represent a function of x which is unity for all values of x between c_n and c_{n+1} , and nothing for all others, let us assume

$$\phi x = A_0 \varpi x + A_1 \varpi_1 x + A_2 \varpi_2 x + \dots$$

If for x we take a value lying between c_n and c_{n+1} , we have

$$\phi x = A_n \varpi_n x \quad \phi \alpha x = A_{n+1} \varpi_{n+1} \alpha x,$$

or

$$\phi x = \varpi_n x \quad \phi \alpha x = \varpi_{n+1} \alpha x;$$

let the following conditions exist between ϖx , $\varpi_1 x$, &c.

$$\varpi x + \beta x \varpi_1 \alpha x = \gamma x$$

$$\varpi_1 x + \beta x \varpi_2 \alpha x = \gamma x, \text{ \&c.};$$

and the equation (1) is evidently satisfied for all values of x from nothing to infinity. An additional series would make the solution true for all negative values, and the generality of the solution might be further increased by supposing ϖx itself discontinuous, $\varpi_1 x$, &c. being then discontinuous in a corresponding manner.

(179.) Thus, to solve the equation $\phi(x+a) = \phi x$, let a straight line carrying points equidistant from each other by a move parallel to itself, so that one of the points moves from its first position to that of the next point, over an arc of any curve, continuous or discontinuous. Then the succession of branches so obtained is a discontinuous solution of the equation.

In the same manner, any other case of $\phi \alpha x = \phi x$ may be shown to have an infinite number of discontinuous solutions; and therefore the solution of (1) or

$$\phi x = \mu x + \xi \alpha x \cdot \nu x$$

may be subject to discontinuity in the term $\xi \alpha x$, even where the functions μx and νx are continuous.

(180.) Wherever an arbitrary constant is a part of a solution, that is to say, a constant which does not enter expressly into the conditions of the problem, it must be determined by the particular circumstances of the problem. The constant of integration is only one particular case, though the appearance of a constant is usually held almost peculiar to integration. But a wider induction from observation of solutions leads us to infer that though the solution of the problem of giving a *value* to a *form* does not introduce a constant, yet the latter must always be looked for where the object is to assign *forms* which stand in specified relations to other *forms*.

By the term constant we see that we now mean any function whatsoever which does not change under any changes which are supposed in the equation, or which become necessary to be considered in the actual verification of the conditions of the problem. In the Differential Calculus only is this constant absolutely constant in the primitive sense of the term, the reason being, that every possible continuous change is undergone by the variable, and the constant must therefore satisfy $\Delta c = 0$ for every value of the difference of the variable. In the Calculus of *Finite Differences*, (which perhaps analogy may at a future time denominate *discontinuous differences*), the condition is $\Delta c = 0$ for given *finite* values of the difference of the variable. In the Calculus of Functions the condition is $\Delta c = 0$ for given *changes of form* of the variable. And this, it must be observed, may lead us,

Calculus of
Functions.

Calculus of Functions. since any manner of satisfying the conditions is a solution, to either of the following species of arbitrary constants.

1. A continuous function of x , unchanged when x is changed into αx , βx , &c.
2. A discontinuous function of the same kind.
3. A continuous constant, that is to say, a constant in the primitive notion of the word.
4. A discontinuous constant, that is, a discontinuous function of x , which only so far depends upon x , as certain values of the latter mark the epochs of the solutions of continuity.*

(181.) The last-mentioned sort of constant, being of a somewhat unusual character, requires some discussion. The question is, can the equation $\phi \alpha x = \phi x$ be satisfied by a function of x , which is

$$\begin{aligned} & \dots \dots \dots \\ c_1 & \text{ from } x = -a_2 \text{ to } x = -a_1 \\ c_0 & \text{ from } x = -a_1 \text{ to } x = 0 \\ c_2 & \text{ from } x = 0 \text{ to } x = a_2 \\ & \dots \dots \dots \end{aligned}$$

or the like? It is obvious that this will be the case for such limits as contain αx and x between them at the same time. For, calling c_x the constant in question, if a_1 and a_2 be values of x between which c_x remains the same, then $c_{\alpha x} = c_x$ will be true if αx be between the limits when x is so. Or rather this should be extended as follows. If there be any number of values $a_1, a_2, a_3, \dots$, ranged in order of magnitude, and having this property, that when x lies any where between any two consecutive values, αx lies either in the same interval, or entirely in some other, then the constant may be made discontinuous, provided it always have the same value in the intervals in which x and αx are simultaneously found. And if this can be partially done, the arbitrary function may be made discontinuous, being constant for the intervals just mentioned, and otherwise continuous or discontinuous in all other intervals.

The condition may be simply represented geometrically (fig. 2) as follows. Take any origin O , and draw a line OA inclined at an angle of 45° to rectangular axes of coordinates. Take any points in this line, and through them draw intersecting parallels to the axes. Then if the curve whose ordinate is αx cut these lines in intersections of the parallels, the preceding conditions are fulfilled wholly or partially, except where the diagonal curve and diagonal right line are in immediately contiguous rectangles. For the higher curve in figure 2, the dotted lines on the same level denote intervals in which the constants must be the same. For the lower curve the constant must be the same in the interval

* A distinguished analyst calls Algebra the science of pure time, as Geometry is that of pure space. The notions of time, succession, and number are so nearly related that we have no doubt very admissible conventions would make this palpably true. In the mean while we are very glad to avail ourselves of such an authority to introduce a most convenient term. We have always regretted the loss of the metaphysics of fluxions, which there was no necessity for discarding with the notation. Admit the following definition—Time is the succession of values of the independent variable; so that a condition is said to be satisfied at an earlier or a later time, according as it is satisfied for a greater or less (or less or greater) value of the independent variable—and the language of Algebra will be materially facilitated. If all the circumlocutions by which English mathematicians have of late years endeavoured to prove themselves free from the notion of successive values being given in successive times were collected together, we should write in the title-page "*corrigenda aut potius vitanda*."

between the two intersections with the diagonal line, and may take another value for all greater values of x , positive or negative. In figure 3 there may be discontinuity in the constant in the manner indicated by the dotted lines. It must be observed, however, that it is not in this arbitrary way that a discontinuous function can be made constant in all the several intervals of continuity, throughout the complete scale of magnitude, from $-\infty$ to $+\infty$. The general determination of this question is a problem of considerable difficulty, amounting to the following. Required a scale of magnitudes

$$\dots a_{-1} \ a_0 \ a_1 \ a_2 \dots$$

proceeding from $-\infty$ to $+\infty$, and such that

$$(x - a_n)(x - a_{n+1}) \text{ and } (\alpha x - a_{n+m})(\alpha x - a_{n+m+1})$$

may always be negative together, continuous or discontinuous relations existing between n and m , but such that no interval may be missing.

(182.) We shall now take some algebraical examples of these discontinuous constants. And first we ask what discontinuous constant satisfies $\phi \log x = \phi x$. If x be less than 1, so is $\log x$; but if x be greater than 1, $\log x$ is not always so. In fact, the condition cannot in any way be completely satisfied, except where the constant is altogether continuous.

Secondly, let $\phi x^m = \phi x$, m being a positive integer. Here, when x lies between $+1$ and -1 , x^m has the same limits, while from $x = -1$ to $x = -\infty$, and from $x = +1$ to $x = +\infty$, x^m has the same limits when m is odd, and the latter limits when m is even. Hence, when m is even, the discontinuous constant is

$$C_{-\infty, -1} + C'_{-1, +1} + C_{+1, +\infty},$$

meaning by $C_{-\infty, -1}$ a constant which is C for all values between $-\infty$ and -1 , and zero for all others. When m is odd, the most general solution is

$$C_{-\infty, -1} + C'_{-1, 0} + C''_{0, +1} + C'''_{+1, \infty}.$$

Thirdly, the solution of $\phi(a + bx) = \phi x$ is

$$C_{-\infty, \frac{a}{1-b}} + C'_{\frac{a}{1-b}, +\infty}.$$

Fourthly, both $\sin x$ and x lie between 0 and ∞ , when x lies between 0 and π , 2π and 3π , &c., and between 0 and $-\infty$ when x lies between 0 and $-\pi$, -2π and -3π , &c. A solution of $\phi \sin x = \phi x$ is

$$\begin{aligned} & C_{-2m\pi, -(2m+1)\pi} + C_{(2m+1)\pi, (2m+2)\pi} \\ & + C'_{2m\pi, (2m+1)\pi} + C'_{-(2m+1)\pi, -(2m+2)\pi}. \end{aligned}$$

(183.) For those values of x which satisfy the equation $\alpha x = x$, the constant may possibly assume what we may call a single value belonging to that one value of x only, and totally independent of the preceding and following values. Thus, when m is an even whole number, the values of the constant which satisfies $\phi x^m = \phi x$ may be single, for $x = 0$ and $x = 1$, and the discontinuous constant may be written thus,

$$C_{-\infty, -1} + C'_{-1, 0} + C''_0 + C'_{0, +1} + C'''_{+1} + C_{+1, +\infty}.$$

(184.) We shall not here attempt application of the preceding theory to the case of impossible values of x , but shall proceed to show that what we have done is as necessary to the complete understanding of a functional equation as the arbitrary constant to that of a differential equation, and for the same reasons.

The developement of a given function into any finite series of terms is a direct operation, not admitting more ambiguity of expression than is contained in the function itself which is to be developed. The same may be said

Calculus of Functions. of the envelopement of a finite series of terms; these being direct and inverse operations of which either may be assumed as direct, the question being the same in both. But the developement of a function in an infinite series of terms involves the inverse operation of envelopement, with the consideration of a remainder, unknown both in form and magnitude, except by its developement. If this remainder be to be determined by a functional equation, and directly or indirectly many are so determined, an arbitrary constant may enter the solution, and the process may be vitiated if its existence be unknown, as has repeatedly happened. If the remainder be that of a convergent series, and diminishing without limit as the number of preceding terms is increased without limit, the constant being neglected, this does not make the last-mentioned constant, if entering by itself, diminish without limit. On the contrary, it is rather in a divergent series that an independent constant term may be neglected; and it happens, in fact, to be the case, that series which are or may be divergent present fewer difficulties in this respect than those which are always convergent. But in the case of a divergent series the form of the remainder is independent of the magnitude of the quantity, and the arbitrary constant must not be neglected.

Some writers have rejected divergent series, on account of the difficulties to which they are subject. But we shall endeavour to make it appear likely that series which are *never* divergent should be much more cautiously used. Or rather we should say, that this has been already taught in the case of series arising from the inversion of periodic series, such as those for the sine, cosine, &c., and that it may be useful to make the same more apparent in the case of other series.

The difficulties which lie in the way of the solution of functional equations will render it impossible to apply the preceding method in its full extent. But whereas it has been usual to search both for the form of the constant, (that is, to determine the intervals of continuity, where discontinuity has been proved or suspected,) and its values from the circumstances of each particular case, the preceding method may be made useful in pointing out the former, in cases where the determination of the required envelopement is not possible. But we shall give an instance, to show that the method does explain some of the circumstances which have occasioned perplexity in treating of series. The first example will show that the constant of the calculus of finite differences is a particular case.

(185.) Let

$$\psi x = \beta x (1 + \psi \alpha x),$$

which is evidently the functional equation from which the envelopement of the following series may be obtained,

$$\beta x + \beta x \beta \alpha x + \beta x \beta \alpha x \beta \alpha^2 x + \dots$$

Similarly

$$\psi x = \beta x + \psi \alpha x$$

gives

$$\psi x = \beta x + \beta \alpha x + \beta \alpha^2 x + \dots,$$

and

$$\psi x = \beta x + \gamma x \psi \alpha x$$

gives

$$\psi x = \beta x + \gamma x \beta \alpha x + \gamma x \gamma \alpha x \beta \alpha^2 x + \dots$$

Let $\alpha x = x + 1$. It will be found that $\phi(x+1) = \phi x$ cannot be satisfied by any but a *periodically* discontinuous constant. Let h be any given value of x , and m being a whole number, positive or negative, let the value of the constant be C between the limits $h + m$

and $h + m + \frac{1}{2}$, and C' between $h + m + \frac{1}{2}$ and $h + m + 1$. This is expressed by

$$C_{h+m, h+m+\frac{1}{2}} + C'_{h+m+\frac{1}{2}, h+m+1}$$

Consequently the solution of every equation of finite differences of the usual form may contain a discontinuous constant of this species, in which it is worthy of remark that the determination of the epochs of discontinuity contains an arbitrary constant.

(186.) Next, let $\alpha x = x^2$. The equation $\phi x^2 = \phi x$ may be solved by a discontinuous constant of the form

$$C_{-\infty, -1} + C'_{-1, 0} + C''_0 + C'_{0, +1} + C'''_{+1} + C_{+1, \infty},$$

these being what we have called single values when $x = 0$, and when $x = 1$.

Let us consider the equation

$$\phi x = \frac{x}{1+x^2} (1 + \phi x^2)$$

a particular solution of which is x . Another particular solution is $\frac{1}{x}$ (177.); but we find a solution of

$$\phi x = \frac{x}{1+x^2} \phi(x^2)$$

$$\phi x = x - \frac{1}{x},$$

and hence the general solution of the equation (as to continuous constant solutions of $\phi x^2 = \phi x$) is

$$\phi x = x + c \left(x - \frac{1}{x} \right);$$

the developement of ϕx in a series is as follows,

$$\phi x = \frac{x}{1+x^2} + \frac{x}{1+x^2} \cdot \frac{x^2}{1+x^4} + \frac{x}{1+x^2} \cdot \frac{x^2}{1+x^4} \cdot \frac{x^4}{1+x^8} + \dots$$

which presents several curious circumstances. It is always convergent, is not periodic for possible values of x , is a symmetrical function (apparently) of x and $\frac{1}{x}$, while the envelopement of it cannot be so, even if we take the most general of the solutions which we have found, namely,

$$x + \left(x - \frac{1}{x} \right) \theta \cos 2\pi \frac{\lambda^2 x}{\lambda^2}.$$

The value of the series may to all appearance be determined by common Algebra as follows. Divide ϕx by $1 - x^2$, which gives

$$\frac{\phi x}{1-x^2} = \frac{x}{1-x^4} + \frac{x^3}{1-x^8} + \dots = \sum \frac{x^{2^m-1}}{1-x^{2^{m+1}}},$$

which will be found by developing each term to be

$$x + x^3 + x^5 + \dots \text{ad infinitum,}$$

for

$$2^{m+1} \times 2n + 2^m - 1$$

can be easily shown to be equal to a given odd number for only one whole value of m and n . That is, we have

$$\frac{\phi x}{1-x^2} = \frac{x}{1-x^2} \quad \phi x = x:$$

but proceeding in precisely the same manner to develop each term in powers of $\frac{1}{x}$ we find that

Calculus of Functions.

$$\frac{\phi x}{1-x^2} = x^{-1} + x^{-3} + \dots \text{ or } \phi x = \frac{1}{x}.$$

But at the same time, the series being always convergent, we may easily find by summation that it fulfils the following conditions:

$$\begin{aligned} \text{when } x \text{ lies between } \pm 1 \quad \phi x &= x \\ \text{when } x = 0 \quad \phi x &= 0 \\ \text{when } x > 1 \text{ or } < -1 \quad \phi x &= \frac{1}{x}. \end{aligned}$$

If we now proceed to determine the discontinuous constant, we may do it, knowing the epochs of discontinuity, by observing that, as x diminishes or increases

without limit, $\frac{\phi x}{x}$ and $x \times \phi x$ have the limit 1. Assuming, therefore, the expression

$$x + c \left(x - \frac{1}{x} \right),$$

we see that, since the only changes of the constant (the single value excepted) take place at $x = +1$ and $x = -1$, the value of the constant must be expressed by

$$(-1)_{-\infty, -1} + (0)_{-1, +1} + (-1)_{+1, +\infty} + (0)_0,$$

in which, as it happens, it is unnecessary to express the single value. And this confirms what precedes.

(187.) The principle in which the preceding process differs from common Algebra is in the adoption of an axiom which may be thus stated: *discontinuous functions are to be admitted as solutions of an equation, when they satisfy its conditions.* All the rest is a necessary consequence of ordinary reasoning. This axiom is already admitted and used in various parts of Mathematics; and is, in fact, tacitly allowed in the explanation which is usually given of the above. Let

$$V^2 - a_n V + b_n = 0$$

be the equation whose roots are x^n and y^n . Then

$$\begin{aligned} x &= \frac{b_1}{a_1} + \frac{1}{a_1} x^2 = \frac{b_1}{a_1} + \frac{1}{a_1} \frac{b_2}{a_2} + \frac{1}{a_1 a_2} x^4, \text{ \&c.} \\ &= \frac{b_1}{a_1} + \frac{b_2}{a_1 a_2} + \frac{b_4}{a_1 a_2 a_4} + \frac{b_8}{a_1 a_2 a_4 a_8} + \text{\&c.} \end{aligned}$$

By similar reasoning, and neglecting the remainder, y may be expanded into the same series; which is, therefore, an analytical representation of either root. If

$y = \frac{1}{x}$, this series becomes the preceding; and, as in all

other cases yet observed, though it represents either root, gives the *least* root by arithmetical approximation. This theorem, namely, that the development of an ambiguous function gives, arithmetically considered, the least of the values of the envelopment, has never, so far as we know, been generally proved. Generally speaking, divergency has been the consequence of an attempt to expand any other value, but in the preceding instance this is not the case. And the same occurs in cases of infinitely continued fractions, the envelopment of which is generally ambiguous, the arithmetical value of the continued fraction always giving the least of the values.

(188.) As another example, take the case of

$$\phi x = \frac{1}{1+x} \phi x^2.$$

The solution of which is $C(1-x)$, where C may be subject to the same discontinuity as before. If we consider the continued product

$$\frac{1}{1+x} \cdot \frac{1}{1+x^2} \cdot \frac{1}{1+x^4} \dots \text{ ad inf.,}$$

or

$$\frac{1-x}{1-x^2} \frac{1}{1+x^2} \dots \text{ or } \frac{1-x}{1-x^\infty},$$

we see that it is $1-x$ for all values of x lying between -1 and $+1$, and 0 for all others. This confirms the solution derived from the functional equation, which is

$$\{(1)_{-1, +1} + (0)_{-\infty, -1} + (0)_{+1, +\infty}\} (1-x).$$

(189.) From what precedes we may gather that the discontinuous constant (for all discontinuously variable functions may be reduced to functions involving discontinuous constants) supplies the place of the symbols of ambiguity in Algebra, in cases where the generality of any unknown form prevents the ambiguity from being explicitly considered: and also that the epochs of discontinuity may be determined from the known functions of which unknown functions enter.

The discontinuity of the arbitrary function which enters the solution of a partial differential equation has long been allowed to be possible; but we are not aware that the possible discontinuity of the constant of integration has received any attention. But the fundamental difference of a common functional symbol and a differential coefficient renders it unlikely that the last-mentioned branch of the subject will present very perceptible analogies with that just considered.

(190.) We shall now proceed to consider the difficulties which stand in the way of actually finding particular solutions of the equations

$$\psi x = \beta x + \gamma x \psi \alpha x \dots (1)$$

$$\psi x = \gamma x \psi \alpha x \dots (2),$$

corresponding to the equations of differences

$$u_x = \beta A^{-1} x + \gamma A^{-1} x u_{x-1}$$

$$u_x = \gamma A^{-1} x u_{x-1}.$$

As all that has hitherto preceded seems to point out the difficulty, perhaps impossibility, of making any progress, except in cases which admit of $\alpha^n x$ being expressed as an explicit function of n , we shall assume this operation as fundamental in the case of all positive and negative whole values of n . That is, we shall assume the exponential inverse Ax to be given when the form of αx is given.

(191.) All functions may be divided into three classes.

1. Periodic functions of a finite order, which satisfy the equation $\alpha^n x = x$ for some whole value of n .

2. What we will call periodic functions of an infinite order, being those in which $\alpha^n x$ has a finite limit when n increases without limit. For, as we have shown in (37.), the limit in question is a solution of $\alpha x = x$, and gives $\alpha \alpha^n x = x$ when n is infinite.

3. Functions in which $\alpha^n x$ increases or decreases without limit, $x = \infty$ or $x = 0$ not being a root of $\alpha x = x$, and which therefore have no periodic character whatsoever.

(192.) In the first of these cases, equation (1) admits of absolute solution. We have already had an instance (137.): the general method (which is due to Mr. Babbage) being, if $\alpha^n x = x$, eliminate $\psi \alpha x, \psi \alpha^2 x, \dots \psi \alpha^{n-1} x$, from the equations

Calculus of
Functions.

$$\begin{aligned}\psi x &= \beta x + \gamma x \psi \alpha x \\ \psi \alpha x &= \beta \alpha x + \gamma \alpha x \psi \alpha^2 x \\ &\vdots \\ \psi \alpha^{n-1} x &= \beta \alpha^{n-1} x + \gamma \alpha^{n-1} x \psi x,\end{aligned}$$

giving

$$\psi x = \frac{\beta x + \gamma x \beta \alpha x + \gamma x \gamma \alpha x \beta \alpha^2 x + \dots + \gamma x \dots \gamma \alpha^{n-2} x \beta \alpha^{n-1} x}{1 - \gamma x \gamma \alpha x \gamma \alpha^2 x \dots \gamma \alpha^{n-1} x}$$

When the numerator and denominator are both finite, no arbitrary constant can enter; for a solution of $\phi x = \gamma x \phi \alpha x$ gives

$$1 = \gamma x \gamma \alpha x \dots \gamma \alpha^{n-1} x,$$

which makes the denominator of the preceding infinite. Excepting discontinuous solutions, we have here then the complete and only solution. But it must be observed, that the discontinuous function is of the species noticed in (72.), and the method might be extended to this case.

(193.) In what follows, we mean by P_0, α_0 , &c., functions of x ; by P_1, α_1 , &c. the corresponding functions of αx , and so on. So that the solution of

$$P_0 = B_0 + c_0 P_1 \quad (\alpha^n x = x) \dots (1)$$

is

$$P_0 = \frac{B_0 + c_0 B_1 + c_0 c_1 B_2 + \dots + c_0 c_1 \dots c_{n-2} B_{n-1}}{1 - c_0 c_1 c_2 \dots c_{n-1}}.$$

The denominator of this solution must vanish whenever the numerator vanishes, except only when $B_0 = 0$. For if the numerator vanish without the denominator, $P_0 = 0, P_1 = 0$, and therefore $B_0 = 0$. But this appears more clearly by observing that the first of the following equations gives all the rest, and that they give an equation of condition among c_0, c_1 , &c. For simplicity, we suppose the periodic function to be of the fourth order, ($c_4 = c_0, B_4 = B_0$, &c.)

$$\begin{aligned}B_0 + c_0 B_1 + c_0 c_1 B_2 + c_0 c_1 c_2 B_3 &= 0 \\ B_1 + c_1 B_2 + c_1 c_2 B_3 + c_1 c_2 c_3 B_0 &= 0 \\ B_2 + c_2 B_3 + c_2 c_3 B_0 + c_2 c_3 c_0 B_1 &= 0 \\ B_3 + c_3 B_0 + c_3 c_0 B_1 + c_3 c_0 c_1 B_2 &= 0.\end{aligned}$$

Now there cannot be two perfectly independent relations between c_0, c_1 , &c., which reconcile the preceding, for if there be two such, namely $V_0 = 0$ and $W_0 = 0$, then $V_1 = 0$ and $W_1 = 0$ fulfil the same conditions, and so on; that is, there are more than $n-1$, namely $(2n-2)$ conditions among c_0, c_1 , &c., and they cease to be indeterminate. Except only when both V_0 or W_0 are symmetrical functions of c_0, c_1 , &c., or else when the two are connected by an equation of the form

$$f(V_0, W_0) = \xi \alpha x.$$

Therefore if one of the two be a symmetrical function of c_0, c_1 , &c. (or a form of $\xi \alpha x$), both are so. Now

$$1 - c_0 c_1 c_2 c_3 = 0$$

makes the preceding equations identical, as appears by substituting in either the reciprocal of the one omitted in the last term for the product of all the rest. It is therefore the sole condition under which the preceding equations can be true, which may be verified by actual solution.

When the denominator of P_0 vanishes without the numerator, it is a sign that there is no continuous solution whatsoever; in fact, the last-mentioned condition combined with the equation (1) will be found to give an equation of condition, namely, that the function in the

numerator of P_0 shall be nothing. It may also be easily shown that the condition $1 - c_0 c_1 \dots c_{n-1} = 0$ is required in order that $P_0 = c_0 P_1$ may be possible.

(194.) Given αx , required values of c_0, c_1 , &c., which will satisfy the condition

$$1 - c_0 c_1 \dots c_{n-1} = 0.$$

It is evident that

$$c_0 = \frac{m_0}{m_0 + m_1 + m_2 + \dots + m_{n-1}}$$

satisfies the condition

$$c_0 + c_1 + c_2 + \dots + c_{n-1} = 1:$$

that

$$\frac{m_0}{\sum m_0} - \frac{p_0}{\sum p_0}$$

therefore makes the same sum = 0; or that

$$\frac{m_0}{\sum m_0} - \frac{p_0}{\sum p_0} = c_0$$

satisfies the condition in question; and the exponent may be multiplied by any form of $\xi \alpha x$, or any symmetrical function of $x, \alpha x \dots \alpha^{n-1} x$.

(195.) We may integrate the equation

$$P_0 = c_0 P_1,$$

the preceding condition being fulfilled, as follows. Let the degree of the function be the fourth, and assume

$$\begin{aligned}P_0 &= 1 + c_0 + c_0 c_1 + c_0 c_1 c_2 \\ P_1 &= 1 + c_1 + c_1 c_2 + c_1 c_2 c_3 \\ c_0 P_1 &= c_0 + c_0 c_1 + c_0 c_1 c_2 + 1 = P_0,\end{aligned}$$

whence

$$P_0 = (1 + c_0 + c_0 c_1 + c_0 c_1 c_2) \xi \alpha x$$

is the general solution of $P_0 = c_0 P_1$.

(196.) Given c_0 , so that $c_0 c_1 c_2 c_3 = 1$ required solutions of

$$B_0 + c_0 B_1 + c_0 c_1 B_2 + c_0 c_1 c_2 B_3 = 0 \quad (\alpha^4 x = x).$$

If we assume the first of the succeeding equations, we have those which follow:

$$\begin{aligned}B_0 &= V + V' c_0 + V'' c_0 c_1 + V''' c_0 c_1 c_2 \\ c_0 B_1 &= V c_0 + V' c_0 c_1 + V'' c_0 c_1 c_2 + V''' \\ c_0 c_1 B_2 &= V c_0 c_1 + V' c_0 c_1 c_2 + V'' + V''' c_0 \\ c_0 c_1 c_2 B_3 &= V c_0 c_1 c_2 + V' + V'' c_0 + V''' c_0 c_1,\end{aligned}$$

whence the equation in question is satisfied if

$$V + V' + V'' + V''' = 0,$$

these being severally symmetrical functions of $x, \alpha x, \alpha^2 x$, and $\alpha^3 x$.

The preceding process fails when $c_0 = 1$, by giving only the solution $B_0 = 0$; but in that case we have, as before,

$$B_0 = \frac{p_0}{\sum p_0} - \frac{q_0}{\sum q_0}.$$

(197.) Let us now take the equation

$$\phi x = \beta x + \gamma x \phi \alpha x \quad (\alpha^4 x = x) \dots (\phi),$$

or

$$P_0 = B_0 + c_0 P_1,$$

where

$$\begin{aligned}B_0 + c_0 B_1 + c_0 c_1 B_2 + c_0 c_1 c_2 B_3 &= 0 \dots (B) \\ 1 - c_0 c_1 c_2 c_3 &= 0 \dots (c)\end{aligned}$$

Assume

$$P_0 = Q_0 (1 + c_0 + c_0 c_1 + c_0 c_1 c_2) = Q_0 C_0, \quad B_0 = B'_0 C_0,$$

which makes (ϕ) become

$$Q_0 C_0 = B'_0 C_0 + C_0 Q_1,$$

or

$$Q_0 = B'_0 + Q_1.$$

Calculus of
Functions.

Calculus of Functions. And because C_0 is a solution of $P_0 = c_0 P_1$, the condition (B) gives

$$B'_0 + B'_1 + B'_2 + B'_3 = 0.$$

Assume $Q_0 = m B'_0 + m' B'_1 + m'' B'_2$,
giving $\left. \begin{matrix} m B'_0 \\ + m' B'_1 \\ + m'' B'_2 \end{matrix} \right\} = B'_0 + \left\{ \begin{matrix} m B'_1 \\ + m' B'_2 \\ + m'' (-B'_0 - B'_1 - B'_2) \end{matrix} \right\}$,
which is satisfied by making

$$m = 1 - m'' \quad m = \frac{3}{4}$$

$$m' = m - m'' \quad m' = \frac{2}{4}$$

$$m'' = m' - m'' \quad m'' = \frac{1}{4},$$

or

$$Q_0 = \frac{1}{4} (3 B'_0 + 2 B'_1 + B'_2)$$

$$P_0 = Q_0 C_0 = \frac{C_0}{4} \left(3 \frac{B_0}{C_0} + 2 \frac{B_1}{C_1} + \frac{B_2}{C_2} \right).$$

This is only a particular solution, but it may be made general by adding $C_0 \xi \alpha x$, the general solution of $P_0 = c_0 P_1$, which gives

$$P_0 = \frac{C_0}{4} \left(3 \frac{B_0}{C_0} + 2 \frac{B_1}{C_1} + \frac{B_2}{C_2} \right) + C_0 \xi \alpha x \\ = \frac{1}{4} (3 B_0 + 2 c_0 B_1 + c_0 c_1 B_2) + C_0 \xi \alpha x.$$

And the solution of the same equation, when αx is of the n th order, and the conditions are altered accordingly, is

$$P_0 = \frac{1}{n} \{ \overline{n-1} B_0 + \overline{n-2} c_0 B_1 + \dots + c_0 c_1 \dots c_{n-2} B_{n-2} \} \\ + (1 + c_0 + c_0 c_1 + \dots + c_0 c_1 \dots c_{n-2}) \xi \alpha x.$$

In the case of a periodic function of the second order the preceding assumes the form

$$P_0 = \frac{1}{2} \beta x + (1 + \gamma x) \xi \alpha x,$$

and B_0 must be of the form $V - V \gamma x$, where V is a symmetrical function of x and αx , or it may be of γx

and $\gamma \alpha x$, that is, of γx and $\frac{1}{\gamma x}$. If we assume

$$V = \frac{\sqrt{-\gamma x}}{1 - \gamma x} \xi \alpha x$$

we may get the form of solution given by Mr. Babbage, (*Examples, &c.*, p. 21.)

The preceding solution, in an equivalent form, might be obtained by finding $V, V', &c.$ from the equations

$$B_0 = V + V' c_0 + \dots$$

$$B_1 = V + V' c_1 + \dots$$

$$\dots$$

and solving the equation

$$P_0 = V + V' c_0 + \dots + c_0 P_1$$

by such an assumption as

$$P_0 = W + W' c_0 + \dots$$

(198.) We now come to the second of the cases mentioned in (191.), namely, where αx is a periodic function of an infinite order, as we have called it by

extension, namely, where $\alpha^n x$ has a finite limit when n increases without limit. The analogy is not very perfect, because the infinitely periodic function, instead of approximating to the value of x first set out with, approximates to a determinate value of x , namely, a root of $\alpha x = x$. Nor have we any method of solution in this case which cannot also be applied to the third species of functions in (191.) We shall, therefore, confine what we have to say on infinitely periodic functions to this article, and then drop the name.

Let p be a root of $\alpha x = x$. Then, since some values of x always make $\alpha^n x$ approximate to p (we have found this by observation), and since the equation

$$\phi x = \beta x + \gamma x \phi \alpha x$$

gives

$$\phi \alpha^n x = \beta \alpha^n x + \gamma \alpha^n x \phi \alpha^{n+1} x,$$

the reasoning of (37.) shows that we must have

$$\phi p = \beta p + \gamma p \phi p,$$

or

$$\phi p = \frac{\beta p}{1 - \gamma p},$$

and if $\gamma p = 1$, ϕp is infinite or $\beta p = 0$. Again, if there be an arbitrary function in the solution, then $\phi x = \gamma x \phi \alpha x$ must admit of solution, or $\phi p = \gamma p \phi p$, and either ϕp is nothing or infinite, or $\gamma p = 1$. Such reasoning as the above is worth little, except as an index to the sort of methods which are probably good, in attempting to solve an equation of the kind specified. We have found it confirmed by instances in which the equation was formed from a given algebraical solution, as follows: the equation of the form in question, which has the solution $\mu x + \nu x \cdot \xi \alpha x$ is

$$\phi x = \frac{\mu x \cdot \nu \alpha x - \mu \alpha x \nu x}{\nu \alpha x} + \frac{\nu x}{\nu \alpha x} \cdot \phi \alpha x,$$

in all the cases in which νp is finite, we have $\gamma p = 1$ and $\beta p = 0$; while $\nu p = 0$ gives $\frac{1}{\alpha' p}$ for the value of γp , and $\mu p \left(1 - \frac{1}{\alpha' p} \right)$ for that of βp .

(199.) A process similar to that employed in the case of periodic functions gives (using the same denominations as before, namely, $P_0 = \phi x \quad B_0 = \beta x \quad c_0 = \gamma x \quad P_1 = \phi \alpha x$, &c.)

$$P_0 - c_0 P_1 = B_0$$

$$P_0 - c_0 c_1 P_2 = B_0 + c_0 B_1$$

$$P_0 - c_0 c_1 c_2 P_3 = B_0 + c_0 B_1 + c_0 c_1 B_2, \&c.$$

Or if

$$\varpi_n = c_0 c_1 c_2 \dots c_n$$

$$P_0 - \varpi_n P_{n+1} = B_0 + \varpi_0 B_1 + \varpi_1 B_2 \dots + \varpi_{n-1} B_n.$$

Consequently, in forming the series from a given involution, the true arithmetical value is

$$\phi x - \varpi_\infty \phi p \dots (\varpi),$$

and is only ϕx where $\varpi_\infty \phi p = 0$. But in obtaining the involution from the solution of the functional equation, we need not attend to any correction of the general value of ϕx ; for ϖ_∞ is a solution of $P_0 = c_0 P_1$, and the second term of (ϖ) may be considered as a part of $\nu x \xi \alpha x$ in the complete solution $\mu x + \nu x \xi \alpha x$. But we here see reason to confirm the entry of a *discontinuous constant* rather than a *discontinuous variable function*, into the form of the solution of the general equation, which gives the involution of the above-

Calculus of
Functions.

mentioned series. For different values of x may cause the limits of $\alpha^n x$ to be different roots of $\alpha x = x$, or may make it increase without limit. And since there can be but one solution (really algebraical) of $\phi x = \gamma x \phi \alpha x$, in all cases where the continued product ϖ_∞ is algebraical, it is the solution in question: whence if p_1, p_2, p_3 , &c. be the several roots of p , the preceding term must have the form

$$(C_1 \phi p_1 + C_2 \phi p_2 + \dots) \varpi_\infty,$$

where C_1, C_2 severally disappear for all values of x , except those which lie between certain limits. This also tends to establish what we have hitherto observed, namely, that among the epochs of discontinuity are the arithmetical values which satisfy $\phi x = x$.

(200.) The same considerations apply to the integration of equations of differences of the form

$$u_x = B_x + G_x u_{x-1};$$

but the case which has been completely resolved, namely, where αx is a periodic function, gives only equations of differences which involves discontinuous functions (in value), as appears from (64.) and the reduction of

$$\phi x = \beta x + \gamma x \phi \alpha x \text{ in (175.)},$$

which is

$$u_x = \beta A^{-1} x + \gamma A^{-1} x u_{x-1}.$$

(201.) We proceed to point out some cases in which the general functional equation of the first degree, containing one unknown function of a known function, is integrable on the supposition that Ax is given when αx is given. The equation

$$\phi x = \alpha' x \phi \alpha x$$

is integrable, where $\alpha' x$ is the differential coefficient of αx .

The general solution is $A'x \xi \alpha x$. For the differentiation of both sides of the equation

$$A \alpha x = A x - 1$$

gives

$$A' \alpha x \cdot \alpha' x = A' x,$$

or $A'x$ is a particular solution of the equation in question. Thus, to integrate

$$\phi x = 2 x \phi x^2,$$

we find that if

$$\alpha x = x^2, A x = -\frac{\lambda^2 x}{\lambda 2}, A' x = -\frac{1}{\lambda 2 \cdot x \lambda x},$$

or

$$\phi x = -\frac{1}{\lambda 2 \cdot x \lambda x} \cdot \theta \cos 2\pi \frac{\lambda^2 x}{\lambda 2}.$$

Denoting the differential coefficient of ϕx by $D \phi x$, we find in the same way, that

$$\phi x = \frac{D \alpha^m x}{D \alpha^n x} \phi \alpha^{m-n} x$$

gives

$$\phi x = A' \alpha^n x \cdot \xi \alpha x,$$

because

$$A \alpha^n x = A \alpha^m x + m - n.$$

We have also

$$D \alpha^m x = D \alpha \cdot \alpha^{m-1} x \cdot D \alpha \cdot \alpha^{m-2} x \dots D \alpha x,$$

where $D \alpha$ is considered as one functional symbol.

(202.) The equation $\phi x = A x \phi \alpha x$ can be solved in the form of a definite integral only. Let $\phi x = \chi A x$, giving

$$\chi A x = A x \chi A \alpha x = A x \chi (A x - 1)$$

or

$$\chi x = x \chi (x - 1),$$

whence

$$\phi x = \int e^{-x} a^{Ax} da, \text{ from } a = 0 \text{ to } a = \infty;$$

here χx is what is usually denoted by Γx .

(203.) If $\varpi_1 x$ and $\varpi_2 x$ be particular solutions of the equations

$$\phi x = \gamma_1 x \phi \alpha x \quad \phi x = \gamma_2 x \phi \alpha x,$$

then $\varpi_1 x \cdot \varpi_2 x$ and $\frac{\varpi_1 x}{\varpi_2 x}$ are particular solutions of

$$\phi x = \gamma_1 x \gamma_2 x \phi \alpha x \quad \phi x = \frac{\gamma_1 x}{\gamma_2 x} \phi \alpha x.$$

From this we find that

$$\phi x = (D \alpha x)^n \phi \alpha x \text{ gives } \phi x = (D A x)^n \xi \alpha x,$$

and since $\phi x = c \phi \alpha x$ gives $\phi x = c^{Ax}$

$$\phi x = c (D \alpha x)^n \phi \alpha x \text{ gives } \phi x = c^{Ax} (D A x)^n \cdot \xi \alpha x.$$

(204.) From the solution of $\phi x = \gamma x \phi \alpha x$ immediately follows that of $\phi x = \gamma \alpha_1 x \phi \alpha x$, where $\alpha_1 x$ is any function which is convertible with αx . For if ϖx solve the first equation, then $\varpi \alpha_1 x = \gamma \alpha_1 x \varpi \alpha_1 x = \gamma \alpha_1 x \varpi \alpha_1 \alpha x$ or $\varpi \alpha_1 x$ solves the second equation. Thus, having got a particular solution of

$$\phi x = \frac{1}{1+x} \phi (x^2),$$

namely, $\phi x = 1 - x$, we can, by this article and the last, find particular solutions of the equation

$$\phi x = \left(\frac{c x^m}{1+x^n} \right)^p \phi x^2$$

$$1. \phi x = \frac{c^m}{2} \phi x^2 \quad \text{gives } \phi x = \left(\frac{c^m}{2} \right)^{-\frac{\lambda^2 x}{\lambda 2}} = (\lambda x)^{-\frac{\lambda c}{m \lambda 2} + 1}$$

$$2. \phi x = 2 x \phi x^2 \quad \dots \phi x = \frac{d}{dx} \left(\frac{\lambda^2 x}{\lambda 2} \right) = \frac{1}{\lambda 2 \cdot x \lambda x}$$

$$3. \phi x = c^m x \phi x^2 \quad \dots \phi x = \frac{(\lambda x)^{-\frac{1}{m} \frac{\lambda c}{\lambda 2}}}{\lambda 2 \cdot x}$$

$$4. \phi x = c x^m \phi x^2 \quad \dots \phi x = \frac{(\lambda x)^{-\frac{\lambda c}{2}}}{(\lambda 2)^m \cdot x^m}$$

$$5. \phi x = \frac{1}{1+x} \phi x^2 \quad \dots \phi x = 1 - x$$

$$6. \phi x = \frac{1}{1+x^n} \phi x^2 \quad \dots \phi x = 1 - x^n$$

$$7. \phi x = \left(\frac{c x^m}{1+x^n} \right) \phi x^2 \quad \dots \phi x = \frac{(\lambda x)^{-\frac{c}{\lambda 2}} (1-x^n)}{(\lambda 2)^m x^m}$$

$$8. \phi x = \left(\frac{c x^m}{1+x^n} \right)^p \phi x^2 \quad \dots \phi x = \frac{(\lambda x)^{-\frac{\lambda c}{2}} (1-x^n)^p}{(\lambda 2)^{mp} x^{mp}}.$$

(205.) The last is a particular case of the following. The solutions of

$$\phi x = \gamma \theta x \cdot \phi \alpha x$$

and

$$\phi x = \gamma x \phi \theta \alpha \theta^{-1} x$$

depend upon each other. If ϖx solve the first, $\varpi \theta^{-1} x$ solves the second: if ϖx solve the second, $\varpi \theta x$ solves the first. Hence a simple general expression of the problem may be given as follows. The solution of

Calculus of
Functions.

Calculus of Functions. $\phi x = \gamma x \phi \alpha x$ may be reduced to that of $\phi x = x \phi \gamma \alpha \gamma^{-1} x$, or the question is:—to express a given

function in the form $\phi^{-1} \left(\frac{\phi x}{x} \right)$. And it will be essential,

in future researches, to remark that the mode of solution of the equation does not depend on γx or αx , except in so far as they affect the form of $\gamma \alpha \gamma^{-1} x$. Given this last, the solution is given; or whatever γx may be, the method of finding the algebraical solution of

$$\phi x = \gamma x \phi \gamma^{-1} \kappa \gamma x$$

is independent of γx , or may be reduced to the solution of an equation not containing γx . For example, we find λx to be the value of ϕx in the equation

$$\phi x = \gamma x \phi (x^{\frac{1}{\gamma x}}).$$

(206.) When $\phi x = \gamma x \phi \alpha x$ can be solved, the solution of

$$\phi x = \beta x + \gamma x \phi \alpha x$$

can always be made to depend upon a form in which $\phi \alpha x$ has no coefficient except unity. For if νx be the solution of the former equation, we have

$$\frac{\phi x - \beta x}{\nu x} = \frac{\phi \alpha x}{\nu \alpha x}$$

or

$$\psi x = \frac{\phi x}{\nu x}, \quad \psi x = \frac{\beta x}{\nu x} + \psi \alpha x.$$

If a particular solution can be found to this, namely μx , then $\mu x \cdot \nu x$ is a particular solution of the preceding, and $\nu x (\mu x + \xi \alpha x)$ is the general solution. The corresponding equation of differences can evidently be solved by direct integration; being

$$\psi A^{-1} x = \frac{\beta A^{-1} x}{\nu A^{-1} x} + \psi A^{-1} (x - 1)$$

or

$$\Delta u_{x-1} = \frac{\beta A^{-1} x}{\nu A^{-1} x} \text{ a given function,}$$

where $u_x = \psi A^{-1} x$. And since the solution of

$$\phi x = \gamma x \phi \alpha x$$

also involves that of

$$\phi x = \lambda \gamma x + \phi \alpha x,$$

one general form of soluble equations is contained in the following conditions:

1. Let $\phi x = \gamma x \phi \alpha x$ be soluble by νx .
2. Let $\beta x = \nu x \lambda \gamma_1 x$, where $\phi x = \gamma_1 x \phi \alpha x$ is soluble.
3. Let the process of finite integration be granted, or the solution of $\Delta \psi x =$ a given function of x .

Thus we can solve

$$\phi x = (A'x)^m (n \lambda \alpha'x + c) + (\alpha'x)^m \phi \alpha x$$

as follows. A particular solution of the equation deprived of its known term is $\phi x = (A'x)^m$, and therefore we have to solve

$$\phi x = \lambda (\epsilon^x (\alpha'x)^m) + \phi \alpha x$$

or

$$\epsilon^{\phi x} = \epsilon^x (\alpha'x)^m \cdot \epsilon^{\phi \alpha x},$$

which gives

$$\epsilon^{\phi x} = \epsilon^{\epsilon \alpha x} \cdot (A'x)^m$$

or

$$\phi x = c A x + n \lambda A'x,$$

whence, in the original equation,

$$\phi x = (A'x)^m \{c A x + n \lambda A'x + \xi \alpha x\}.$$

VOL. II.

(207.) The two equations

$$\phi x = \beta x + \gamma x \phi \alpha x$$

$$\psi x = \beta_1 x + \gamma x \psi \alpha x$$

give the solution of

$$\chi x = m \beta x + m_1 \beta_1 x + \gamma x \chi \alpha x,$$

the sole condition between them being, that

$$\chi x - m \phi x - m_1 \psi x$$

must be a solution of

$$\phi x = (1 - m - m_1) \gamma x \phi \alpha x.$$

(208.) The instances in which we are able to solve this simple form of the functional equation of the first degree are of the most partial and isolated character. The instance $\phi x = x \phi (x - 1)$ gives a sufficient insight into the difficulty. Though the resolving function of this equation has long been used under the notation of Γx , it has never been expressed in any general form except as a definite integral. The well-known difficulties which attend the determination of that integral for all values of x are a sufficient indication of the transcendental which may be expected in the solution of the general equation.

(209.) If one of the functions $\beta x, \gamma x, \alpha x$, contain an arbitrary constant which it is required should itself be a particular value of the resolving function, a new condition is introduced which considerably limits the generality of the solution.* Let us suppose, for instance,

$$\phi x = \phi (x \phi a)$$

the solution of this equation, by preceding methods, is

$$\phi x = \theta \cos 2\pi \frac{\lambda x}{\lambda \phi a};$$

but θ is no longer indeterminate, since, upon making $x = a$, we have

$$\phi a = \theta \cos 2\pi \frac{\lambda a}{\lambda \phi a},$$

which condition θ must satisfy. At the same time, however, though the preceding stipulation limits the number of forms of the solutions yet obtained, we must remember (119.) that these solutions are, to all appearance, a very small proportion of those which might be found. And we also observe, that the appearance of another letter, with conditions as to the manner in which it must enter, entirely changes the class of problems to which the question must be referred. Since the solution of the preceding must be a function of x and a , let us represent it by $\phi(x, a)$, then what we have called ϕa means $\phi(a, a)$, in which a enters in a twofold manner; first, as it entered before, secondly, as x entered in the first. The substitution of $x \phi a$ for x is now that of $x \phi(a, a)$ for x , and the equation becomes

$$\phi(x, a) = \phi(x \phi(a, a), a),$$

in which a is to have a given value. But this condition can in no way affect the general question proposed in the problem, except so far as this: that though there may be a class of solutions which is true for the specific value of a only, and not for others, yet every solution of the general equation

$$\phi(x, y) = \phi(\tau \phi(y, y), y)$$

becomes a solution of the proposed equation, when y is made equal to a . Unless, therefore, we limit the pro-

* *Memoirs of the Analytical Society*, p. 107.

Calculus of
Functions.

blem at the beginning of this article, by adding, that the solutions presented are to be such as are true for one specific value of a only, we rather extend than limit the problem. But the preceding solution is not subject to any such limitation, the value of a being general.

To take a case of less difficulty, let us examine that given in the excellent Memoir already cited, namely,

$$\phi x^2 = \phi x + \phi a:$$

this we proceed to distinguish from the equation

$$\phi x^2 = \phi x + c.$$

The solution of the latter is

$$\phi x = c \frac{\lambda^2 x}{\lambda^2} + \xi x^2.$$

Assign any value whatever, $C \lambda^2$ to ϕa , and let ξx^2 be an arbitrary constant C' . Then if

$$C \lambda^2 = C \lambda^2 a + C',$$

or if

$$\phi x = C (\lambda^2 x - \lambda^2 a + \sqrt{2}),$$

the first equation is evidently satisfied. But this solution is as general as the corresponding solution of the second equation.

(210.) We had at first intended to exemplify at more length the method of Laplace, already described in (100.) But, on a closer examination, we find that the methods already given apply to every case in which such a reduction is useful with greater facility. Among the instances integrated by Laplace are*

$$(\phi x)^2 = \phi 2x + 2$$

$$\phi x^q = \phi m x + p.$$

With regard to the first, the equation

$$\phi x = c + c' (\phi \alpha x)^m$$

is easily solved with one particular solution, containing an arbitrary constant; and the independent artifice by which the equation of differences, corresponding to the first of the preceding, is integrated, is a step precisely corresponding to finding by observation the particular solution

$$\phi x = c^x + c^{-x}.$$

Of the second equation it is unnecessary to speak (103.) An equation solved by Monge, amounting to the following,

$$\phi (a u^m) - \phi (b u^m) = c u,$$

may be immediately reduced, by substituting x for $a u^m$, to the form

$$\phi x = p x^q + \phi (r x),$$

of which a particular solution may be immediately found by assuming $C x^m = \phi x$. And another equation in the same Memoir, of the form

$$\phi a x - \phi b x = p x^m - q x^n,$$

evidently admits of a particular solution of the form

$$C x^m - C' x^n + C'',$$

in which C and C' are determinate and C'' arbitrary

* We take these from the Memoir last cited, p. 111. It is necessary, however, that we should inform the reader (as otherwise he might, if he consulted that Memoir, dispute our assertion) that there is a material misprint in the equation cited from Monge. The two exponents n and m should be the same; the equation of Monge being of the form

$$\phi a u^m - \phi b u^m = c u,$$

not

$$\phi a u^m - \phi b u^n = c u.$$

See Monge's Memoir in the *Savans Etrangers*, 1773, p. 320.

(211.) We shall now proceed to some questions in Calculus of
Functions. which the Differential Calculus is combined with that of Functions.

In order to illustrate the distinction between the functional and differential symbols, let us propose the equations

$$\phi \left(\frac{dy}{dx} \right) = \phi y \quad \phi \alpha y = \phi y$$

for comparison. If ϕ be given, to find y or αy , then the first is a question of the inverse differential calculus, the second of inverse algebra. If y be a specific function of x in the first, and α a specific form in the second, then the two questions are of the same kind, since we can always express $\frac{dy}{dx}$ as a function of y , in any given case.

But if we leave y indeterminate, the first question can no more be solved than the second, when α is left indeterminate.

From the above we may, by a process precisely similar to those in (50.) and (102.), solve the first of these equations for a specific form of y , as follows. Express the n th differential coefficient of y as a function of n and y ; thus

$$D^n y = F(n, y),$$

in which a simultaneous substitution of $n-1$ for n , and $D y$ for y makes no change. Consider the first side as an arbitrary constant, and on this supposition determine (what we may by analogy call the differential inverse) the value of n . This value (δy) will be a function of y , which satisfies the equation

$$\phi \left(\frac{dy}{dx} \right) = \phi y - 1,$$

whence

$$\theta \cos 2\pi \delta y \text{ satisfies } \phi \left(\frac{dy}{dx} \right) = \phi y$$

$$c^{-\delta y} \text{ satisfies } \phi \left(\frac{dy}{dx} \right) = c \phi y,$$

$$\&c. \quad \&c. \quad \&c.$$

If y be called αx , and if we eliminate n between

$$D^n \alpha x = F(n, \alpha x) \text{ and } D^n \beta z = F_1(n, \beta z),$$

and then replace $D^n \alpha x$ and $D^n \beta z$ by arbitrary constants, or by any functions of $\cos 2\pi n$, we obtain a relation between βz and αx which is not altered by substituting $D \beta z$ and $D \alpha x$ for βz and αx , or if

$$\beta z = \phi(\alpha x) \quad D \beta z = \phi(D \alpha x).$$

But here we cannot, as in (50.), substitute for βz its value $\phi \alpha x$, and the remark in (18.) will show the reason.

For $D \beta z$ is not the same as $D \phi \alpha x$, the symbol D having a meaning dependent on the form of the functional symbol which follows it. Thus we find that

$$e^{bx} = (e^{ax})^{\frac{\lambda b}{\lambda a}}$$

is a relation between e^{bx} and e^{ax} , which is not altered by substituting $e^{bx} \cdot b$ for e^{bx} and $e^{ax} \cdot a$ for e^{ax} ; but the equation

$$D(e^{ax})^{\frac{\lambda b}{\lambda a}} = (D e^{ax})^{\frac{\lambda b}{\lambda a}}$$

is not true.

(212.) But we may make the preceding process verify a result we have before seen reason to anticipate, namely, that the transcendentals which satisfy $\phi \alpha x = \phi x$

Calculus of Functions. are of a much wider form than can be obtained from the most general use we have made of the function Ax .

It appears that we can solve $\phi\left(\frac{dy}{dx}\right) = \phi y$ by means of

the differential inverse of y , in the same manner as the preceding equation by the exponential inverse of αx . If then we assume

$$\frac{dy}{dx} = \alpha y,$$

and find the differential inverse of the resulting value of y expressed in terms of x , we obtain the following solution of $\phi\left(\frac{dy}{dx}\right) = \phi y$; namely, the expression $u_{\delta y}$,

where

$$u_{n+1} = \theta \cos 2\pi(n + u_n) \quad u_0 = \theta \cos 2\pi \delta y.$$

But this gives also a solution of $\phi \alpha y = \phi y$, and the least consideration will show that the two functions δy and Ay are of the most distinct characters: the first requiring only algebraical inversion, while the second requires the inversion of Γx , or of the solution of $\phi x = x\phi(x-1)$. If there be then one general expression which embraces every possible case of $\phi \alpha x = \phi x$, it must be one which indifferently contains all the solutions derived from the preceding, as well as from the equation in (119.)

But the preceding only serves to show how to deduce still more general notions of the possible extent of the solutions which $\phi \alpha x = \phi x$ may obtain. Let ∇y be a function derived from y , in any manner whatsoever, which will admit of successive derivations $\nabla^2 y$, $\nabla^3 y$, &c., subject to the condition

$$\nabla^m(\nabla^n y) = \nabla^{m+n}(y).$$

This includes ordinary functions, finite and infinitely small differences, as well as the more general sense in which this symbol ∇ has been used by Laplace. Indeed it is evident that any sense in which ∇ may be taken is an opening for a new and more general definition. Let

$$\nabla^n y = F(n, y),$$

an equation in which contemporaneous changes of n into $n-1$, and of y into ∇y does not affect the result. Putting an arbitrary constant for the first side, the value of n deduced from the preceding is an exponential inverse to ∇y , which satisfies the equation

$$\psi \nabla y = \psi y - 1,$$

and if

$$u_{n+1} = \theta \cdot \cos 2\pi(n + u_n) \quad u_0 = \theta \cos 2\pi \psi y,$$

then $u_{\psi y}$ is a solution of $\phi \nabla y = \phi y$.

In so many ways, therefore, as we can make $\nabla y = \alpha y$, in so many forms can the conditions of solution of $\phi \alpha y = \phi y$ be expressed.

The various problems in which the exponential inverse has been used have their obvious counterparts in cases

where $\frac{dy}{dx}$ is substituted for αy ; but the difficulties in

the way of expressing the most simple differential inverses will render the process useless for the present. The inversion of Γx , directly considered, amounts to the solution of the equation

$$\psi\left(\frac{x}{\psi x}\right) = \psi x - 1,$$

a very limited solution of which would be the solution

of $x = Ax \alpha x$, where Ax is the exponential inverse of αx . But this we have no means of solving. Merely as an expression of what sort of difficulty is in question we may write the equation $x = Ax \alpha x$ as follows,

$$\frac{\alpha x}{\alpha^2 x} = \frac{x}{\alpha x} - 1.$$

On this we will make one remark for students (and there are many such) who have acquired familiarity with the various artifices of analysis, without paying much attention to their connection. No process which any one method of solution requires was ever dispensed with in any other method. However different the various ways of solution of a question may appear to be, if method A were abandoned on account of a certain difficulty which did not explicitly appear in method B, then it is certain that the method B does contain within itself the direct way of overcoming the difficulty of method A. If, for instance, a problem of Mechanics may be shown to depend upon a certain integral which has not been found, and also upon a process of geometrical Algebra which presents no direct integration, and which solves the mechanical problem; then the method of Algebra must contain the method of finding the integral alluded to. Thus the question of finding x in terms of y in the equation

$$y = \int_0^\infty \alpha^{-x} x^a da$$

really contains that of finding a particular solution of

$$\alpha^{\frac{x}{\alpha^2 x}} = \alpha^{\frac{x}{\alpha^2 x} - 1} x,$$

where the functional exponents are themselves functions of x .

In the preceding, we do not speak of facility of solution, but only of possibility. And one method may be much more valuable than another as a method of suggestion of the artifices proper to be employed. For instance, the integration of equations of differences really contains the solution of all functional equations. But the employment of what we have called derivative functions frequently suggests a method of solution, in cases where the equation of differences would baffle all our efforts. But the solution of the functional equation once obtained, we find the equation of differences to be integrable, and also that greater power of penetration would have suggested an independent method for the latter.

(213.) But clearly to admit the assertion, that mathematical difficulties must always be conquered, and cannot be avoided or evaded, and that any successful artifice, which appears not to introduce the difficulty, does, in fact, introduce and surmount it, will require close consideration of the various cases which occur. It was immediately suggested to us by a friend, on our stating this principle to him, that the following was a case in point against us: an equation of n dimensions cannot be directly deprived of its n th term, or first power of x , without the solution of an equation of the $(n-1)$ th degree; whereas, by changing the roots into their reciprocals, the thing can be done by an equation of the first degree. But here, on further consideration, we see that we have, in fact, changed the problem, solved it as thus changed, and the whole question now lies in this: can the first problem be reduced to the second without supposing the solution of an equation of the $(n-1)$ th degree? The first problem is: given an equation with roots $a, a', \&c.$, to find another with roots $a+h, a'+h,$

Calculus of Functions &c., which shall be without the n th term. We find readily an equation whose roots are $\frac{1}{a} + k, \frac{1}{a'} + k, \&c.$,

which shall be without the second term. But what we want is h , and it will be found that we cannot determine h in terms of k without the solution of an equation of the $(n-1)$ th degree at least. If we know a , we can determine h from k ; but this supposes the solution of an equation of the n th degree: if we do not know a , we must solve an equation of the $n-1$ th degree.

(214.) The equation

$$\psi \frac{dy}{dx} = \frac{d}{dx} \psi y$$

is satisfied, without reference to the form of y , by

$$\psi y = a_0 y + a_1 \frac{dy}{dx} + a_2 \frac{d^2 y}{dx^2} + \&c.;$$

this belongs to a class of questions bearing no very perceptible analogy with those in (115.)

The same applies when ∇y is substituted for y , where ∇y is a linear function of successive values of y , when x increases by equal differences.

(215.) The equation

$$\psi \alpha x = \frac{d\psi x}{dx} \dots (1)$$

can be integrated whenever the following equation

$$\psi(x+h) - \psi x = h \psi \alpha x \dots (2)$$

can be solved. The following remark will illustrate the necessity of caution in applying conclusions drawn from one form to other forms. Equation (2) being solved with an arbitrary constant, the latter may be replaced by any function which does not change when x becomes either $x+h$, or αx . (We suppose αx independent of h .) It might seem, then, that h being diminished without limit in the solution of (2), which gives the solution of (1), the only condition for the arbitrary constant of (1) is, that it should not change when x is changed into αx . But this is certainly not true; for if ϖx satisfy (2), then $c\varpi x$ also satisfies it, but $\xi \alpha x \cdot \varpi x$ does not satisfy (1), unless $\xi \alpha x$ be constant. At the same time the following alternative may be easily proved. Either the function which does not change under x into $x+h$ and x into αx becomes a constant when $h=0$, or there is no such function.

(216.) The equation

$$\psi \alpha x = \frac{d^m \psi x}{dx^m}$$

has been reduced to a differential equation of the ordinary kind by Mr. Babbage, as follows. If for x we write $\alpha^p x$, we have

$$\psi \alpha^{p+1} x = \frac{d^m}{(d\alpha^p x)^m} \cdot \psi \alpha^p x,$$

where the second side denotes the performance of the following operation m times upon $\psi \alpha^p x$, namely, differentiation and division by $\frac{d\alpha^p x}{dx}$. Consequently, if the function αx be periodic of the n th order, we have, making $\psi x = \psi \alpha^n x = y$,

$$y = \frac{d^m}{(d\alpha^{n-1} x)^m} \cdot \frac{d^m}{(d\alpha^{n-2} x)^m} \dots \frac{d^m}{(dx)^m} \cdot y.$$

In the case where $m=1$ and $n=2$ we have for the solution of

$$\psi \alpha x = \frac{d\psi x}{dx}, \quad \alpha^2 x = x$$

$$y = \frac{d}{d\alpha x} \cdot \frac{dy}{dx}, \quad y = \psi x,$$

or

$$\frac{d^2 y}{dx^2} = \alpha' x \cdot y.$$

If $\alpha x = a - x$, this gives

$$y = c \cos x + c' \sin x = \psi x,$$

which satisfies the equation, when

$$c \cos a + c' \sin a = c'$$

$$c \sin a - c' \cos a = -c,$$

which two equations are the same in different forms.

(217.) Either the equation (1) preceding has an infinite number of solutions, or the equation

$$\phi \alpha x - \phi x = \frac{\varpi x}{\varpi \alpha x} \cdot \frac{d\phi x}{dx}$$

has no solution except $\phi x = \text{constant}$. For if ϖx be a particular solution of (1), then if there be another particular solution not of the form $c\varpi x$, let it be $\phi x \cdot \varpi x$. Then the preceding equation is the condition which determines ϕx . If the preceding have a particular solution $\varpi_1 x$, then a similar equation can be constructed which shall determine ϕx , so that $\phi x \varpi_1 x \varpi x$ is a particular solution. Proceeding in this way, and observing that the sum of two particular solutions of (1), or a particular solution multiplied by a constant, is also a particular solution, we have as a general solution of (1)

$$\psi x = c \cdot \varpi x + c_1 \varpi_1 x \varpi x + \dots,$$

whence follows the proposition stated.

(218.) The general expression for $\alpha^n x$ being

$$\Lambda^{-1}(\Lambda x - n),$$

we find the following differential equation,

$$\frac{d\alpha^n x}{dx} + \frac{d\Lambda x}{dx} \cdot \frac{d\alpha^n x}{dn} = 0,$$

consequently the equation

$$\frac{du}{dx} \cdot \frac{d^2 u}{dn^2} - \frac{du}{dn} \cdot \frac{d^2 u}{dx dn} = 0$$

contains among its solutions the n th functions of all functions of x whatsoever, and its integral may be written $\psi \phi^n x$, where ψ and ϕ are any forms whatsoever. Hence, by interchanging n and x , follows this theorem: that if $f(n, x)$ be such a function that its x th function with respect to n is the same as its n th function with respect to x , then $f(x, n)$ is one ordinate of a developable surface, where x and n are the other two.

We may also note that $\frac{d\alpha^n x}{dn}$ must be a function of $\alpha^n x$

only, or must be the solution of an equation of the form $\frac{du}{dn} = \phi u$.

(219.) Between the differential coefficients of $\alpha x, \alpha^2 x, \&c.$, where $\alpha^n x = x$, we find the following relations by differentiating both sides of the preceding equation with respect to x .

$$1 = \alpha' \alpha^{n-1} x \cdot \alpha' \alpha^{n-2} x \dots \alpha' \alpha x \cdot \alpha' x \dots (1)$$

where $\alpha' x$ means $\frac{d\alpha x}{dx}$, and consequently $\alpha' \alpha x$ means

$$\frac{d\alpha^2 x}{d\alpha x}. \quad \text{Hence } \alpha' x \text{ is a solution of the equation}$$

Calculus of
Functions.

$$\psi x \cdot \psi \alpha x \cdot \psi \alpha^2 x \dots \psi \alpha^{n-1} x = 1,$$

of which the general solution is $\psi x = e^{\theta x - \theta \alpha x}$, and by what has been proved (194.), the most general solution, exclusive of discontinuous functions or constants. And we have before found (201.) that $\alpha'x$ may be expressed in the preceding form.* Differentiating the logarithm of both sides of (1), we find

$$\frac{\alpha'x}{\alpha'x} dx + \frac{\alpha''\alpha x}{\alpha'\alpha x} d\alpha x + \dots + \frac{\alpha''\alpha^{n-1}x}{\alpha'\alpha^{n-1}x} d\alpha^{n-1}x = 0,$$

whence $\int \xi \alpha x \frac{\alpha''x}{\alpha'x} \cdot dx$ is a solution of the equation

$$\psi x + \psi \alpha x + \dots + \psi \alpha^{n-1} x = \text{constant} \dots (2),$$

or the preceding integral is a form of $C + \theta x - \theta \alpha x$. The integrals

$$\int \xi \alpha x \frac{\alpha''\alpha x}{\alpha'\alpha x} d\alpha x \quad \int \xi \alpha x \frac{\alpha''\alpha^2 x}{\alpha'\alpha^2 x} d\alpha^2 x, \text{ \&c.}$$

all possess the same property, and therefore the same form, though apparently very different, and considered as such when first given.†

(220.) The general solution of (2) in the last article has a particular case in which the function has been said to have the *complementary* property, but which might better be thus described. The mean of the successive values is always *one given value* of the function itself. Such a relation we see in

$$\alpha x = \frac{\pi}{2} - x \quad \alpha^2 x = x$$

$$\cos^2 x + \cos^2 \left(\frac{\pi}{2} - x \right) = 2 \cos^2 \frac{\pi}{4};$$

and in

$$\alpha x = \frac{1}{x} \quad \alpha^2 x = x$$

$$\tan^{-1} x + \tan^{-1} \frac{1}{x} = 2 \tan^{-1} 1.$$

If we assume

$$\psi x + \psi \alpha x + \dots + \psi \alpha^{n-1} x = n \psi k,$$

or $\psi x = \psi k + \theta x - \theta \alpha x$, we must determine k from the equation $\theta k - \theta \alpha k = 0$, one set of values of which corresponds to $k - \alpha k = 0$.

If the function αx be not periodic, the only solution of the preceding will be found to be

$$\psi x = \psi k + r^{-\Delta x} \xi \alpha x \quad r^n = 1.$$

(221.) A general method‡ has been given for reducing to a common differential equation

$$F \left(\begin{array}{cccc} \psi x, & \psi \alpha x, & \psi \alpha^2 x, & \dots & \psi \alpha^{n-1} x \\ \frac{d\psi x}{dx}, & \frac{d\psi \alpha x}{dx}, & \frac{d\psi \alpha^2 x}{dx}, & \dots & \frac{d\psi \alpha^{n-1} x}{dx} \end{array} \right) = 0;$$

but as it leads to very complicated details, we shall only here describe it generally.

In the preceding equation, substitute $\alpha x, \alpha^2 x, \dots, \alpha^{n-1} x$ instead of x , and for

* In the simple case of $\frac{1}{x}$, we have

$$\lambda^{-1} \left(\lambda \left(\frac{1}{x} \cdot \frac{1}{x} \right) - \lambda (\lambda x \cdot x) \right) = -\frac{1}{x^2}.$$

† Sir J. Herschël, *Edition of Spence*, p. 166.

‡ Babbage, *Philosophical Transactions*, 1816.

 Calculus of
Functions.

$\frac{d^n \psi \alpha^p x}{(d \alpha^p x)^n}$ write $\frac{d}{dx} \frac{1}{(\alpha^p)' x} \frac{d}{dx} \dots \psi \alpha^p x$ expanded.

We commence with $n(r+1)$ quantities

$$\begin{array}{cccc} \psi x & \psi' x & \psi'' x & \dots \psi^{(r)} x \\ \psi \alpha x & \psi' \alpha x & \psi'' \alpha x & \dots \psi^{(r)} \alpha x \\ \vdots & \vdots & \vdots & \vdots \\ \psi \alpha^{n-1} x & \psi' \alpha^{n-1} x & \psi'' \alpha^{n-1} x & \dots \psi^{(r)} \alpha^{n-1} x, \end{array}$$

of which all except the first line are to be eliminated; that is, $(n-1)(r+1)$ are to be eliminated. By successive substitutions we set out with n distinct equations; and every differentiation adds n to the number of equations, and only $n-1$ to the number of quantities to be eliminated, for those in the continuation of the first line of the above, namely,

$$\psi^{(r+1)} x \quad \psi^{(r+2)} x \dots$$

need not be eliminated. Consequently, after V differentiations, we have $n(1+V)$ equations with $(n-1)(r+1+V)$ quantities to be eliminated. If we make the first of these greater by 1 than the second, or

$$n(1+V) = (n-1)(r+1+V) + 1,$$

giving $V = (n-1)r$, we shall, after $(n-1)r$ differentiations, have one more equation than there are quantities to be eliminated. If, for instance, we take

$$\psi x + a \psi(1-x) = \frac{d\psi x}{dx} + b \frac{d\psi(1-x)}{dx}.$$

Here $n=2, r=1$, and one differentiation will be sufficient. The corresponding equation will be

$$\psi(1-x) + a \psi x = -\frac{d\psi(1-x)}{dx} - b \frac{d\psi x}{dx};$$

by differentiating these two equations, we obtain four equations between which to eliminate $\psi(1-x)$ and its first two differential coefficients. In this particular case we may easily see that the resulting equation will be linear, and of the second degree, that its solution will be of the form

$$C e^{mx} + C' e^{ux},$$

and finally, that $\psi x = 0$ is the only solution.

(222.) The preceding method will fail if the n equations of successive substitution are reducible to a smaller number, say to $n-p$. But it must be recollected, that we have as yet only *differentiated after substitution*, which will not, generally speaking, give the same result as if we *substituted after differentiation*. For instance,

if we take $\frac{1}{x}$, we find that

substitution and differentiation gives 1

differentiation and substitution gives $-x^2$.

If, then, we suppose that the first substitution gives $n-p$ independent equations, the number after substitution and V differentiations will be

$$n-p + (n-p)V.$$

Generally speaking, the dependence of the equations on each other will be destroyed in differentiation, so that from each of the V differential equations which arise from the primitive equation $n-1$ new equations can be produced by successive substitutions, or the total number will be

$$n-p + (n-p)V + (n-1)V;$$

this will be greater than

Calculus of
Functions. when

$$(n-1)(r+1+V)$$

$$1+V > \frac{n-1}{n-p}(r+1).$$

But cases may arise, in which, for any thing appearing to the contrary, both methods together will not produce more equations than new differential coefficients; and to these the method will not apply.

Again, the process may fail on account of a differential coefficient being introduced in one equation only, and in no other; that is, the number of differential equations specified in the formula may fail. In this case more differentiations must be made, and such equations must be chosen as will answer the purpose.

(223.) The above method is general in form, but any combinations of the equations which will eliminate all the results of successive operation is equally good. For instance, take the equation

$$\psi x \frac{d\psi x}{dx} = \psi \alpha x, \quad \alpha^2 x = x,$$

$$\text{substitution gives } \psi \alpha x \frac{d\psi \alpha x}{dx} = \alpha' x \psi x,$$

$$\text{multiplication gives } \frac{d\psi x}{dx} \cdot \frac{d\psi \alpha x}{dx} = \alpha' x.$$

Differentiate the first, and substitute from the third, which gives, making $y = \psi x$,

$$\left(\frac{dy}{dx}\right)^2 + y \frac{dy}{dx} \frac{d^2 y}{dx^2} = \alpha' x.$$

If $\alpha x = 1 - x$, a particular solution of the preceding is $y = C - x$, and it will be found that $\frac{1}{2} - x$ satisfies the conditions.

The preceding equation belongs to a class no general method of integrating which has been found. We here see a great distinction between the case in which $\alpha^2 x = x$ and all others. In the first, $\frac{dy}{dx}$ is a function which, for

certain values of the constants, is of the form $\frac{\psi x}{\psi \alpha x}$,

that is, satisfies the equation $\chi x \chi \alpha x = 1$. This leads us to the following observation. It cannot have escaped the notice of any one who has looked at the history of the Differential Calculus, how soon, after attention was first turned to the subject in a general point of view, the great forms of differential equations which are now integrable were discovered; and how little progress has been made during the present century. We do not speak of particular equations, involving no general functional symbol, but of those in which some form is left indeterminate. The preceding equation adds some additional force to the presumption, that the reason why no more general forms are discovered lies in the incapability of analysis, as it stands at present, to express the primitive functions of such equations. For it draws a remarkable distinction between the case of $\alpha^2 x = x$ and all others. We need not allude to the equation known by the name of Riccati, and to others, in which the ordinary processes of analysis succeed only with very limited cases.

It is true that infinite series may be made to express many otherwise unattainable results, but these themselves are open to the same difficulties. When their envelopes are not reducible either to the integration of a

differential equation, or the solution of a functional equation, they are, analytically considered, quantities of an entirely unknown form. Generally speaking, either a differential or functional equation may be chosen, but as this may not appear with regard to many series, we shall show in the following article one method of proceeding.

(224.) Suppose we wish to reduce the series

$$a - \frac{a^2}{2 \cdot 3} + \frac{a^3}{2 \cdot 3 \cdot 4 \cdot 5} - \&c.$$

to a particular case of the solution of a functional equation. In the denominators, instead of 1, 2, &c. write $x+1$, $x+2$, &c. Call the result ψx , which gives

$$\begin{aligned} \psi x &= \frac{a}{x+1} - \frac{a^2}{(x+1)(x+2)(x+3)} + \&c. \\ &= \frac{a}{x+1} - \frac{a^2}{(x+1)(x+2)} \psi(x+2). \end{aligned}$$

The general solution of which, if it could be found, would give $\psi(0) = \sin a$. By a process of this kind Legendre* reduced the series for the tangent of x to a continued fraction, which he employed to demonstrate the incommensurability of the circle and its diameter.

(225.) We cannot quit the subject of the connection of the functional and differential calculus without saying something on the very remarkable theorem of Fourier,† by which one value of a function is expressed in terms of a definite integral which contains the general value. If we write the two series

$$F x = A_1 \cos x + A_2 \cos 2x + A_3 \cos 3x + \dots$$

$$f x = a_1 \sin x + a_2 \sin 2x + a_3 \sin 3x + \dots$$

we see in them the conditions

$$F(x) = F(-x) \quad f(x) = -f(-x)$$

by the known properties of the sine and cosine. Hence an attempt to represent a function of the form $F x$ by a series of sines, or $f x$ by a series of cosines, must introduce some symbol of impossibility, or at least of discontinuity. And the same may be said of the series

$$F x = Q_1 \cos q_1 x + Q_2 \cos q_2 x + \dots$$

$$f x = P_1 \sin p_1 x + P_2 \sin p_2 x + \dots$$

where $Q_1 \dots P_1 \dots q_1 \dots p_1 \dots$ are not functions of x .

The integral $\int \phi x dx$, between the limits $x = a$ and $x = b$, may be conceived to be the limit of the following process. Divide the interval $b - a$ into n parts, each equal to k . Then the sum of the several terms $\phi a \cdot k + \phi(a+k) \times k + \phi(a+2k) \times k + \dots + \phi(a+nk) \times k$ is an expression, the limit of which, made by increasing n or diminishing k without limit, is the definite integral in question.

If, then, in the preceding series, we assume

$$q_1 = k \quad q_2 = 2k \dots q_n = nk,$$

and suppose $Q_1, Q_2, Q_3 \dots$ to be the corresponding values of a certain function of q or mk , each multiplied by k , namely,

$$Q_1 = k \psi k \quad Q_2 = k \psi 2k \dots Q_n = k \psi nk,$$

and if we then suppose k to diminish without limit, we have

$$F x = \int_0^x \psi q \cdot \cos qx \cdot dq,$$

in which $F x$ now represents the limit of the series.

* See notes to Sir D. Brewster's translation of his *Geometry*.

† *Théorie de la Chaleur*, p. 449.

Calculus of Functions. But let the expanded equation, as it stands, be multiplied by $\cos mkx \times dx$, and then integrated with respect to x , from $kx = 0$ to $kx = \pi$. By the common processes of the integral calculus, we know that (m and r being whole numbers)

$$\int_0^\pi \cos mkx \cdot \cos rkx \, dx = 0 \text{ or } \frac{1}{2} \frac{\pi}{k}$$

the first when m and r are different, the second when they are the same. Hence it follows, that the preceding integration destroys every term, except only that in which $\cos mx$ is found, which it reduces to

$$k \psi mk \times \frac{\pi}{2k} \text{ or } \frac{\pi}{2} \psi mk.$$

Let k diminish without limit, and let m at the same time increase without limit, in such a way that mk is always equal to the general value q ; then the superior

limit of x in the integration, which is $\frac{\pi}{k}$, (for kx then $= \pi$), increases without limit, and the result is, that

$$\frac{\pi}{2} \psi q = \int_0^\infty Fx \cdot \cos qx \cdot dx$$

if

$$Fx = \int_0^\infty \psi q \cos qx \cdot dq.$$

Exactly in the same way, using the sines instead of cosines, and remembering that

$$\int_0^\pi \sin mkx \cdot \sin rkx \cdot dx = 0 \text{ or } \frac{1}{2} \frac{\pi}{k},$$

according as m and r are different or equal, we deduce that

$$\frac{\pi}{2} \chi p = \int_0^\infty fx \cdot \sin px \cdot dx$$

if

$$fx = \int_0^\infty \chi q \sin px \, dp.$$

From which it appears that $\left(\frac{\pi}{2}\right)^{\frac{1}{2}} \psi q$ and Fx , when ψq and Fx satisfy either equation, have this property, that an interchange of x and q is accompanied by an interchange of F and ψ ; and also, that $\left(\frac{\pi}{2}\right)^{\frac{1}{2}} \chi p$ and fx have the same property. M. Cauchy* has proposed to call these pairs *reciprocal functions* of the first and second kind; but the name reciprocal has been given to other functions, and is besides too valuable as a general term to be thus appropriated. We should propose to call them *Fourier's reciprocals*, after their discoverer.

(226.) Substitution in the second equation of each set gives the following theorems:

$$Fx = \frac{2}{\pi} \int_0^\infty \cos qx \, dq \int_0^\infty Fx \cdot \cos qx \cdot dx$$

$$fx = \frac{2}{\pi} \int_0^\infty \sin px \, dp \int_0^\infty fx \cdot \sin px \, dx;$$

and in the first integration we may write v for x , the general symbol of the variable being indifferent in a definite integral: we may also make $q = p$, since the limits of the two are the same; and we then have, observing that we have now a separation of variables in the successive integrations,

$$Fx = \frac{2}{\pi} \int_0^\infty \int_0^\infty Fv \cdot \cos qv \cdot \cos qx \, dq \, dv$$

$$fx = \frac{2}{\pi} \int_0^\infty \int_0^\infty fv \sin qv \sin qx \, dq \, dv.$$

If the integration with respect to v be taken from $-\infty$ to $+\infty$, then each integral is merely doubled; for since

$$Fv = F(-v) \text{ and } \cos qv = \cos(-qv),$$

we have

$$Fv \cdot \cos qv = F(-v) \cos(-qv).$$

Similarly, since

$$fv = -f(-v) \text{ and } \sin qv = -\sin(-qv),$$

we have also

$$fv \sin qv = f(-v) \sin(-qv),$$

whence the proposition stated. But for a contrary reason, namely, because

$$Fv \sin qv = -F(-v) \sin(-qv)$$

$$fv \cdot \cos qv = -f(-v) \cos(-qv),$$

we have

$$\int_{-\infty}^\infty Fv \cdot \sin qv \, dv = 0 \quad \int_{-\infty}^\infty fv \cdot \cos qv \, dv = 0;$$

consequently,

$$\int_{-\infty}^\infty (Fv + fv) \sin qv \, dv = \int_{-\infty}^\infty fv \sin qv \, dv$$

$$\int_{-\infty}^\infty (Fv + fv) \cos qv \, dv = \int_{-\infty}^\infty Fv \cos qv \, dv.$$

Substituting these in the preceding results, taking the first integration from $-\infty$ to $+\infty$, and writing

$$\frac{1}{2} \int_{-\infty}^\infty \text{ instead of } \int_0^\infty,$$

we find

$$Fx = \frac{1}{\pi} \int_0^\infty \int_{-\infty}^\infty (Fv + fv) \cos qv \cos qx \, dq \, dv$$

$$fx = \frac{1}{\pi} \int_0^\infty \int_{-\infty}^\infty (Fv + fv) \sin qv \sin qx \, dq \, dv;$$

whence, by addition,

$$Fx + fx = \frac{1}{\pi} \int_0^\infty \int_{-\infty}^\infty (Fv + fv) \cos q(x - v) \, dq \, dv.$$

(227.) Any function whatsoever may be reduced to the form $Fx + fx$, supposing constants and zero to be included in these forms Fx and fx . For any function ϕx may be written

$$\phi x = \frac{\phi x + \phi(-x)}{2} + \frac{\phi x - \phi(-x)}{2},$$

the first term of which falls under Fx , and the second under fx .

Consequently, we have this general theorem, which we may write in two different ways. If ϕx be any function of x whatsoever,

$$\phi x = \int_0^\infty \int_{-\infty}^\infty \phi v \cos q(x - v) \, dq \, dv$$

$$= \int_{-\infty}^\infty \phi v \, dv \int_0^\infty \cos q(x - v) \, dq;$$

between which, however, there is a distinction of some importance to be drawn. In the case of $\iint P Q \, dx \, dy$, where P and Q are functions of x only and of y only, and the limits are definite and independent of x and y , it is absolutely indifferent whether we proceed in the order denoted by $\int P \, dx \int Q \, dy$, or in that of $\int Q \, dy \int P \, dx$. The same thing may be said as to definite and independent limits of the general form $\iint \psi x \phi(x, y) \, dx \, dy$. But where we have to integrate such a function as the preceding, and when the integration with respect to y ,

* Exercices de Mathématiques, vol. ii, p. 141.

Calculus of Functions. owing to the particular values of the limits, causes any limitation of form, such as the loss of terms which appear when the limits are general, &c., it is obvious that the subsequent integration with respect to x will be altered in form: in fact, the operation is not performed on the same function as when the limits are kept general.* This order, then, is *absolutely necessary* when the deduction of the integral produced it; and *absolutely false* when the deduction of the integral produced the other. The order is a necessary condition of the result. If, for instance, the result of an investigation be

$$\int y^x dx dy, \text{ from } y = 1 \text{ to } y = a, \\ \text{from } x = -\infty \text{ to } x = -1.$$

According as we integrate, first with respect to x , or to y , we have the results

$$\int_1^a \frac{dy}{y \log y} \text{ or } \int_{-\infty}^{-1} \frac{a^{x+1} - 1}{x+1} dx,$$

which are not the same.

The preceding theorem of Fourier was deduced upon the supposition of the first integration being with respect to v . It remains to see what will be the consequence of supposing it to be with respect to q . Generally, we have ($c = x - v$)

$$\int \cos cq \cdot dq = \frac{\sin cq}{c} + \text{constant},$$

which we cannot attempt to integrate within the required limits, because the cosine of ∞ (an undefined constant) enters. Also the expression of

$$\int_0^\infty \cos cx dx = \int_0^\pi \cos cx \cdot dx + \int_\pi^{2\pi} \cos cx dx + \dots$$

gives the result zero; as does every other similar method. This result not making the theorem true, we must either integrate between general limits, and make these limits infinite when the final result has been obtained, or keep to the order of the investigation.

(228.) By the first of the two methods M. Defflers has established the theorem synthetically.† Taking $\int \cos q(x-v) dq$ from $q=0$, to an undetermined limit, we have

$$\int_0^\infty \cos q(x-v) dq = \frac{\sin q(x-v)}{x-v} \\ \phi x = \frac{1}{\pi} \int_{-\infty}^\infty \frac{\sin q(x-v)}{x-v} \phi v dv,$$

in the result of which q is to be made infinite. Assume

$$v = x + \frac{z}{q}, \text{ which gives}$$

$$\phi x = \frac{1}{\pi} \int_{-\infty}^\infty \frac{\sin z}{z} \phi \left(x + \frac{z}{q} \right) dz:$$

expand the function of the binomial, which gives

$$\phi x = \frac{1}{\pi} \int_{-\infty}^\infty \phi x \frac{\sin z}{z} dz,$$

the other terms vanishing when q is made infinite, unless $\int_{-\infty}^\infty \sin z z^m dz$ be infinite for finite values of m , which

* A general value of a constant is one which does not produce any reduction in the result. Integrate $2x+a$ from $x=0$ to $x=c$, and we have c^2+ac , which is general; the general form can be restored from it. Integrate from $x=0$ to $x=a$, and we have $2a^2$, from which the general form cannot be recovered.

† Formerly a pupil of the *Ecole Normale*, and deceased some years ago. This demonstration is given by M. Poisson, *Théorie de la Chaleur*, p. 209.

is not the case. The preceding equation is true, for it is known that $\int_{-\infty}^\infty \frac{\sin z}{z} dz = \pi$ Calculus of Functions.

(229.) The very singular nature of Fourier's theorem, and its not having appeared in English, to the best of our knowledge, in any work yet published, must be our excuse for presenting yet one more demonstration, given by M. Poisson,* and which contains several analytical considerations worthy of attentive study. We know that so long as a constant is perfectly general in value, it is indifferent whether it is made to vanish before or after integration; consequently, Fourier's theorem may be presented in the following form:

$$\phi x = \frac{1}{\pi} \int_0^\infty \int_{-\infty}^\infty \phi v \cos q(x-v) e^{-kq} dq dv,$$

provided that in the result $k=0$. And that this theorem is true may be thus proved. If we integrate the following by parts in the usual way, we find

$$\int_0^\infty \cos q(x-v) e^{-kq} dq = \frac{k}{k^2 + (x-v)^2},$$

whence

$$\phi x = \frac{1}{\pi} \int_{-\infty}^\infty \frac{k \phi v dv}{k^2 + (x-v)^2} \dots (A)$$

Let the reader remark that the indefinite character of the first integration has now disappeared, or rather is deferred to the end of the process, when it will be reduced to making $k=0$. We now give a literal translation of the process of M. Poisson, to which we shall add one which is more accessible to the common reader. It is also to be observed that the former process applies only to those functions in which ϕv is not infinite for any value of v , while the latter is general.

"Now, ϕv never becoming infinite, it is evident that this simple integral (A) will be infinitely small at the same time as k , except for the extent, in which the values of v differ infinitely little from those of x ; it will suffice, then, to integrate from $v=x-u$ to $v=x+u$, u being a positive and infinitely small quantity; between these limits ϕv may be considered constant, and equal to ϕx ; in consequence we have

$$\int_{-\infty}^\infty \frac{k \phi v dv}{k^2 + (x-v)^2} = \phi x \int_{-\infty}^\infty \frac{k dv}{k^2 + (x-v)^2} = \phi x \tan^{-1} \frac{v-x}{k}$$

which integral, between the assigned limits, is

$$2 \phi x \tan^{-1} \frac{u}{k},$$

which is $\pi \phi x$ when $k=0$."

Or we may proceed as follows. In the left-hand side of (A) write $x+h$ for v ; we have then $dh=dv$, and expanding $\phi(x+h)$ by Taylor's theorem, we have, for the integral required,

$$\frac{1}{\pi} \left(\phi x \int \frac{k dh}{k^2 + h^2} + \sum \frac{d^n \phi x}{d x^n} \frac{1}{2 \cdot 3 \dots n} \int \frac{k h^n dh}{k^2 + h^2} \right).$$

If, now, we consider separately (n being a whole number)

$$k \int \frac{h^{2n+1} dh}{k^2 + h^2} \text{ and } k \int \frac{h^{2n} dh}{k^2 + h^2},$$

we see from the form of the first that it vanishes when taken between $h=-\infty$ and $h=\infty$, which correspond

* In a Memoir entitled *Sur la Théorie des Ondes*, in the Memoirs of the Institute, Année 1816.

Calculus of Functions. $v = -\infty$ and $v = +\infty$. Now the second, by algebraical reduction, may be brought to the form

$$k \int (h^{2n-2} + Ah^{2n-4} + \dots + G) dh + k^{2n+1} \int \frac{dh}{k^2 + h^2}.$$

All the independent terms of which disappear, even independently of k , when integrated between the given limits; and the last term, being generally

$$k^{2n} \tan^{-1} \frac{h}{k}, \text{ or, between the limits, } \pi k^{2n},$$

vanishes when $k = 0$. We have, therefore, only to consider

$$\frac{1}{\pi} \phi x \int \frac{k dh}{h^2 + k^2}, \text{ or } \frac{\phi x}{\pi} \tan^{-1} \frac{h}{k} \text{ (from } h = -\infty \text{ to } h = +\infty),$$

which is ϕx , the same as before.

(230.) We shall now take some miscellaneous examples of simple functional equations. Some of them are from Mr. Babbage's collection of examples in the supplementary volume to the Cambridge translation of Lacroix.

$$\text{Let } \beta x = \frac{\psi x + \psi \alpha x}{1 - \psi x \cdot \psi \alpha x}.$$

Assume

$$\psi x = \tan \phi x,$$

which gives

$$\beta x = \tan(\phi x + \phi \alpha x) \text{ or } \phi x + \phi \alpha x = \tan^{-1} \beta x.$$

If ωx be a particular solution of the last, the general solution of the first is

$$\tan(\omega x + \theta \cos \pi A x) \text{ if } \theta(-x) = -\theta x.$$

If $\alpha^2 x = x$, the first equation is incongruous, unless βx be a symmetrical function of x and αx , in which case a solution of the third equation is

$$\frac{\theta x}{\theta x + \theta \alpha x} \tan^{-1} \beta x,$$

whence

$$\psi x = \tan\left(\frac{\theta x}{\theta x + \theta \alpha x} \tan^{-1} \beta x\right),$$

or

$$\psi x = \frac{1}{\sqrt{-1}} \frac{(1 + \sqrt{-1} \beta x)^{\theta_1 x} - (1 - \sqrt{-1} \beta x)^{\theta_1 x}}{(1 + \sqrt{-1} \beta x)^{\theta_1 x} + (1 - \sqrt{-1} \beta x)^{\theta_1 x}}$$

where

$$\theta_1 x = \frac{\theta x}{\theta x + \theta \alpha x}.$$

The preceding is an instance suggested by the formulæ of Trigonometry; but if for βx we write $\sqrt{-1} \beta x$, and $\sqrt{-1} \psi x$ for ψx , we have for the solution of

$$\begin{aligned} \beta x &= \frac{\psi x + \psi \alpha x}{1 + \psi x \cdot \psi \alpha x} \\ \psi x &= \frac{(1 + \beta x)^{\theta_1 x} - (1 - \beta x)^{\theta_1 x}}{(1 + \beta x)^{\theta_1 x} + (1 - \beta x)^{\theta_1 x}} \\ &= \frac{1}{\sqrt{-1}} \tan(\theta_1 x \tan^{-1}(\sqrt{-1} \beta x)). \end{aligned}$$

(231.) Let

$$\psi x + \psi \alpha x = 0 \quad \alpha^2 x = 0.$$

The method given by Mr. Babbage for the determination of the form of ψ is as follows. Solve the equation

$$\psi x + c \psi \alpha x = c' \beta x,$$

giving

VOL. II.

or

$$\psi \alpha x + c \psi x = c' \beta \alpha x,$$

$$\psi x = \frac{c'}{1 - c^2} (\beta x - c \beta \alpha x).$$

Now suppose c' a function of c , which vanishes when $c = 1$, which may be satisfied so as to make the value of $\frac{c'}{1 - c^2}$ any whatever: let it be C . Hence

$$\psi x = C (\beta x - \beta \alpha x) = \xi \alpha x (\beta x - \beta \alpha x).$$

It might here appear as if there were two arbitrary functions ξ and β ; but this is not in reality the case since $\beta x - \beta \alpha x$ is itself of the form

$$(x - \alpha x) \xi \alpha x \text{ because } \frac{\beta x - \beta \alpha x}{x - \alpha x}$$

is unchanged by writing αx for x , that is, by interchanging x and αx .

(232.) Further to illustrate this appearance of more arbitrary functions than one, in a case where it has been proved that such a thing cannot be, let us take

$$\psi x + \psi \alpha x = \beta x \quad \alpha^2 x = x.$$

Now βx must itself be a case of $\xi \alpha x$, and we find

$$\psi x = \frac{\theta x}{\theta x + \theta \alpha x} \beta x + \xi \alpha x (x - \alpha x),$$

using the reduced form of the last solution. But

$$\frac{\theta x}{\theta x + \theta \alpha x} = \frac{1}{2} + \frac{1}{2} \cdot \frac{\theta x - \theta \alpha x}{\theta x + \theta \alpha x},$$

the second term of which (as well before as after multiplication by βx) is a form of $\xi \alpha x (x - \alpha x)$, whence

$$\psi x = \frac{\beta x}{2} + \xi \alpha x (x - \alpha x)$$

is really as general as any other solution.

The solution of

$$\psi x + \psi \alpha x + \psi \alpha^2 x = 0 \quad \alpha^3 x = x$$

is

$$\psi x = \left(\frac{\theta x}{\theta x + \theta \alpha x + \theta \alpha^2 x} - \frac{1}{3} \right) \xi \alpha x,$$

which is the same general form as

$$(2\theta x - \theta \alpha x - \theta \alpha^2 x) \xi \alpha x,$$

and appears to have two arbitrary functions, and not more. For if we add two such forms as the preceding together, which is a solution apparently containing four arbitrary functions, it amounts to no more than writing

$$\theta x + \theta_1 x \frac{\xi_1 \alpha x}{\xi \alpha x} \text{ instead of } \theta x$$

in the preceding; that is, changing the form of an arbitrary function, by making it a function of other arbitrary functions. And the same may be proved of

$$(a \cdot \theta x + a_1 \theta \alpha x + \dots + a_{n-1} \theta \alpha^{n-1} x) \xi \alpha x \quad (\alpha^n x = x).$$

But these two arbitrary functions are only one in reality; for if we write the preceding under the form

$$(\theta x - \theta \alpha^2 x) \xi \alpha x - (\theta \alpha x - \theta x) \xi \alpha x,$$

we see a form of $\gamma x - \gamma \alpha x$.

To this form every solution of the equation

$$\psi x + \psi \alpha x + \dots + \psi \alpha^{n-1} x = 0 \quad \alpha^n x = x$$

may be reduced. A particular solution of the equation is

Calculus of
Functions.

$C\theta x + C'\theta\alpha x + \dots + C^{(n-1)}\theta\alpha^{n-1}x$,
where $C, C', \&c.$ are forms of $\xi\alpha x$, and

$$C + C' + \dots + C^{(n-1)} = 0.$$

The application of the condition last named gives

$$C(\theta x - \theta\alpha^{n-1}x) + C_1(\theta\alpha x - \theta\alpha^{n-1}x) + \dots;$$

each term of which is of the form $\gamma x - \gamma\alpha x$; for if we denote $\theta\alpha^m x$ by P_m , we find that

$$P_m - P_{m+1} = P_m + P_{m+1} + \dots + P_{m+n-1} \left\{ \begin{array}{l} \gamma x \\ - (P_{m+1} + P_{m+2} + \dots + P_{m+n}) \end{array} \right\} \text{ or } \left\{ \begin{array}{l} \gamma x \\ - \gamma\alpha x. \end{array} \right.$$

Hence it follows that the general solution of

$$\psi x + \psi\alpha x + \dots + \psi\alpha^{n-1}x = \beta x \quad (\alpha^n x = x)$$

is

$$\psi x = \frac{\beta x}{n} + \theta x - \theta\alpha x,$$

and βx must be a form of $\xi\alpha x$, or when this is not the case, the solutions are all discontinuous.

(233.) The equation $\psi x = b + c\psi\alpha x$, $\alpha^n x = x$ gives $\psi x = \frac{b}{1-c}$ for the only continuous solution; but

taking this as a particular solution, we find the general solution to be

$$\psi x = \frac{b}{1-c} + c^{\Lambda x} \xi\alpha x;$$

where, however, Λx is discontinuous in value. In a similar way, we find for the solution of

$$\begin{aligned} \psi\alpha &= \beta x + \gamma x\psi\alpha x \quad (\alpha^n x = x) \\ \psi x &= \mu x + \nu x\xi\alpha x, \end{aligned}$$

where μx is to be obtained from (192.), and νx is a discontinuous solution of $\psi x = \gamma x\psi\alpha x$. It appears in this way that the equation has in all cases an arbitrary function; but that where only a single solution is found, as in (192.), the arbitrary function has a coefficient of discontinuous value, while the appearance of the result in the indeterminate form considered in (197.) is the sign of the conditions being satisfied, under which a continuous arbitrary function is possible.

(234.) When one or more of the terms is missing in the equation

$$\psi x + \psi\alpha x + \dots = 0 \quad \alpha^n x = x$$

there is no continuous solution, except $\psi x = 0$. For suppose, for instance, that $\psi\alpha^m x = P_m$, and that

$$P_{m_1} + P_{m_2} + \dots = 0,$$

where $m_1, m_2, \&c.$ do not contain the complete series from 0 to $n-1$, both inclusive. Let ΣP denote this complete series; then, by successive substitution of αx for x , and addition, the equation

$$\Sigma P + \Sigma P + \dots = 0$$

is obtained, or the solutions of the first, if any, must be solutions of $\Sigma P = 0$, that is, must be of the form $\phi x - \phi\alpha x$, from which we find, by means of the first equation, that

$$\phi_{m_1} + \phi_{m_2} + \dots = \phi_{m_1+1} + \phi_{m_2+1} + \&c.,$$

or each side is a symmetrical function of $x, \alpha x, \dots$ up to $\alpha^{n-1}x$. This cannot be the case, unless each term be such. Suppose, for instance, that $(\alpha^2 x = x)$, the following incomplete sum is a form of $\xi\alpha x$:

$$\phi x + \phi\alpha x + \phi\alpha^2 x + \phi\alpha^3 x.$$

Then, since the remainder of the complete sum is the

same, and since successive substitution does not alter this property, we find that each of the following is a form of $\xi\alpha x$, Calculus of
Functions.

$$\begin{aligned} & (P_2 + P_3 + P_4) (P_0 + P_1 + P_2) (P_2 + P_4 + P_5 + P_6) \\ & (P_0 + P_2 + P_3 + P_4) (P_1 + P_3 + P_5) (P_0 + P_4 + P_5) \&c., \end{aligned}$$

whence the sum of any four, or of any three, is a form of $\xi\alpha x$, whence the difference of any two is the same. Hence

$$P_0 - P_1 = P_1 - P_2 \dots = P_{n-1} - P_0,$$

but $\Sigma (P_0 - P_1) = 0$; therefore $P_0 - P_1 = 0$ or P_0 is itself a form of $\xi\alpha x$, and $P_0 - P_1$, the solution of the given equation, is $= 0$.

The same thing might be proved by observing, that the particular solution, derived as before,

$$C P_0 + C' P_1 + \dots,$$

when the series is incomplete, does not give one equation of condition $\Sigma C = 0$, but $n-1$ partial sums, severally equal to nothing, from which follows $C = 0$, $C' = 0$, &c.

In a similar manner it may be shown, that the equation

$$\pm \psi x \pm \psi\alpha x \pm \dots = 0$$

is impossible when any of the terms differ in sign. For in that case, one substitution and addition will either destroy or double any given term, and the last case results.

We must except from the preceding the case where the number of negative and positive terms are equal, in which case the general solution is evidently $\xi\alpha x$; and, secondly, the case in which the terms are alternately positive and negative, in which substitution reproduces the equation. In the latter case, we have either an even number of terms, as in the case of

$$P_0 - P_1 + P_2 - P_3 = 0 \quad \alpha^4 x = x,$$

equivalent to $Q_0 + Q_2 = 0$, or $Q_0 = 0$, or $P_0 = P_1$, that is, to $P_0 = \xi\alpha x$: or we have an odd number of terms, as in

$$P_0 - P_1 + P_2 - P_3 + P_4 = 0 \quad \alpha^5 x = x,$$

in which successive substitution and addition gives

$$P_0 + P_1 + P_2 + P_3 + P_4 = 0,$$

whence

$$P_0 + P_2 + P_4 = 0 \quad P_0 = 0.$$

(235.) The general solution of the equation

$$a_0 P_0 + b_0 P_1 + c_0 P_2 + \dots + k_0 P_{n-1} = l_0,$$

where P_1 is the same function of αx which P_0 is of x , and where $\alpha^n x = x$, offers no other difficulty except the very complicated character of the terms which must be employed. But it may be easily reduced in the case when $n = 3$, to the one already solved in (197.), by assuming $P_0 = Q_0 + v_0 Q_1$; and the following is the general process for reducing the preceding equation to the form

$$m_0 Q_0 + n_0 Q_1 = l_0.$$

Assume

$$P_0 = Q_0 + b_0 Q_1 + c_0 Q_2 + \dots + i_0 Q_{n-2}$$

$$P_1 = Q_1 + b_1 Q_2 + c_1 Q_3 + \dots + i_1 Q_{n-1}$$

$$P_2 = Q_2 + b_2 Q_3 + c_2 Q_4 + \dots + i_2 Q_0$$

$$\dots \dots \dots \dots \dots \dots \dots \dots \dots \dots \dots \dots \dots$$

$$P_{n-1} = Q_{n-1} + b_{n-1} Q_0 + c_{n-1} Q_1 + \dots + i_{n-1} Q_{n-2}$$

Determine the $n-2$ quantities $b_0, c_0, \dots, i_0$ by following equations:

Calculus of Functions.

$$\begin{aligned} b_0 i_1 + c_0 h_2 + e_0 g_3 + \dots + i_0 b_{n-2} + k_0 &= 0 \\ a_0 i_0 + b_0 h_1 + c_0 g_2 + \dots + g_0 b_{n-3} + i_0 &= 0 \\ k_0 i_{n-1} + a_0 h_0 + b_0 g_1 + \dots + f_0 b_{n-4} + g_0 &= 0 \\ \dots &\dots \end{aligned}$$

and so on until there are $n - 2$ equations. For a particular instance, suppose $n = 5$, and that

$$a_0 P_0 + b_0 P_1 + c_0 P_2 + e_0 P_3 + f_0 P_4 = l_0.$$

Assume

$$P_0 = Q_0 + b_0 Q_1 + c_0 Q_2 + e_0 Q_3,$$

and

$$\begin{aligned} b_0 e_1 + c_0 c_2 + e_0 b_3 + f_0 &= 0 \\ a_0 e_0 + b_0 c_1 + c_0 b_2 + e_0 &= 0 \\ f_0 e_4 + a_0 c_0 + b_0 b_1 + c_0 &= 0, \end{aligned}$$

which equations (in this and in all other cases) are changeable by successive substitution into the following:

$$\begin{aligned} b_0 e_1 + c_0 c_2 + e_0 b_3 + f_0 &= 0 \\ a_1 e_1 + b_1 c_2 + c_1 b_3 + e_1 &= 0 \\ f_2 e_1 + a_2 c_2 + b_2 b_3 + c_2 &= 0, \end{aligned}$$

from which equations e_1 , c_2 , and b_3 can be determined, and thence, by restitution, e_0 , c_0 , and b_0 . The original equation is now reduced to

$$(c_0 e_2 + e_0 c_3 + f_0 b_4 + a_0) Q_0 + (e_0 e_3 + f_0 c_4 + a_0 b_0 + b_0) Q_1 = l_0,$$

which has been solved. With regard to the notation of such questions as the preceding, observe

1. That it will very often be found convenient to write such equations as the preceding in the form

$$a_0 P_0 + b_1 P_1 + c_2 P_2 + e_3 P_3 + f_4 P_4 = 0,$$

expressing the coefficient of P_m by the function which it is, not of x , but of $\alpha^m x$.

2. That in carrying on investigations connected with periodic equations, it will often be useful to write them round a circle drawn upon the paper, instead of in the usual way.

3. That in questions of common Algebra, which have reference to elimination, &c., from equations of the first degree, a form of notation derived from analogy will frequently furnish help to the memory: for instance, the following

$$\begin{aligned} ax + b'x' + c''x'' + e'''x''' &= h \\ a'x' + b''x'' + c'''x''' + ex &= h' \\ a''x'' + b'''x''' + cx + e'x' &= h'' \\ a'''x''' + bx + c'x' + e''x'' &= h''' \end{aligned}$$

will be the best mode of writing such equations.

The preceding solution is, of course, to be adopted only in cases where the disappearance of the numerator and denominator of the result obtained from the successive equations shows that a continuous arbitrary function enters the solution.

When the equations which determine b_0 , c_0 , &c. give indeterminate results, one of them may be assumed at pleasure (say $b_0 = 1$), and c_0 and e_0 must be determined from any two of the equations. If the result be still indeterminate, let $c_0 = 1$, and determine e_0 from one of the equations.

(236.) The equation*

$$a_0 \phi m_0 x + a_1 \phi m_1 x + \dots = k_0 + k_1 x + k_2 x^2 + \dots$$

admits of an algebraical resolution, whether we suppose

* A particular case of this equation is cited by Sir J. Herschel (Edition of *Spence*, &c. p. xxviii.) as having been found among the papers of Mr. Spence.

both sides finite, or one or both infinite in the number of their terms. If we assume

$$\phi x = K_0 + K_1 x + K_2 x^2 + \dots,$$

make the substitutions on the first side of the equation, and equate corresponding terms, we find

$$K_0 \Sigma a = k_0 \quad K_1 \Sigma a m = k_1 \quad K_2 \Sigma a m^2 = k_2, \text{ \&c.,}$$

where

$$\Sigma a m^m \text{ means } a_0 m_0^m + a_1 m_1^m + \dots$$

Hence

$$\phi x = \frac{k_0}{\Sigma a} + \frac{k_1}{\Sigma a m} x + \frac{k_2}{\Sigma a m^2} x^2 + \dots$$

(237.) The equation

$$\phi x \cdot \phi \alpha x \cdot \dots \cdot \phi \alpha^{n-1} x = \beta x,$$

where βx is a form of $\xi \alpha x$, has for its general solution

$$\phi x = (\beta x)^{\frac{1}{n}} \frac{\theta x}{\theta \alpha x}.$$

But it must be observed, that the ambiguity of the second side sometimes leads to results of this kind, that some of the quantities $\phi x, \phi \alpha x, \dots$ must be considered as belonging to one of the forms, and some to others. This is always the case when the n th root can actually be extracted, and when, as may happen, the root itself, absolutely considered, is not a form of $\xi \alpha x$. For instance, suppose it required to find the curve whose ordinates equidistant from the axis of x on either side form a rectangle equal to the square of their common abscissa. The equation of the curve being $y = \phi x$, we have

$$\phi(x) \times \phi(-x) = x^2 \quad \phi x = \sqrt{x^2} \frac{\theta x}{\theta(-x)},$$

which, in its present form, appears to satisfy the conditions; but the form in question is, if θx be rational, the equation of two distinct curves denoted by

$$\phi x = x \frac{\theta x}{\theta(-x)} \quad \phi x = -x \frac{\theta x}{\theta(-x)},$$

which can only be considered as the same curve under an extension of analysis, by which any number of curves may be contained under one equation. Taking one ordinate off each curve, the condition is satisfied; but taking both from the same, we have $\phi x \times \phi(-x) = -x^2$ instead of x^2 . To get a curve which satisfies the condition within the common meaning of the phrases, we

must let $\frac{\theta x}{\theta(-x)}$ be an irreducible square root; that is, let

$$\phi x = \sqrt{x^2} \sqrt{\frac{\theta x}{\theta(-x)}}, \text{ or } y^2 = x^2 \frac{\theta x}{\theta(-x)}.$$

Similarly, we find for the curve the rectangle of whose ordinates is constant and equal to b , when that of the abscissæ is constant and equal to a , the equation

$$y^2 = b \theta x \div \theta \left(\frac{a}{x} \right).$$

(238.) We shall now examine further the method of derivation of periodic functions. The form $\phi_{-1} \phi x$, which has been shown (33.) to contain periodic functions, does in reality contain every periodic function. For every such function of the n th order can be exhibited in the form $\phi^{-1} r \phi x$, where $r^n = 1$. But since the different inverses of a function ϕx may be obtained by solving the equation $\phi x = r y$ arithmetically as to form, we find that $\phi_{-1} \phi x$ and $\phi^{-1} r \phi x$ are the same.

Calculus of Functions. It has appeared, therefore, that the periodic functions are in all cases the results of performing an inverse operation upon any other form of the direct function, except that with which the inverse is convertible. But the preceding inversion is only one particular case of those which are possible; and it will appear from considerations similar to those employed in (31.), that if a direct (that is integral) algebraical expression be given, its complete inversion cannot be found without applying to every term in which there is a power of x , the factor unity in the form r^n , where n remains unknown until the inversion shows what root must be extracted.

We found the forms of periodic functions hitherto obtained by supposing a particular solution; and the derivation of a non-periodic from a periodic function, or *vice versa*, give a certain limited symbol of discontinuity. We may show how to extend that solution in the following way. Instead of supposing αx a particular solution of $\psi^n x = x$, let it not be so, and let $\phi \alpha \phi^{-1} x = \psi x$. Then we have

$$\phi \alpha^n x = \phi x,$$

or

$$\phi x = \theta \cos 2\pi \frac{\Lambda x}{n},$$

which being supposed, $\phi \alpha \phi^{-1} x$ is periodic. But, by actually performing the operation, all traces of αx disappear as follows.*

$$\begin{aligned} \phi^{-1} x &= \Lambda^{-1} \left(\frac{n}{2\pi} \cos^{-1} \theta^{-1} x \right) \\ \phi \alpha \phi^{-1} x &= \theta \cos 2\pi \frac{1}{n} \Lambda \alpha \Lambda^{-1} \frac{n}{2\pi} \cos^{-1} \theta^{-1} x \\ &= \theta \cos 2\pi \frac{1}{n} \left(\frac{n}{2\pi} \cos^{-1} \theta^{-1} x - 1 \right) \\ &= \theta \cos \left(\cos^{-1} \theta^{-1} x - \frac{2\pi}{n} \right), \end{aligned}$$

which is evidently a periodic function of the n th order, but is derived from $x - \frac{2\pi}{n}$, which is not a periodic function. At the same time it must be observed, that the preceding is equally a derivative of $\frac{2\pi}{n} - x$, and we should therefore state, as a theorem of some curiosity, that *periodic functions of all orders can be derived from periodic functions of the second order*, if the method above given did not lead to a more remarkable extension of our preceding views.

The equation $\psi^n x = x$ is solved when $\alpha^n x = x$, ψx being $\phi \alpha \phi^{-1} x$. That is, when $\alpha^n x = \phi^{-1} \phi x$; but if $\alpha^n x = \phi_{-1} \phi x$, (where ϕ_{-1} , as before, stands for an inconvertible inverse of ϕ) we have still

$$\psi^n x = \phi \phi_{-1} \phi \phi^{-1} x = x;$$

the above is an instance, for $\cos^{-1} x - 2\pi$ is one of the inconvertible inverses of $\cos x$. The form of periodic functions thus obtained is

$$\phi (\phi_{-1} \phi)^{\frac{1}{n}} \phi^{-1} x.$$

Thus, a periodic function of the n th order is

$$\theta e^{\left(\Lambda \theta^{-1} x + \frac{2m\pi\sqrt{-1}}{n} \right)} \text{ or } \theta \left(e^{\frac{2m\pi\sqrt{-1}}{n}} \theta^{-1} x \right),$$

* We do not use brackets; every functional operation is relative to the total result of all which precede in the order of operation.

which does not, however, differ from forms already obtained. Calculus of Functions.

(239.) The preceding attempt to derive a periodic from a non-periodic function terminated in the disappearance of the first mentioned; the following method gives the same result.

In the equation $\phi \alpha^n x = \phi x$, let $\phi = \psi \Lambda$, which gives $\psi (x - n) = \psi x$, of which r^n is a particular solution when $r^n = 1$. And since all the values of r are powers of some one or more amongst them, it follows that the general theorem deduced from the preceding is:

$$\text{if } \phi x = \theta (r^{\Lambda x}) \quad r^n = 1,$$

and if

$$\psi x = \phi \alpha \phi^{-1} x, \text{ then } \psi^n x = x,$$

αx being any function whatever, and Λx its exponential

inverse. The resulting value of ψx is $\theta \frac{1}{r} \theta^{-1} x$.

(240.) We shall now consider the equation

$$\psi x + \psi \alpha x + \dots + \psi \alpha^n x = 0,$$

where αx is not periodic. If we assume $k^{-\Lambda x}$ as a particular solution, we find

$$a_0 + a_1 k + a_2 k^2 + \dots + a_n k^n = 0;$$

and if $k_1, k_2, \&c.$ be the roots of this equation, the general solution of the preceding is

$$\xi_1 \alpha x \cdot k_1^{-\Lambda x} + \xi_2 \alpha x \cdot k_2^{-\Lambda x} + \dots$$

in which there are n arbitrary functions, unless the equation have one or more sets of equal roots.

In the case of a couplet of equal roots, the particular solution corresponding to them is

$$(\xi_1 \alpha x + \Lambda x \xi_2 \alpha x) k_1^{-\Lambda x}.$$

In the case of a triplet of equal roots, the solution is

$$(\xi_1 \alpha x + \Lambda x \xi_2 \alpha x + (\Lambda x)^2 \xi_3 \alpha x) k_1^{-\Lambda x},$$

and so on.

The preceding equation shows the connection between functional equations and equations of differences very completely. In fact, if we denote any function ϕx by $\psi \Lambda x$, &c., the equation

$$\beta x \phi x + \beta_1 x \phi \alpha x + \beta_2 x \phi \alpha^2 x + \dots = \nu x$$

may be immediately reduced to

$$B x \psi x + B_1 x \psi (x-1) + B_2 x \psi (x-2) + \dots = N x,$$

which is a common equation of differences. There is no occasion, therefore, to dwell further upon this case, as we may refer the reader to all works on equations of differences.

(241.) Let

$$\beta x + \beta_1 x \psi x + \beta_2 x \psi^2 x + \dots + \beta_n x \psi^n x = 0.$$

Assume $\psi x = \phi \alpha \phi^{-1} x$, where α is any given function. Then, by substitution, and writing ϕx for x , we have

$$\beta \phi x + \beta_1 \phi x \cdot \phi \alpha x + \dots + \beta_n \phi x \phi \alpha^n x = 0,$$

which may in various cases be reduced to the last form; and it would appear at first as if we might get as many distinct solutions as we can assign forms of αx . But this does not follow; for since every function can be made a derivative of any given function, it may happen that any two solutions, $\phi_1 \alpha_1 \phi_1^{-1}$ and $\phi_2 \alpha_2 \phi_2^{-1}$, may be the same. But the arbitrary function (which depends only on αx) may vary with the form which we assign to α .

We have already considered a particular case of the preceding process, in the method of finding periodic functions. In order to show generally the disappearance of αx , remember that the several steps are, 1. $\psi x =$

Calculus of $\phi \alpha \phi^{-1}x$. 2. $\phi x = \chi A x$. 3. An equation of differences, giving $\chi x = F x$, $\phi x = F A x$, (it must be remembered that, as far as we can assign them, the arbitrary functions are also functions of $A x$.) $\phi^{-1}x = A^{-1}F^{-1}x$, $\psi x = F A \alpha A^{-1}F^{-1}x = F(F^{-1}x - 1)$, or the function of which $F^{-1}x$ is the exponential inverse. Hence ψx appears to be altogether independent of αx . It is really so if the coefficients be constant, or if $F x$ is expressed, as will frequently happen, in the form $F_1 A x$, not containing x except through $A x$.

(242.) As an instance of the last, let us suppose

$$\psi^2 x - 2a\psi x + x = 0,$$

in which we immediately find

$$\begin{aligned}\phi x &= c r^{Ax} + c' r^{-Ax} \quad r = a + \sqrt{a^2 - 1} \\ \psi x &= \phi \alpha \phi^{-1}x = a x + \sqrt{a^2 - 1} \sqrt{x^2 - C} \\ &= \sqrt{C} \cos\left(\cos^{-1}a + \cos^{-1}\frac{x}{\sqrt{C}}\right),\end{aligned}$$

which fulfils the conditions. But the general solution of

$$\psi^2 x + a\psi x + b x = 0$$

depends upon the inversion of

$$\chi x = c r^x + c' r'^x, \text{ where } r r' = b;$$

and, generally, $\sum a_n \psi^n x = 0$ depends upon the inversion of $\sum c_n r^n = y$. It must be observed, however, 1. That the preceding equation always has one particular solution of the form $c x$, derived from taking one particular solution only of the form r^x , to the equation which gives χx . 2. That if the product of any two roots of $\sum a_n r^n = 0$ be equal to unity, a more general solution may be found, as in the particular case above, namely

$$\frac{1}{2}\left(r + \frac{1}{r}\right)x + \frac{1}{2}\left(r - \frac{1}{r}\right)\sqrt{x^2 - C},$$

where r is one of the roots in question.

(243.) The equation

$$x^0(\psi x)^{a_1}(\psi^2 x)^{a_2} \dots (\psi^n x)^{a_n} = 1$$

may be solved as follows. Let $\psi x = \phi \alpha \phi^{-1}x$, and take the logarithm of the result, which gives

$$a_0 \lambda \phi x + a_1 \lambda \phi \alpha x + \dots + a_n \lambda \phi \alpha^n x = 0 \dots (\lambda \phi),$$

which gives

$$\lambda \phi x = \sum c_m r_m^{Ax},$$

where r_m is a root of

$$a_0 + a_1 r + \dots + a_n r^n = 0;$$

the form of the solution is

$$\lambda^{-1} F(F^{-1} \lambda x - 1)$$

in all cases in which the equation $(\lambda \phi)$ gives $\lambda \phi x$ as a function of $A x$; that is, in all cases at present soluble.

(244.) We shall here proceed to consider the manner in which the inconvertible inverses of a function must be used in connection with the direct function, when we take into consideration direct functions with more values than one.

1. If $f(a, b)$ and $\phi(a, b)$ be two different forms of the same function, so that when a and b are unambiguous,

$$f(a, b) = \phi(a, b),$$

it does not therefore follow that when we substitute instead of a and b functions with more values than one, that any value of a combined with any other value of b will make the preceding equation true, unless we use the

same values of a and b on both sides of the equation. Hence, in

$$a b = c, \text{ which gives } a^{\frac{1}{m}} b^{\frac{1}{m}} = c^{\frac{1}{m}},$$

it is not true that any value of $a^{\frac{1}{m}}$ multiplied by any value of $b^{\frac{1}{m}}$ may be equated with any value of $(a b)^{\frac{1}{m}}$, but only with that value which arises from using the same forms of a and b as those from which the $a^{\frac{1}{m}}$ and $b^{\frac{1}{m}}$ in question were derived in an arithmetical form. If one of the primitive m th roots of unity be called r , and if a be considered as $a r^{pm}$ and b as $b r^{qm}$, then $a b$ on the second side must be considered as $a b r^{(p+q)m}$.

2. When $y = \phi x$ gives $x = \phi_{-1} y$, this equation is not identically true, unless we give y one particular form for each particular form of ϕ_{-1} . In fact, as we have seen, $\phi_{-1} \rho \phi x$ is the representation of x , as derived from inversion and reinversion, where ρ is a symbol of a change of form without change of value.

3. When we take the function $\psi \phi_{-1} x$, we have different results according as we use one or another form of ϕ_{-1} , except when ψ admits of unambiguous representation in the form $\chi \phi$, in which case $\psi \phi_{-1} x$ is $\chi \phi \phi_{-1} x$ or χx .

4. If we assume $\chi x = \phi \psi x$, then $\chi_{-1} x = \psi_{-1} \phi_{-1} x$, and any form of ψ_{-1} applied to any form of ϕ_{-1} gives one of the forms of χ_{-1} . And if the forms of ϕ_{-1} , ψ_{-1} , and χ_{-1} can be found by giving different values to m , n , and p , as in

$$\phi_{-1} x = \Phi(m, x) \quad \psi_{-1} x = \Psi(n, x) \quad \chi_{-1} x = X(p, x),$$

then the equation $\chi_{-1} x = \psi_{-1} \phi_{-1} x$ is an equation of condition between m , n , and p .

5. If there be a constant c in ϕx which admits of several values, then we can only consider the introduction of different values as forming entirely different functions of x . For instance, one of the forms of

$1 + (1)^{\frac{1}{2}} x$ is a periodic function, and the other is not.

6. Let there be a function of x which has more values than one, and let us suppose it to be ϕx . If we make $\phi x = y$, we must remember that y is now either of the values of ϕx , and in every alteration and substitution which we make, we must remember that the general value of y must be used, and not the particular value, in every case where the general value of ϕx is used. For instance, let us suppose $a^x = y$, where the first side has as many values as there are units in the denominator of x . If we call m this denominator, then y being the arithmetical value of a^x , we have $a^x = (1)^{\frac{1}{m}} y$, or, which will do equally well, $a^x = (1)^x \cdot y$; the true expansion of a^x being

$$a^x = (1)^x \left\{ 1 + x + \frac{x^2}{2} + \dots \right\},$$

derived from the general binomial theorem

$$(1 + a)^x = (1)^x \left\{ 1 + x a + x \frac{x-1}{2} a^2 + \dots \right\}.$$

If then $l a$ and $l x$ be the arithmetical logarithms of a and x , we find

$$e^{(l a + 2\pi m \sqrt{-1})x + 2n\pi \sqrt{-1}} = (1)^x e^{l y + 2\pi p \sqrt{-1}},$$

an equation which is true for all values of m , n , and p , provided that value of $(1)^x$ be taken which corresponds

Calculus of Functions. to the given value of m ; provided, in fact, we take $\varepsilon^{2\pi m x \sqrt{-1}}$ for $(1)^x$; that is, we have

$$\varepsilon^{(la+2\pi m \sqrt{-1})x+2\pi n \sqrt{-1}} = \varepsilon^{ly+2\pi m x \sqrt{-1}+2\pi p \sqrt{-1}},$$

an equation which is certainly true, and might be verified by actual expansion. But we are not at liberty to assert the equality of the exponents, unless we make $n=p$.

The theorems which have been lately proposed* with respect to the logarithms of unity, amount, in fact, to equating the preceding exponents without the restriction upon the value of $(1)^x$ above alluded to, and the assertion that x , as thus derived, is the real solution of $a^x = y$. For that process gives

$$(la + 2\pi m \sqrt{-1})x + 2\pi n \sqrt{-1} = ly + 2\pi m'x \sqrt{-1} + 2\pi p \sqrt{-1},$$

or

$$x = \frac{ly + 2\pi v \sqrt{-1}}{la + 2\pi w \sqrt{-1}},$$

where v and w are any whole numbers. If $a = \varepsilon$ and $y = 1$, this gives for the logarithms of unity

$$\frac{2\pi v \sqrt{-1}}{1 + 2\pi w \sqrt{-1}} \text{ or } \frac{2\pi v}{2\pi w - \sqrt{-1}},$$

(245.) The examples in (240, &c.) are closely connected with the history of the methods employed in this branch of Mathematics, on which we shall now introduce some remarks. Every expression of Algebra must necessarily give an idea rather of a set of operations to be performed upon quantities than of the quantity itself

* With great respect for the talents of Mr. Graves and of Sir William Hamilton, as well as of some distinguished foreigners, whom they state to have produced coincident results, we must suppose them to have fallen into this error, directly or indirectly, until some one among them produces a more explicit statement of their fundamental conventions, pointing out whether they employ those in common use or not. After an attentive perusal of both papers by Mr. Graves, that in the *Philosophical Transactions* of 1829, and that in the *Fourth Report of the British Association*, we do not know whether the assertion, that the logarithm of 1 is

$\frac{2\pi v}{2\pi w - \sqrt{-1}}$ means, that

$$\left(1 + 1 + \frac{1}{2} + \frac{1}{2 \cdot 3} + \dots\right)^{\frac{2\pi v}{2\pi w - \sqrt{-1}}} = 1 \dots (A)$$

or not.

To find a relation between x and y in the equation $a^x = y$, Mr. Graves supposes $a = \cos \theta + \sqrt{-1} \sin \theta$, and hence concludes that $a^x = f(xf^{-1}a)$ where $f\theta = \cos \theta + \sqrt{-1} \sin \theta$. But this is equally true where $f\theta = e^{c\theta}$, c having any value whatever, as appears sufficiently if the common processes of Algebra be true. If they be not true, we cannot see how the theorem

$$f\theta = \text{the common expansion of } \varepsilon^{\theta \sqrt{-1}}$$

(which is admitted on all sides) is true.

If we were to hear an objection to the equation $\varepsilon^{2\pi v \sqrt{-1}} = 1$, grounded on an objection to impossible quantities, we might appeal to the actual expansion

$$1 - \frac{\pi^2 v^2}{2} + \dots + (2\pi v - \dots) \sqrt{-1} = 1,$$

or $1 + 0 \times \sqrt{-1} = 1$. Is it really asserted that the expansion of the left-hand side of A would give the right-hand side? If so, let it be shown, and our objections of course fall to the ground. But in the mean while we hold it safer, when two methods give discordant results, to make the better known of the two throw suspicion upon the other.

which results from performing these operations. Nothing is more difficult to a beginner in Algebra than the necessity of considering a complicated literal expression as the value of an unknown quantity, instead of the exhibition of the processes by which the value is to be obtained, so soon as the subjects of operation shall have received specific values. Before the introduction of specific symbols for indeterminate known quantities by Vieta, the language and methods of algebraists were fast approaching to a *calculus of operations*, distinguished from a *calculus of functions* by the absence of symbols, but on this very account approximating more perhaps to the consideration of the *functional* than of the ordinary algebraic character of expressions. "*Solve quamvis questionem . . . serva operationes . . . et habebis regulam de modo pro omni consimili questione*" are the words of Cardan, which comprise his method of making one arithmetical example point out the solution of another. When the literal expressions of Vieta were introduced, the object seems to have been to forget as much as possible the method of formation which each expression carried with it, unless at the moment when a new operation was to be performed. And thus it became necessary to describe operations in words when it was desired to point the attention upon a function, as such; and the rule of Cardan, above cited, became as necessary in the Algebra of Vieta as in pure Arithmetic, simply because a confined mode of viewing the subject had conventionally invested the results of the former with the character of the latter. Hence rules and processes took the place of expressions; and our readers must remember that it was, and still is, usual to deduce the roots of an equation of the second degree *de novo* on every separate occasion. This anxiety to distinguish the operations of Algebra from the symbols which conventionally represented the operations themselves, is strikingly manifest in the older algebraists. Take the following example of a process from Bartholinus.*

Exempla additionis simplicium.

$$\text{Add. } \begin{cases} a \\ b \end{cases}$$

$$\text{Summa } a + b.$$

The Differential Calculus, or rather the Integral Calculus, first turned attention expressly on the forms which will satisfy given conditions, considered independently of values. The celebrated isoperimetrical problems of the Bernoullis are among the earliest of the kind; but before this the *Principia* of Newton had appeared, full of questions in which *law* and not *quantity* was the subject of investigation. The considerations entering into physical questions made a more functional algebra absolutely necessary: the pure mathematician was rapidly becoming (out of Geometry) a machine for solving numerical equations, summing arbitrarily formed series, and trying to square the circle, when the call to follow up the researches of Newton threw him upon difficulties which were not of his own making.

(246.) We cannot find it stated precisely who first used the indeterminate functional symbol. But this is a matter of little consequence, since the time when real questions of the inverse functional calculus began to be agitated must date from the researches of Euler, Lambert, D'Alembert, Lagrange, Monge, and Laplace. In

Calculus of the year 1760 Lagrange* integrated the equation which Functions. we should represent by

$$\Sigma p_n \phi(a + b \alpha^n x) = \xi \alpha x,$$

where $p_0, p_1, \&c.$ are forms of $\xi \alpha x$, and $\alpha x = a' + b'x$. The process consisted in a developement of $\phi(a + b \alpha^n x)$ by Taylor's theorem, and had no close connection with the difficulties of the subject. The next step was made by Monge, as we shall proceed to state.

(247.) The solution of an ordinary differential equation is shown by the direct method of forming such equations to amount to the inquiry what function of x and y must be constant in order that a given relation

between $x, y, \frac{dy}{dx}$, &c. may exist. The existence of a

functional relation between two quantities is necessary and sufficient to the fulfilment of the condition, that the one shall be constant when the other is so. A partial differential equation, besides being known to arise from the elimination of an arbitrary function, is shown to depend upon two simultaneous differential equations of the common kind, giving two functions of the variables, of which it is sufficient for the conditions that they should be constant together; that is, that one should be any function of the other. The determination of the form of the arbitrary function from given conditions leads of course to questions in the Inverse Calculus of Functions. To take a very simple case, suppose it is required to describe a surface of revolution with a given axis, which shall pass through a given curve. This amounts geometrically to describing through every point of the curve a circle perpendicular to the axis, and having its centre in the axis. This, it is evident, can be done, whether the given curve be continuous or discontinuous. If the axis of revolution be made that of z , and axes of x and y be taken perpendicular to it and to each other, the differential equation of the surface in question is

$$y \frac{dz}{dx} = x \frac{dz}{dy},$$

which is common to all surfaces of revolution having the axis in question, and its complete integral is

$$z = \theta(x^2 + y^2).$$

If αx and βx be the values of y and z , corresponding to the ordinate x of the curve in question, the condition that the surface must pass through the curve requires that

$$\beta x = \theta(x^2 + (\alpha x)^2)$$

and the determination of the form of θ depends on the inversion of $x^2 + (\alpha x)^2$.

The preceding method will frequently give the answer required, because the importance of simple inversion has led to the consideration of many cases, and inversion has been invented (the process being practically supplied by tabulation) where the ordinary processes of Arithmetic have not been found sufficient. But in a great number of cases the integral itself cannot be otherwise determined than by eliminating the subject of an arbitrary

function from between two equations: for instance, Calculus of take the manner in which Monge expressed the equation Functions. of a *developable* surface, where z is a function of x and y , obtained by eliminating V between the two following,

$$z - \psi V = (x - V) \frac{d\psi V}{dV}$$

$$y - \phi V = (x - V) \frac{d\phi V}{dV},$$

where ϕ and ψ may be any forms whatsoever.

(248.) Let there be a function z defined as follows:

$$z = \phi \alpha(x, y) + \psi \beta(x, y),$$

where α and β are known forms, and ϕ and ψ are to be so determined, that

$$z = f x \text{ when } y = F x \text{ } \{ f, F, f_1, F_1$$

$$z = f_1 x \text{ when } y = F_1 x \text{ } \}$$
 being known.

Hence we have the following equations,

$$f x = \phi \alpha(x, F x) + \psi \beta(x, F x)$$

$$f_1 x = \phi \alpha(x, F_1 x) + \psi \beta(x, F_1 x).$$

Let $\beta(x, F x) = u$ give* $x = \beta u$, which gives

$$f \beta u = \phi \alpha(\beta u, F \beta u) + \psi u,$$

from which the form of ψ is known, when that of ϕ is known; and by following a process exactly similar with the second equation, making $\beta(x, F_1 x) = u$, give

$x = \beta_1 u_1$, we find

$$f_1 \beta_1 u_1 = \phi \alpha(\beta_1 u_1, F_1 \beta_1 u_1) + \psi u_1,$$

and as these equations must be identically true, whatever we may write for u_1 or u , write u for u_1 in the second, and subtract it so altered from the first, which gives

$$f \beta u - f_1 \beta_1 u = \phi \alpha(\beta u, F \beta u) - \phi \alpha(\beta_1 u, F_1 \beta_1 u),$$

an equation of the form

$$\phi \mu x - \phi \nu x = \omega x,$$

which may be reduced to the form

$$\phi x = \beta x + \gamma x \phi \alpha x,$$

already considered. The preceding process will apply equally well to

$$z = a_{x,y} + b_{x,y} \phi \alpha(x, y) + c_{x,y} \psi \beta(x, y),$$

and will give a result of similar form; as also will

$$z = a_{x,y} + \phi \{ b_{x,y} + c_{x,y} \psi \beta(x, y) \},$$

which must be previously reduced to the form

$$\phi^{-1}(z - a_{x,y}) = b_{x,y} + c_{x,y} \psi \beta(x, y).$$

(249.) The equation

$$z = \Sigma \gamma_n(x, y) \psi_n \alpha_n(x, y),$$

in which there are n undetermined functions, $\psi_1, \psi_2, \&c.$ to be determined by n conditions of the form

$$z = f_n x \text{ when } y = F_n x,$$

may be reduced by the preceding process to n equations, containing each a term of the form $\omega u \psi_1 u$: elimination reduces these to $n - 1$ equations, wanting $\psi_1 u$. A repetition of the process eliminates $\psi_2 u$, and so, till we have two equations only, from which the elimination of $\psi_{n-1} u$ leaves an equation of the form

* βx was the notation proposed by Monge for what we call $\beta^{-1} x$ (a notation introduced, we believe, by Sir John Herschel.) It will be convenient to reserve the former for particular inversions required by problems, as in the present case.

* *Misc. Taur.*, vol. iii. We cite here from the Memoir of Monge already cited. Several writers have used expressions which would lead us to infer they thought Lagrange had solved a more general case. If it be so, we cannot see it from Monge's account, and we have not had access to the original. In the *Memoirs of the Analytical Society*, p. 96, it is stated that Lagrange had reduced the question to the solution of a transcendental equation, such as those in (242.), which might be done.

Calculus of
Functions.

$$\psi_n \mu u + \omega u \psi_n \nu u + \omega_1 u = 0.$$

(250.) The process by which Monge reduced the equations he thus obtained to equations of differences, or rather generalized the conditions implied in equations of differences so as to raise them to functional equations, is as follows. Taking the difference of x to be that by which it increases when it becomes αx , or

$$\Delta x = \alpha x - x,$$

and y a function of x to be determined, he defines Δy by $\psi \alpha x - \psi x$,

$$\Delta^2 y \text{ by } \psi \alpha^2 x - \psi \alpha x - (\psi \alpha x - \psi x),$$

and so on. Thus the equation

$$\Delta y + A y + B = 0$$

answers to what, in our notation, would be

$$\psi \alpha x = (1 - A) \psi x - B.$$

We shall give, in the words of Monge, his integration (as we must now call it) of the preceding equation, for the cases where $\alpha x = x + a$, $\alpha x = a + (b + 1)x$, and $\alpha x = a x^n$. It is extracted from the ninth volume of the *Memoirs of the Academy of Sciences*, page 357. It must be observed, that what we call 2π , Monge calls π .

"PROBLÈME V.

"Intégrer complètement l'équation $\Delta y + A y + B = 0$, dans le cas où la différence finie de la variable principale seroit 1°. = constante = a ; 2°. = $a + bx$; 3°. = $a x^n - x$.

"SOLUTION.

"Soit fait $A y + B = e^u$; ce qui donnera

$$\frac{e^{u+\Delta u} - e^u}{A} + e^u = 0,$$

et par conséquent $\frac{\Delta u}{L \cdot (1 - A)} = 1$; soit x la variable

principale: cela posé, pour le premier cas, on a $\Delta x = a$ ou $\frac{\Delta x}{a} = 1$ et par conséquent $\frac{\Delta u}{L \cdot (1 - A)} =$

$\frac{\Delta x}{a}$, dont l'intégrale sera $u = \frac{x L \cdot (1 - A)}{a}$; et, mettant

pour u sa valeur, $L \cdot (A y + B) = \frac{x}{a} L \cdot (1 - A)$, ou

enfin $A y + B = (1 - A)^{\frac{x}{a}}$; or nous avons vu que, pour compléter cette intégrale, il falloit ajouter la fonction arbitraire $\phi\left(\sin \frac{\pi x}{a} \text{ et } \cos \frac{\pi x}{a}\right)$; donc l'intégrale complète, dans le premier cas, sera

$$A y + B = (1 - A)^{\frac{x}{a}} \times \phi\left(\sin \frac{\pi x}{a} \text{ et } \cos \frac{\pi x}{a}\right).$$

"Pour le second cas, on fera $a + bx = e^w$, d'où l'on tirera $\Delta w = L \cdot (b + 1)$, ou $\frac{\Delta w}{L \cdot (b + 1)} = 1$; ainsi,

ayant d'ailleurs $\frac{\Delta u}{L \cdot (1 - A)} = 1$, on aura $\frac{\Delta u}{L \cdot (1 - A)} =$

$\frac{\Delta w}{L \cdot (b + 1)}$, dont l'intégrale sera $u = w \frac{L \cdot (1 - A)}{L \cdot (b + 1)}$,

et, mettant pour u et w leurs valeurs,

$$L \cdot (A y + B) = L \cdot (a + bx) \frac{L \cdot (1 - A)}{L \cdot (b + 1)};$$

or nous avons vu (Prob. III.) que la fonction arbitraire qu'il faut ajouter pour compléter l'intégrale, est

$$\phi\left(\sin \frac{\pi L \cdot (a + bx)}{L \cdot (b + 1)} \text{ et } \cos \frac{\pi L \cdot (a + bx)}{L \cdot (b + 1)}\right);$$

donc on aura, pour intégrale complète,

$$L \cdot (A y + B) = L \cdot (a + bx) \frac{L \cdot (1 - A)}{L \cdot (b + 1)}$$

$$+ L \cdot \phi\left(\sin \frac{\pi L \cdot (a + bx)}{L \cdot (b + 1)} \text{ et } \cos \frac{\pi L \cdot (a + bx)}{L \cdot (b + 1)}\right),$$

et, passant aux nombres,

$$A y + B = (a + bx)^{\frac{L \cdot (1 - A)}{L \cdot (b + 1)}}$$

$$\times \phi\left(\sin \frac{\pi L \cdot (a + bx)}{L \cdot (b + 1)} \text{ et } \cos \frac{\pi L \cdot (a + bx)}{L \cdot (b + 1)}\right).$$

"Pour le troisième cas; c'est à dire, lorsque l'on a $\Delta x = a x^n - x$, on fera $x = e^w$, d'où l'on tirera $\Delta w =$

$(n - 1)w + L a$: faisant ensuite $(n - 1)w + L a = e^u$

on aura $\Delta w' = L \cdot n$, ou $\frac{\Delta w'}{L \cdot n} = 1$; or on a $\frac{\Delta u}{L \cdot (1 - A)}$

$= 1$; par conséquent on aura $\frac{\Delta u}{L \cdot (1 - A)} = \frac{\Delta w'}{L \cdot n}$, dont

l'intégrale est $u = w' \frac{L \cdot (1 - A)}{L \cdot n}$; et, mettant pour u

et w' leurs valeurs,

$$L \cdot (A y + B) = L \cdot L \cdot a x^{n-1} \times \frac{L \cdot (1 - A)}{L \cdot n};$$

ajoutant enfin la fonction arbitraire du Problème IV., on aura, pour intégrale complète,

$$L \cdot (A y + B) = L \cdot L \cdot (a x^{n-1}) \frac{L \cdot (1 - A)}{L \cdot n}$$

$$+ L \cdot \phi\left(\sin \text{ et } \cos \frac{\pi L \cdot L \cdot a x^{n-1}}{L \cdot n}\right)$$

enfin, passant aux nombres,

$$A y + B = (L \cdot (a x^{n-1}))^{\frac{L \cdot (1 - A)}{L \cdot n}}$$

$$\times \phi\left(\sin \text{ et } \cos \frac{\pi L \cdot L \cdot a x^{n-1}}{L \cdot n}\right).$$

The method by which Monge discovers the nature of the arbitrary function is, in fact, repeated again in the above, though not directly alluded to, by finding x and ω in such a manner that a given increase of ω shall increase x by $\alpha x - x$, or *vice versa*; he then makes the sine and cosine of ω multiplied by 2π , and divided by the given increase, the subjects of the arbitrary function, having first expressed ω in terms of x . In fact,

a being the increase of ω , $-\frac{\omega}{a}$ is the exponential inverse

of αx , as we have termed it. The Memoir of Monge cited is certainly worth the attention of the advanced student; but after all, it is an effort of genius striving to force a mathematical method beyond its powers.

(251.) While Monge was employed in generalizing the Calculus of variables with constant differences into a Calculus of Functions, Laplace, as he informed Monge at the time, was reducing functional equations to equations of constant differences, in the manner which has been already described. A little before the same time,*

* Lambert's first ideas were published in the *Acta Helvetica* in 1758; Lagrange's theorem in the *Memoirs of the Academy of Sciences* for 1768; Laplace's method for functional equations in the *Memoirs of the Savans Etrangers* for 1773.

Calculus of
Functions.

Calculus of Functions. Lambert communicated to Euler and Lagrange some expansions of the root of a trinomial equation in series, which the latter generalized into his celebrated theorem, the greatest step yet made in the calculus of inversion. It is not, however, of any service in our present pursuit, owing to the unlimited number of terms which always occurs. And, in the method of Laplace, many of the integrations of equations of differences which can be effected are unserviceable, owing to the appearance of a sum or product, the number of terms of which is a function of x .

(252.) The method of Laplace can only apply, with perfect generality, to cases in which the unknown function has not more than two subjects; for if $\alpha x = u_x$, and $\beta x = u_{x+1}$, which is always possible, subject to the integration of an equation of differences, it does not follow that γx will be u_{x+n} , &c.; but if this happen, the method applies.

In the *Memoirs of the Analytical Society* already cited, it is shown how, by means of equations of partial differences, to reduce more extensive classes of functional equations to depend upon finite integration. The following is a sketch of the method.

Let the proposed equation be

$$F(x, \phi \alpha x, \phi \beta x, \phi \gamma x) = 0 \dots (1),$$

where F , α , β , and γ are known forms, and ϕx is to be determined. Assume a function of v and z , namely, $P_{v,z}$, to be determined by the following conditions:

$$\alpha x = P_{v,z}, \quad \beta x = P_{v-1,z}, \quad \gamma x = P_{v,z-1},$$

or

$$\beta^{-1} P_{v-1,z} = \alpha^{-1} P_{v,z} \dots (2) \quad \gamma^{-1} P_{v,z-1} = \alpha^{-1} P_{v,z} \dots (3),$$

giving

$$P_{v,z} = \Pi(v, z, \theta(\cos 2\pi v, z)) \dots (2')$$

$$P_{v,z} = \Pi_1(v, z, \theta_1(v, \cos 2\pi z)) \dots (3').$$

That Π and Π_1 are known forms is the assumed integration; and θ , θ_1 are arbitrary functions *subject only to the conditions $\Pi = \Pi_1$, and that of not inverting the cosine, provided always these two conditions agree.* But we have

$$x = \alpha^{-1} P_{v,z},$$

and substitutions in (1) give (if $\phi P_{v,z} = \Phi_{v,z}$)

$$F(\alpha^{-1} P_{v,z}, \Phi_{v,z}, \Phi_{v-1,z}, \Phi_{v,z-1}) = 0 \dots (4),$$

another equation of differences, which we will suppose integrated in the form

$$\Phi_{v,z} = F_1(v, z, \Theta \cos 2\pi v, \Theta_1 \cos 2\pi z) \dots (5),$$

F_1 being known by integration, and Θ and Θ_1 being arbitrary functions, *which do not invert the cosine.* From (2') and (3') v and z can be expressed in the form

$$v = \Pi P_{v,z} \quad z = \Pi_1 P_{v,z},$$

giving

$$\phi P_{v,z} = F_1(\Pi P_{v,z}, \Pi_1 P_{v,z}, \Theta \cos 2\pi \Pi P_{v,z}, \Theta_1 \cos 2\pi \Pi_1 P_{v,z})$$

$$\phi x = F_1(\Pi x, \Pi_1 x, \Theta \cos 2\pi \Pi x, \Theta_1 \cos 2\pi \Pi_1 x).$$

(253.) The words which we have put in italics relate to points which have not been adverted to by the distinguished writer from whom we cite, (indeed, it hardly lay in his road to do so); and in the perfect impossibility of treating even the most simple case in all its generality, we are compelled to resort to analogy, and even to conjecture. But as our object is to create doubt, not to establish certainty, such a method is more than sufficient, since the simple word of denial is a sufficiently

VOL. II.

conclusive argument against whatsoever is not established by demonstration.

The simultaneous existence of any number of equations may be of two kinds, very distinct in their character, though not always distinguished. The first, to which the name more properly belongs, (but which is not the common species,) and which we shall call *dependent coexistence*, is where we require that one or more of the equations should be true *only* when the rest are true, but not without them, *necessarily*. Instead of separate equations,

$$V_1 = 0 \quad V_2 = 0 \dots W_1 = 0 \quad W_2 = 0 \dots,$$

where the existence of the first set does not necessarily make that of the second follow, the dependent coexistence only requires that

$$c_1 V_1 + c_2 V_2 + \dots + h_1 W_1 = 0$$

$$c'_1 V_1 + c'_2 V_2 + \dots + h'_1 W_2 = 0$$

$$\dots \dots \dots$$

where the constants may be, and generally will be, determinate. On the other hand, independent coexistence requires the absolute existence of all the first sets of equations together. The want of sufficient nominal distinction between these two different things creates a difficulty in the Calculus of Variations well known to those who remember the early obstacles to their progress. But we proceed to the bearing of this distinction upon our subject.

(254.) A question may arise as to the equations (2) and (3), whether their coexistence is dependent or independent. If the first, the two equations are equivalent only to one; and the solution, though correct, (for the dependent includes the independent case,) is very limited. That the solutions of the independent case are much more limited than those of the other is sufficiently evident; but we shall apply the distinction to the common theory of differential equations; that is, we shall digress to show that the arbitrary function appears in the solution of *dependently* coexistent differential equations, even where no partial differentiations occur. That the introduction of the arbitrary function into *partial* differential equations may be referred to this circumstance follows from the well-known method of deducing their integration.

Let $\phi(M, N) = P$ be the result of an integration, where M , N , and P are respectively functions of x , y , and z . Common differentiation shows that

$$\frac{d\phi}{dM} dM + \frac{d\phi}{dN} dN = dP,$$

or that the preceding condition is sufficient for the dependent coexistence of

$$dM = 0, \quad dN = 0, \quad dP = 0,$$

or

$$\frac{dM}{dx} dx + \frac{dM}{dy} dy + \frac{dM}{dz} dz = 0, \text{ \&c., \&c.,}$$

in which the appearance of the complete differentia. form may be lost by suppression of factors. But let us consider independently the coexisting equations

$$\frac{dy}{dt} - x = 0, \quad \frac{dx}{dt} - y = 0,$$

the independent coexistence of which implies that

$$x = ce^t + c'e^{-t}, \quad y = ce^t - c'e^{-t},$$

which latter equations will be dependently coexistent when

Calculus of
Functions.

$$\frac{dc}{dt} \epsilon^t + \frac{dc}{dt} \epsilon^{-t} = \theta t \left(\frac{dc}{dt} \epsilon^t - \frac{dc}{dt} \epsilon^{-t} \right),$$

where θt is any function whatsoever. Here c may be assumed as any function of t , and c' determined accordingly. Let $c = \psi t$, then the elimination of ψt between the two equations which give x and y , leaves one relation between x , y , and t , containing the arbitrary function θt ; which is sufficient to satisfy the conditions. Or we may multiply the second of the given equations by θt , and add it to the first, which gives

$$\frac{dy}{dt} + \theta t \frac{dx}{dt} = x + y \theta t.$$

Assume $y = \psi t$, which gives by the common process

$$x = \epsilon^{\int \frac{dt}{\theta t}} \int \epsilon^{-\int \frac{dt}{\theta t}} \left(\psi t - \frac{\psi' t}{\theta t} \right) dt,$$

in which it is easily verified that $\psi' t = x$ gives $\frac{dx}{dt} = \psi t$. The elimination of ψt then gives one relation between x , y , and t , with the arbitrary function θt . The above method shows that we have implicitly proceeded step by step in the formation of a partial differential equation more complicated than the circumstances require, and it is known that a given set of dependently coexistent equations may be made to arise from an infinite number of partial equations. But if we take the most simple partial differential equation which depends upon the two given equations, which is

$$y \left(\frac{dy}{dx} \right) + \left(\frac{dy}{dt} \right) = x,$$

we have the most simple form of the relation required, namely,

$$x^2 - y^2 = \theta (x + y \epsilon^{-t}),$$

subject to which it is generally true that y and x being functions of t , $\frac{dy}{dt} = x$, when $\frac{dx}{dt} = y$. There is, how-

ever, what we may call a *singular* solution for every particular form of θ , which deserves the attention of mathematicians, but is foreign to our present subject.

(255.) If we grant the equations (2) and (3) in (252.) to be dependently coexistent, the arbitrary function in the solution of the single equation which then connects the two must be neither of the form $\xi(v-1)$ or $\xi(z-1)$, but of the form $\xi(v-1, z-1)$. Supposing them independently coexistent, we come to the consideration of the two conditions:

1. $\Pi = \Pi_1$, which connects θ and θ_1 ;
2. Neither θx nor $\theta_1 x$ must invert $\cos x$.

Under what conditions these may be made to agree must remain a question; but the generality of the result will not be altogether destroyed by supposing arbitrary constants in the place of θ and θ_1 , owing to the final arbitrary functions Θ and Θ_1 . But the form given to these certainly appears too limited.

(256.) The following considerations will show that the preceding method must be further considered before it can be used with perfect safety. The coexistence of (2) and (3), if *independent*, makes v a function of z (for all assigned forms of θ and θ_1), determined by eliminating $P_{v,z}$ from (2') and (3'); that is, (4) is not an equation of partial differences, as supposed; if *dependent*, then only one value of $P_{v,z}$ results, whether we suppose it obtained from the single equation

$$(2) + c(3) = 0,$$

or by assigning such a relation between θ and θ_1 as shall make (2') and (3') identically the same equations. In either case, both v and z cannot be separately assigned in terms of $P_{v,z}$, which the subsequent solution requires. In either case, however, solutions may be obtained without difficulty when the arbitrary functions are supposed constant; but when they are not supposed constant, an equation of condition results between arbitrary functions.

When (2) and (3) are considered as independently coexistent, let the condition which must be assigned between θ and θ_1 be deferred, and the process continued to the end, as described. If the expression of v and z , by means of two equations, which are to be made only equivalent to one, leads to any indeterminate forms, the solution fails; if not, a relation may be assigned between the constants or arbitrary functions in the result, which will make the final value of ϕx a solution. But it must be observed that the elucidation of this point cannot be given in the present state of the theory of simultaneous equations of partial differences.

(257.) It would take more consideration than we can here give to decide *a priori* upon the preceding method; and the only examples in which the solution of the *dependent* equations (2) and (3) is possible are not conclusive, owing to the limited character of the functions which must be employed, and of the solutions obtained. We shall show, however, by an example, that the method cannot be employed, as given, without the assignment of a relation between the arbitrary quantities obtained.

Let the equation be

$$\phi x + \phi 2x = \phi 3x$$

$$x = P_{v,z}, \quad 2x = P_{v-1,z}, \quad 3x = P_{v,z-1},$$

$$P_{v-1,z} = 2 P_{v,z} \text{ or } P_{v,z} = \left(\frac{1}{2} \right)^v \theta = \Pi$$

$$P_{v,z-1} = 3 P_{v,z} \text{ or } P_{v,z} = \left(\frac{1}{3} \right)^z \theta_1 = \Pi_1,$$

and

$$\Phi_{v,z} + \Phi_{v-1,z} = \Phi_{v,z-1},$$

or

$$\Phi_{v,z} = \Theta^v \Theta_1^z \times \Theta_2$$

subject to the condition $1 + \frac{1}{\Theta} = \frac{1}{\Theta_1}$.

Assume θ and θ_1 arbitrary constants, and we have

$$\Pi x = \frac{\lambda \theta - \lambda x}{\lambda 2}, \quad \Pi_1 x = \frac{\lambda \theta_1 - \lambda x}{\lambda 3},$$

and assuming Θ , &c. to be constant, we have

$$\phi x = \Theta^{\frac{\lambda \theta - \lambda x}{\lambda 2}} \times \left(\frac{\Theta}{1 + \Theta} \right)^{\frac{\lambda \theta_1 - \lambda x}{\lambda 3}} \times \Theta_2 = V V_1 \Theta,$$

which gives

$$\phi 3x = V V_1 \Theta^{-\frac{\lambda 3}{\lambda 2}} \left(\frac{\Theta}{1 + \Theta} \right)^{-1} \Theta_2$$

$$\phi x + \phi 2x = \left\{ 1 + \Theta^{-1} \left(\frac{\Theta}{1 + \Theta} \right)^{-\frac{\lambda 2}{\lambda 3}} \right\} V V_1 \Theta_2,$$

which are not equal except when

$$1 + \Theta^{-1} \left(\frac{\Theta}{1 + \Theta} \right)^{-\frac{\lambda 2}{\lambda 3}} = \Theta^{-\frac{\lambda 3}{\lambda 2}} \left(\frac{\Theta}{1 + \Theta} \right)^{-1}.$$

(258.) The only method which we can perceive of

Calculus of
Functions.

Calculus of deducing a certain solution from the method in (252.) Functions. is as follows. Integrate (2) and (3), and assume θ and θ_1 , so as to make the two Π and Π_1 identically the same. Then find $\Phi_{v,x}$, as before; eliminate z between $P_{v,x}$ and $\phi P_{v,x}$, giving ϕx in terms of x and v . Then v is an arbitrary function of x , which becomes $v - 1$ when αx becomes βx , and remains the same when αx becomes γx . If we apply this method to the preceding equation, we find

$$P_{v,x} = \left(\frac{1}{2}\right)^v \left(\frac{1}{3}\right)^x = x$$

$$\phi P_{v,x} = \Theta^v \Theta_1^x \times \Theta_2 \quad 1 + \frac{1}{\Theta} = \frac{1}{\Theta_1}$$

$$\phi x = \Theta^v (2^v x)^{-\frac{\lambda \Theta_1}{\lambda^2}} \times \Theta_2,$$

which will be found to satisfy the conditions.

Two species of arbitrary functions are thus introduced; firstly, Θ_1 , which must not change when αx is changed, either into βx , or γx , and v , which is changed into $v - 1$, and not changed at all, in the first and second of these cases respectively.

(259.) We shall briefly observe, that the same sort of proof which shows that differential equations of the n th order are not completely integrated without the introduction of n arbitrary constants, has been applied to functional equations, as follows. If we suppose

$$\psi x = F_1(x, a_1, a_2, \dots, a_{n-1}), \quad \psi \alpha x = F_1(\alpha x, a_1, \dots)$$

$$\psi^2 x = F_2(x, a_1, a_2, \dots, a_{n-1}), \quad \psi \alpha x = F_2(\alpha x, a_1, \dots)$$

$$\dots \dots \dots$$

$$\psi^n x = F_n(x, a_1, a_2, \dots, a_{n-1}), \quad \psi \nu x = F_1(\nu x, \dots);$$

then the elimination of the $n - 1$ constants between each set of n equations gives an equation of the form $\Phi(x, \psi x, \psi^2 x, \dots, \psi^n x) = 0$, $\Phi(x, \alpha x, \dots, \nu x) = 0$, from which it is inferred that the complete solution of an equation of this form has at least $n - 1$ arbitrary constants. In the differential calculus the inference is so far just; but we have never been satisfied with any of the inverse inferences which have been made, to the effect that not more than $n - 1$ arbitrary constants could exist in the integral, though of course sufficiently sure by experience that the result, whether correctly inferred or not, is correct. Mr. Babbage* seems to have had a doubt on this subject on his mind, when he expresses himself upon "the train of reasoning usually made use of to prove that a differential equation of the n th order requires in its complete integral n arbitrary constants." And M. Lacroix, who has done as much for the differential calculus as Delambre did for astronomy, has not, in his researches, found even an attempt at a rigid demonstration. In speaking of what is, in fact, the same subject, namely, the various differential equations of the first order, which one of the n th implies, he uses these remarkable words: "*En s'abandonnant à l'analogie, on en conclura qu'une équation différentielle de l'ordre n a un nombre n d'intégrales premières.*"† We shall, therefore, not consider it an impertinent digression if we attempt to give what may be generalized into a proof of the proposition in question, in illustration of a remarkable point connected with functions.

(260.) In considering a function of x , y , and z , we must remark two distinct species. 1. Functions of x , y , and z , which cannot be reduced to the form $\phi(x, p)$

where p is a function of y and z . 2. Functions of x , and (y and z), which can be so reduced. Thus $y x^3 + z$ is an instance of the first sort; $x^3 + y z$ is an instance of the second. See (18.) and note. This precisely amounts to the distinction of the conditions under which, x only being variable, y and z are equivalent to two arbitrary constants, or to one only. The conditions of the second case are as follows. If $u = \phi(x, y, z)$, which can also be reduced to the form $\psi(x, p)$, then

$$\frac{du}{dz} \cdot \frac{dp}{dy} - \frac{du}{dy} \cdot \frac{dp}{dz} = 0,$$

which can easily be shown to be the necessary and sufficient condition, that u shall only contain x and y , because it is a function of p , or of some function of p . Now, if possible, let

$$\frac{du}{dx} = \chi(x, u) \text{ have the primitive } u = \phi(x, c, c_1);$$

the differentiation of the second gives

$$\frac{du}{dx} = \phi'(x, c, c_1) \quad c = \psi\left(x, \frac{du}{dx}, c_1\right).$$

The substitution of the form ψ for c in ϕ must eliminate c_1 ; for if not, we can express $\frac{du}{dx}$ in the form $\varpi(x, u, c_1)$, and therefore

$$\varpi(u, x, c_1) = \chi(x, u),$$

or the complete value of u can only contain c_1 , which is against the supposition. So that $\varpi(u, x, c_1)$ must be identical with $\chi(x, u)$, or otherwise a relation results which is not consistent with the supposition of u , containing two arbitrary constants. Consequently, $\phi(x, \psi, c_1)$ is independent of c_1 , or

$$\frac{d\phi}{d\psi} \cdot \frac{d\psi}{dc_1} + \frac{d\phi}{dc_1} = 0.$$

But from the identical equation

$$\phi'(x, \psi, c_1) - \frac{du}{dx} = 0 \text{ we get } \frac{d\phi'}{d\psi} \cdot \frac{d\psi}{dc_1} + \frac{d\phi'}{dc_1} = 0,$$

and from the two last we obtain

$$\left(\frac{d\phi}{d\psi} \cdot \frac{d\phi'}{dc_1} - \frac{d\phi}{dc_1} \cdot \frac{d\phi'}{d\psi}\right) \frac{d\psi}{dc_1} = 0.$$

Now, if $\frac{d\psi}{dc_1} = 0$, we have either $\frac{d\phi}{dc_1} = 0$, or $\frac{d\phi}{d\psi}$ is infinite for all values of ψ (a form of c); which last cannot be, and the first shows that ϕ is not a function of c_1 . But if

$$\frac{d\phi}{d\psi} \cdot \frac{d\phi'}{dc_1} - \frac{d\phi}{dc_1} \cdot \frac{d\phi'}{d\psi} = 0,$$

we see that ϕ can only be a function of ψ and c_1 , or of c and c_1 , in the form

$$u = \phi(x, \theta(c, c_1));$$

that is, the two arbitrary constants are equivalent only to one.*

* The (to us) apparent laxity of demonstration with which this subject is usually treated continues up to the present moment. M. Poisson, in the *Théorie de la Chaleur* just published, has a chapter on partial differential equations, in which the subject is treated with his usual happy combination of clearness and power. But he begins with a proof that the integral of a differential equation of the n th degree "*doit contenir, pour être complète, un nombre n de constantes arbitraires.*" This he does prove, with the exception of the proposition implied in the words *pour être complète*; for he does not show, or attempt to show, that no more than n arbitrary constants can be contained in the general integral.

† *Calc. Diff.* vol. ii. p. 294.

Calculus of Functions. (261.) The preceding process cannot be applied to equations of differences, and it is important to notice why this most simple case of functional equations differs so much, in general, from what may, in one point of view, be considered a particular case. In $\frac{dy}{dx}$ we are considering the properties of one term of a series; in $\frac{\Delta y}{\Delta x}$ we must consider the aggregate of all the terms.

If we let $\frac{\Delta a}{\Delta b} \Delta b$ stand for the difference of a , upon the supposition that b only varies, we do not find that

$$\frac{\Delta u}{\Delta y} \frac{\Delta \psi}{\Delta z} - \frac{\Delta u}{\Delta z} \cdot \frac{\Delta \psi}{\Delta y} = 0$$

is necessary when u is a function of x and $\theta(z, y)$. And it may be made evident that we can satisfy a functional equation by a solution containing as many arbitrary constants as we please. For instance,

$$\psi^2 x = x \text{ gives } \phi(1)^{\frac{1}{2}} \phi^{-1} x,$$

where ϕ may be a function which contains any number of arbitrary constants. To take a single instance, $(a-x)^{\frac{1}{2}}$, containing two arbitrary constants, satisfies $\psi^2 x = x$, the complete integral of which has been surmised to contain only one. But at the same time, remembering what we know relative to periodic functions, as opposed to all others, we cannot allow even a suspicion derived from them to affect our views of other functions.

The fact is, that in the most limited sense of the term, every functional equation admits of an infinite number of arbitrary constants, in admitting an arbitrary function. What we should ask in reference to the process in (259.) is this:—How many arbitrary constants can be found in such a manner as to admit of being converted into *separate arbitrary constants of the equation*, that is, arbitrary functions which remain constant during the verification of the equation? And, in this point of view, we cannot assign even so many arbitrary functions as might seem possible to the solution of $\psi^n x = x$, since we have found only one, and even given a method which shows all assignable solutions, at least, to be particular cases of that one.

(262.) We shall now proceed to the consideration of functions of more than one independent subject. If we take such a function as

$$\psi(x_1, x_2, x_3, \dots, x_{n-1}, x_n),$$

containing n independent subjects, we have n different ways of proceeding to what we might denote by ψ^2 ; or in a wider sense, we have

$$1 + n + n \cdot \frac{n-1}{2} + \dots + n \cdot \frac{n-1}{2} + n \text{ or } 2^n - 1$$

such methods. Thus, in the case of $\psi(x, y, z)$, which we shorten (where it is an ultimate form) into ψ , we have the following results of one repetition:

$$\begin{array}{lll} \psi(x, y, \psi) & \psi(x, \psi, \psi) & \\ \psi(x, \psi, z) & \psi(\psi, y, \psi) & \psi(\psi, \psi, \psi) \\ \psi(\psi, y, z) & \psi(\psi, \psi, z) & \end{array}$$

(263.) Before we proceed with this subject, it is necessary to remark, that the preceding operations contain more *indeterminateness*, if we may use the phrase, in proportion to those already considered, than we should

suppose by comparing $x+y$ and x , which is such an analogy as would naturally present itself. In fact, we are not proceeding from the consideration of x to that of $x+y$ where $+$ is defined, but to $x+y$ where $+$ may represent any operation whatever. But we should first consider cases in which the method in which x and y enter the function is of imperfect generality; for instance, such as

$$\psi\{\alpha(x, y)\}, \quad \psi(x+y), \quad \psi(axy-y^2), \text{ \&c.,}$$

in which x and y enter through a given function.

Again, the successive functions arising out of the preceding method may subject x and y to new operations at every step, that is, to operations not performed upon them in the original function. This cannot happen in functions of a single subject. If we see $\sin x$ in the tenth function, it must have been in the first. We may avoid this by allowing only what we will call *lineal* substitution, that is, not regarding any letter as a variable, except it come from itself in the original function. This may be best done as follows: instead of substituting $\psi(x, y)$ for x , and thus introducing y under all the signs of operation to which x is subject, give a specific value b to y before substitution. If, for the present, we denote by $\psi_y \psi$ and $\psi_x \psi$, the results of one substitution of this kind, in the first of which x becomes a before substitution for y , and in the second of which y becomes b before substitution for x , we find

$$\psi_y \psi_x \psi = \psi_x \psi_y \psi = \psi(\phi \overline{x}, b, \psi \overline{a}, y),$$

whence it follows that $\psi_x \psi_y \psi_x \psi = \psi_x^2 \psi_y \psi = \psi_y \psi_x^2 \psi$; or, generally, $\psi_x^m \psi_y^n \psi = \psi_y^n \psi_x^m \psi$.

To avoid proposing different classes of notation for different species of substitution, which we shall not have much occasion to employ together, we shall denote lineal substitutions simply by affixing the equations of condition which determine the specific values of x and y . Thus, by

$$\psi_{\substack{x=a \\ y=b}}^{m, n}(x, y) \text{ or } \psi^{m, n}(x, y) \left[\substack{x=a \\ y=b} \right],$$

we mean that m lineal substitutions of $\psi(x, b)$ for x and n substitutions of $\psi(a, y)$ for y have taken place. If, when the process is finished, we restore x and y instead of a and b , we may write

$$\psi_{\substack{x=a \\ y=b}}^{m, n}(x, y) \text{ or } \psi^{m, n}(x, y) \left[\substack{x=a \\ y=b} \right];$$

and if we finally write a and b instead of x and y , we may signify the result by

$$\psi_{\substack{x=a \\ y=b}}^{m, n}(a, b) \text{ or } \psi^{m, n}(a, b) \left(\substack{x=a \\ y=b} \right).$$

(264.) General substitution is that explained in (262.), and the immediate consequence of the distinction between it and lineal substitution is, that the order of the operations is not indifferent. Mr. Babbage has proposed the following notation,*

$$\psi_{1 \ 2 \ 3 \ 4 \ 5}^{m_1 \ m_2 \ m_3 \ m_4 \ m_5}(x, y, z),$$

to denote that 1. the m th function of the preceding is taken relatively to the letter written first, namely x ; 2. the result is considered as a function of z , (the third letter,) and its n th function taken on that supposition; 3. the p th function of the result is taken relatively to y ; 4. the q th function of the result relative to x ; 5. the r th function of the result relative to y . By the symbol

* About the same time M. Cauchy proposed an analogous method of representing interchanges. *Journ. Ec. Polytech. Cah.* 17, 1815.

Calculus of
Functions.

$$\psi^{m,m,m}(x,y,z)$$

we understand m general simultaneous substitutions, that is, we write $\psi(x,y,z)$ at once instead of both x,y , and z . Thus

$$\psi^{3,3}(x,y) = \psi(\psi(\psi(x,y), \psi(x,y)), \psi(\psi(x,y), \psi(x,y))).$$

(265.) It is much more easy to invent notation for cases which it may be conceived will hereafter arise, than to enter into the general solution of any one instance. The following extract* will show both the excessive complication of the questions which might be proposed, and the difficulty of taking in at one view the conditions of the problem.

$$\psi^{2,3,2,2,2,2,2,2,2,2}(x,y,z,v) = f x \frac{z}{\beta x} z = \gamma x \}.$$

The equation contains the analytical enunciation of the following problem. What must be the form of a function of four quantities $\psi(x,y,z,v)$, such that taking the second function relative to z , the third relative to x , and the second simultaneous one relative to z and v ; if, in the result, αx be put for y and βz for v , and the whole be then considered as a function of x and z ; and if, on this hypothesis, the third function be taken relative to z , and the second relative to x ; and, if γx be now put for z , and the third function of the expression considered merely as a function of x be taken, then it is required that the final result shall be equal to $f x$, a given function of x ?

We shall now proceed to the consideration of some cases of functions of more subjects than one.

(266.) So long as we consider substitution relative to one subject only, it is evident that we do not take a more general case than those which have been considered in the former part of this Treatise; thus we have

$$\psi^{n,1}(x,y) = \alpha^n x \text{ where } \psi(x,y) = \alpha x$$

$$\psi^{1,n}(x,y) = \beta^n y \text{ where } \psi(x,y) = \beta y$$

$$\psi^{0,1}(x,y) = x \quad \psi^{1,0}(x,y) = y.$$

In these cases one subject only is considered as variable, and the other may be treated as an arbitrary constant. In a similar manner, we have

$$\psi^{0,m}(x,y) = x \quad \psi^{m,0}(x,y) = y;$$

for since $\psi^{0,1}(x,y)$ is not a function of y , the successive functions of it with respect to y are the same in value as the first function. We must remember, that though by definition $\psi^{1,1}(x,y)$ and $\psi^{1,1}(x,y)$ are the same, being, in fact, only the same function considered as a basis for two different kinds of substitutions; yet, since $\psi^{m,n}(x,y)$ has two different values according as the substitutions are made first relative to x and then to y , or *vice versa*, the function $\psi^{0,0}(x,y)$ may be either $\psi_{1,2}^{0,0}(x,y)$ or $\psi_{2,1}^{0,0}(x,y)$. The first, as a particular case of $\psi^{0,m}(x,y)$, is x ; the second, for a similar reason, is y .

(267.) By the definition of simultaneous substitution, we have the following equation,

$$\psi^{m,m}(\psi x, y, \psi x, y) = \psi^{m+1, m+1}(x, y) \dots (A),$$

for all whole values of m from 1 upwards. We shall also readily find that the preceding order is invertible, as follows:

$$\psi\{\psi^{m,m}(x,y), \psi^{m,m}(x,y)\} = \psi^{m+1, m+1}(x,y) \dots (B).$$

* Babbage, *Essay, &c.*, part ii. *Phil. Trans.* 1816.

For if we consider the various manners in which ψ enters into $\psi^{3,3}$, for instance, as follows:

$\overline{1, 1}$	$\overline{2, 2}$	$\overline{3, 3}$
ψ	ψ	ψ
	ψ	ψ
		ψ

And if we next consider $\psi^{4,4}$ as derived from substituting ψ for both x and y in the preceding, we have the following expression, without brackets:

$$\left\{ \begin{array}{ccc} & \psi & \psi \\ \psi & & \psi \\ & \psi & \psi \\ \psi & & \psi \\ & \psi & \psi \\ \psi & & \psi \end{array} \right\}$$

which, after the brackets are written, appears exactly the same as substituting $\psi^{3,3}$ for x and y in $\psi x, y$. If, then, we make $m = 0$ in (A) and (B), in like manner as we hitherto have applied extended notation only to cases which satisfy such conditions of convertibility as are satisfied by the general notation, we must make the following equations determine $\psi^{0,0}$, namely,

$$\psi^{0,0}\{\psi(x,y), \psi(x,y)\} = \psi(x,y) \dots (A)$$

$$\psi\{\psi^{0,0}(x,y), \psi^{0,0}(x,y)\} = \psi(x,y) \dots (B)$$

and we are thus led to a condition which we shall consider as analogous to convertibility, and shall denominate *simultaneous convertibility*, namely,

$$\beta(\alpha x, y, \alpha x, y) = \alpha(\beta x, y, \beta x, y).$$

(268.) But there may be functions which satisfy one of the preceding equations, but not the other, analogous in species to the inconvertible inverses already considered.

For example, if $\psi(x,y) = x + y$, we find that

$$\psi^{0,0}(x,y) = \frac{1}{2}x + \frac{1}{2}y \text{ satisfies both equations, while}$$

$\psi^{0,0}(x,y) = x$ satisfies the first only, as does $\psi^{0,0}(x,y) = y$. In analogy with $\phi^0 \phi x = \phi \phi^0 x = x$, which do not involve a condition, because $\phi^0 x$ or x is convertible with all

functions, we shall let $\psi^{0,0}$ signify those functions only in which both equations are satisfied; while those which satisfy the first only shall be denoted by $\psi_{0,0}^{0,0}$; those which satisfy the second only belong to an infinite undefined class, presenting analogies with the functions we have denoted by the letter ξ , and point out an analogy which has not struck us till this moment. The equation $\phi \phi^0 x = \phi x$ being satisfied by $\phi^0 x = x$ is also satisfied by every form of $\xi \phi^0 x$. Agreeably to the character of the notation we have hitherto employed, $\phi^0 x$ should be the symbol of αx in the equation $\phi \phi^0 x = \phi x$, or in $\xi \alpha x = \xi x$ αx is $\xi_0 x$.

(269.) The functions which satisfy the first equation only are infinite in number, and (which is a further analogy with $\phi^0 x$ in $\phi \phi^0 x = \phi x$) independent of the form of $\psi(x,y)$. For equation (A) simply gives

$$\psi^{0,0}(a,a) = a.$$

Thus $m x - n y$ or $x^m y^{-n}$, (where $m - n = 1$); $x \alpha \left(\frac{y}{x}\right)$.

Calculus of
Functions.

where $\alpha(1) = 1$; $\cos \left\{ \frac{y}{x} \cos^{-1} x \alpha \left(\frac{y}{x} \right) \right\}$, &c. &c. are all general forms of $\psi_{0,0}(x, y)$.

And it must be observed, that whenever the second equation is satisfied, the first is satisfied by one or other of the values of $\psi_{0,0}$ derived from it. For, if we determine a from the equation

$$\psi(a, a) = \psi(x, y),$$

and if we afterwards make $x = y$, it is evident that one value of a reduces itself to x .

For example, given

$$\psi(x, y) = x^2 + y, \text{ required } \psi_{0,0}(x, y);$$

$$a^2 + a = x^2 + y \text{ gives } a = -\frac{1}{2} \pm \sqrt{\frac{1}{4} + x^2 + y},$$

and the positive sign gives the function required, for

$$\sqrt{x^2 + x + \frac{1}{4}} - \frac{1}{2} = x.$$

Given $\psi(x, y) = \sin(xy)$, required $\psi_{0,0}(x, y)$; this gives $\psi_{0,0}(x, y) = \sqrt{xy}$.

(270.) If we call $\psi_{0,0}$ the zero-function* of ψ , we have the following theorems.

1. The zero-function of $\alpha(x, y)$ is also a zero-function of $\psi\alpha(x, y)$, ψ being any form whatever of a single subject. For the equation $\alpha(a, a) = \alpha(x, y)$ gives $\psi\alpha(a, a) = \psi\alpha(x, y)$, and $\alpha_{0,0}(a, a) = a$ gives

$$\alpha_{0,0}(\psi\alpha x, y, \psi\alpha x, y) = \psi\alpha x, y;$$

so that

$$(\psi\alpha)_{0,0}(x, y) = \alpha_{0,0}(x, y).$$

2. The zero-function of a zero-function is the zero-function itself; for if $\chi(a, a) = a$, which is the sufficient characteristic of χ being the zero-function of some function or other, we see that $\chi(a, a) = \chi(x, y)$ gives $a = \chi(x, y)$.

We are thus led back again to the remark already made relative to the step from ψx to $\psi(x, y)$ being too great a generalization. The consideration of $\psi\alpha(x, y)$, for the various given forms of α , divides all functions of two subjects into a number of classes, the zero-function of all the individuals of a class being the same. And we shall denote by the name of *primitive zero-functions* all those which have no other zero-function except themselves; that is, all functions of the form $\chi(x, y)$ which satisfy the equation $\chi(x, x) = x$.

The same notions may be extended to functions of three, or any number of subjects. The zero-functions of sums and products are sufficiently known under the names of *means* and *mean proportionals*.

Every function $\phi(x, y)$ can be represented under the form $\Phi\phi_0(x, y)$, where ϕ_0 means the zero-function of ϕ , and is one of the primitive zero-functions contained in the general solution of $\phi(x, x) = x$.

(271.) No zero-function can be a function of any other zero-function as a single subject, that is, *all zero-functions are primitives*, and we may therefore drop the latter term. For if $\phi(x, x) = x$, and $\psi(x, x) = x$, and if $\phi(x, y) = \alpha\psi(x, y)$, we have, making $y = x$,

$$x = \alpha x, \text{ or } \phi(x, y) = \psi(x, y).$$

But any zero-function of two or more zero-functions

* The simultaneous zero-function, if distinction be required.

is also a zero-function, as is sufficiently evident: and any zero-function may be expressed in terms of any other, together with one of the functions presently to be discussed, in which $f(x, x) = 0$.

If, for example,

$$\alpha^0 = \beta^0 + P,$$

P must be reduced to zero by $y = x$.

(272.) Let $\psi(x, y)$ be a function such that $\psi(x, a) = x$; then if $\chi(x, y)$ be any zero-function, the following contains an extensive class of the same kind,

$$\chi\left(x, \psi\left\{x, a \alpha\left(\frac{y}{x}\right)\right\}\right), \alpha(1) = 1;$$

and thus, by successive substitution, we may show that no form exists under which all zero-functions can be shown with any finite number of arbitrary functions.

But the most obvious form of all zero-functions is

$$x + \theta(x - y)\psi(x, y),$$

where $\theta(0) = 0$ and $\psi(x, x)$ is not infinite.

(273.) Homogeneous functions are reduced by making $x = y$ to the form ax^n , where n is the dimension of the function. The form being

$$\psi(x, y) = ax^n \alpha\left(\frac{y}{x}\right), \alpha(1) = 1;$$

we have

$$\psi_{0,0}(x, y) = x \sqrt[n]{\alpha\left(\frac{y}{x}\right)}.$$

(274.) If the function $\psi(x, y)$ be of such a kind that $\psi(x, x) = \text{constant}$, including 0 or ∞ under the general term constant, the preceding method fails, since we cannot discover a real function of a to equate with $\psi(x, y)$. But in this case it must be observed, that we have the equation

$$\psi_{m,m}(x, y) = \text{constant},$$

independently of m . We shall presently see that we shall be obliged to consider the corresponding zero-functions

as *infinite*, or at least of the form $\omega\left(\frac{1}{0}\right)$. Thus in $\alpha x - \alpha y$

we see a class of functions which satisfy the equation $\psi_{0,0}(x, y) = \omega\left(\frac{1}{0}\right)$. But the original function cannot

be derived from the zero-function in this case, by either of the equations (A) or (B), nor can two functions which have the same zero-functions be made functions of each other. Thus we cannot make $x^2 - y^2$ a function of $x - y$, though both have the zero-function ∞ . Those functions which have infinite zero-functions present analogies in some respect with the constant of the differential calculus, and also with the absolute zero of Algebra. For instance, if $\chi(x, y)$ represent a function which has an infinite zero-function (that is, which gives $\chi(x, x) = 0$); then $\psi(x, y) + \chi(x, y)$ has the same zero-function as $\psi(x, y)$, after $\psi + \chi$ has been substituted instead of ψ : thus the zero-function of xy being $\sqrt{xy}$, that of $xy + x - y$ is $\sqrt{xy + x - y}$. Again, $\chi(x, y) \times \psi(x, y)$ is another form of $\chi(x, y)$, if $\psi(x, x)$ be finite. It is, moreover, evident that

$$\alpha(\phi(x, y), \phi_0(x, y))$$

has the zero-function $\phi_0(x, y)$ the same as that of $\phi(x, y)$. And many other theorems might be deduced, all conveying certain ideas of classification among functions of two

Calculus of
Functions.

Calculus of Functions.

or more variables, and by means of which the every-day algebraical properties of simple functions may be made the guides to generalization.

"Any zero-function" is the answer to the following question:—What is the value of z in terms of x and y , which shall give

$$1 = \frac{dz}{dx} + \frac{dz}{dy} \text{ (when } y = x \text{)}$$

$$\text{or } 0 = \frac{d^2 z}{dx^2} + 2 \frac{d^2 z}{dx \cdot dy} + \frac{d^2 z}{dy^2} \text{ \&c. \&c. ?}$$

For a given value of $\frac{dz}{dy}$, there is one zero function, namely,

$$\psi(x, y) - \psi(x, x) + x,$$

where

$$\psi(x, y) = \int \frac{dz}{dy} \cdot dy.$$

(275.) By the *modulus* of $\alpha(x, y)$ we mean the function $\alpha(x, x)$ considered as of a single subject. The moduli of the sum, difference, product, &c. of two functions are the sum, difference, &c. of the moduli. And the modulus of $\frac{dz}{dx} + \frac{dz}{dy}$, where z is a function of x and y , is the differential coefficient of the modulus of z . For if we put the zero-function in the form

$$\alpha^{0,0}(x, y) = \frac{x+y}{2} + \psi(x-y)\chi(x, y), \quad \psi(0) = 0,$$

and if we denote the modulus of $\alpha(x, y)$ by $\bar{\alpha}x$, we have

$$z = \bar{\alpha} \alpha^{0,0}(x, y),$$

$$\frac{dz}{dx} = (\bar{\alpha}' \alpha^{0,0}) \left(\frac{1}{2} + \psi'(x-y)\chi(x, y) - \psi(x-y) \frac{d\chi}{dx} \right),$$

or

$$\left(\frac{dz}{dx} \right) = \bar{\alpha}' x \left(\frac{1}{2} + \psi' 0 \cdot \chi x \right);$$

similarly,

$$\left(\frac{dz}{dy} \right) = \bar{\alpha}' x \left(\frac{1}{2} - \psi' 0 \bar{\chi} x \right),$$

whence

$$\left(\frac{dz}{dx} + \frac{dz}{dy} \right) = \bar{\alpha}' x.$$

Similarly we find the modulus of

$$\beta(x, y) \frac{dz}{dx} + \beta(y, x) \frac{dz}{dy} \text{ to be } \bar{\beta} x \bar{\alpha}' x,$$

of which the well-known theorem relative to the value of $x \frac{dz}{dx} + y \frac{dz}{dy}$ in homogeneous functions will give a particular case.

(276.) If we consider a function which has a numerator and denominator with zero for the moduli of both, having the form

$$\frac{\psi(x-y)\chi(x, y)}{\psi_1(x-y)\chi_1(x, y)} \quad \psi 0 = 0, \chi 0 = 0,$$

we find its modulus to be $\frac{0}{0}$, which is in this case

$$\frac{\psi' 0 \chi x}{\psi'_1 0 \chi_1 x}$$

(277.) Sir J. Herschel* has applied equations of differences to the determination of functions, which satisfy certain conditions when y is made a given function of x . We give one instance of this method, as follows.

Suppose it required to solve

$$\psi(x, x) - \psi(x, 0) = a.$$

Let there be a function of x and y , which becomes $f(x, h)$ when $y = 0$ and $f(x, h+1)$ when $y = x$.

Such a function is $f(x, h+P)$, where $x = 0$ makes $P = 0$ and $x = y$ makes $P = 1$. Assume $\psi(x, y) = f(x, h+P)$, which gives

$$f(x, h+1) - f(x, h) = Q;$$

and this gives

$$f(x, h) = ah + Q,$$

where Q is any function which is the same whether 0 or x be substituted for y . This equation being identically satisfied for all values of h , write $h+P$ for h , and we have

$$\psi(x, y) = a(h+P) + Q.$$

The general form of Q is

$$\alpha x + \psi x \cdot \psi_1(y-x)\chi(x, y),$$

where $\psi 0 = 0, \psi_1 0 = 0$. And the form of P is

$$\beta \frac{x}{y} + \omega x \omega_1(y-x)\chi_1(x, y),$$

where $\beta 0 = 0, \beta 1 = 1, \omega 0 = 0, \omega_1 0 = 0$. Whence the general form, supposing ah included in αx , is

$$\alpha x + a\beta \frac{x}{y} + \theta x \theta_1(x-y)\Theta(x, y),$$

where

$$\theta 0 = 0 \quad \theta_1 0 = 0.$$

(278.) *Simultaneous derivation*† is the formation of such functions as $\phi \alpha(\phi^{-1}x, \phi^{-1}y)$ from $\alpha(x, y)$, and it will be found that these derivatives possess the properties already treated in speaking of functions of one subject. When we wish to consider a derivative or other compound function as a simple function of x and y , we shall write it in [] brackets, which shall be reserved for this purpose only, and the exponents of operation relatively to the whole may be written on the outside.

(A) Derivatives of derivatives of $\alpha(x, y)$ are derivatives of $\alpha(x, y)$.

(B) If $\mu(x, y)$ and $\nu(x, y)$ be corresponding derivatives (derived by means of the same function ϕ) of $\alpha(x, y)$ and $\beta(x, y)$, then $\mu\{\nu(x, y), \nu(x, y)\}$ is the corresponding derivative of $\alpha\{\beta(x, y), \beta(x, y)\}$.

(C) If α and β have the corresponding derivatives μ and ν , and if $\alpha(\beta, \beta) = \beta(\alpha, \alpha)$, then $\mu(\nu, \nu) = \nu(\mu, \mu)$.

(D)† The successive functions, however taken, of any derivative of $\alpha(x, y)$, are the corresponding derivative of the same successive functions of α . Suppose it true for any one derivative of $\alpha(x, y)$, and any one value of $\frac{m}{1}, \frac{n}{2}$, that

$$[\phi \alpha(\phi^{-1}x, \phi^{-1}y)]^{\frac{m}{1}, \frac{n}{2}} = \phi \alpha^{\frac{m}{1}, \frac{n}{2}}(\phi^{-1}x, \phi^{-1}y),$$

then a substitution such as changes n into $n+1$ on the first side, actually made in the second side, gives

$$\phi \alpha^{\frac{m}{1}, \frac{n}{2}}(\phi^{-1}x, \alpha(\phi^{-1}x, \phi^{-1}y));$$

but if we now take $\alpha^{\frac{m}{1}, \frac{n}{2}}$ and change n into $n+1$ before derivation, we find

Calculus of
Functions.

$$\alpha^{m, n+1}(x, y) = \alpha^{m, n}(x, \alpha(x, y)),$$

whence the theorem readily follows by the usual method of successive induction. Let P be the symbol of

$$m, m', m'', \dots$$

$$n, n', n'', \dots$$

where $n, n', \dots$ are severally either 1 or 2, and we have

$$[\phi \alpha(\phi^{-1}x, \phi^{-1}y)]^P = \phi \alpha^P(\phi^{-1}x, \phi^{-1}y).$$

(279.) All the derivatives of zero-functions are zero-functions. For if $\alpha(x, x) = x$, we have $\phi \alpha(\phi^{-1}x, \phi^{-1}x) = \phi \phi^{-1}x = x$, or $\phi \alpha(\phi^{-1}x, \phi^{-1}y)$ is a zero-function. And if $\psi_0(x, y)$ be the zero-function of $\psi(x, y)$, then $\phi \psi_0(\phi^{-1}x, \phi^{-1}y)$ is the zero-function of $\chi \phi \psi(\phi^{-1}x, \phi^{-1}y)$. Similarly if $\alpha(x, x) = \text{constant}$, the derivatives of $\alpha(x, y)$ have the same property.

(280.) If any function be *simultaneously periodic*, then all its derivatives are the same. Or if

$$\alpha^{m, m}(x, y) = \alpha^{0, 0}(x, y),$$

then

$$\begin{aligned} \phi \alpha^{m, m}(\phi^{-1}x, \phi^{-1}y) &= \phi \alpha^{0, 0}(\phi^{-1}x, \phi^{-1}y) \\ &= [\phi \alpha(\phi^{-1}x, \phi^{-1}y)]^{0, 0} \end{aligned}$$

It remains to inquire what are the various classes of simultaneously periodic functions.

Firstly, all zero-functions themselves are what we may call permanent; for if $\chi(x, x) = x$, we have

$$\chi^{2, 2}(x, y) = \chi(\chi(x, y), \chi(x, y)) = \chi(x, y),$$

and, generally,

$$\chi^{n, n}(x, y) = \chi(x, y) = \chi^{0, 0}(x, y).$$

To obtain functions which are not permanent, but periodic, and of one certain degree, take any periodic function of a single subject, of the order required, and substitute instead of the subject a zero-function of x and y . That is, let $\phi^n x = x$, and $\alpha(x, x) = x$, then $\phi \alpha(x, y)$ is simultaneously periodic. For we have

$$(\phi \alpha)^{2, 2}(x, y) = \phi \alpha(\phi \alpha x, \phi \alpha y) = \phi^2 \alpha(x, y),$$

or, generally,

$$\begin{aligned} \phi \alpha^{m, m}(x, y) &= \phi^m \alpha(x, y) \\ &= \alpha(x, y) = \alpha^{0, 0}(x, y) = (\phi \alpha)^{0, 0}(x, y). \end{aligned}$$

Thus, if we take the zero-function $\frac{1}{2}(x + y)$, and the periodic function of it of the second degree $\frac{2}{x + y}$, we find

$$\alpha^{2, 2}(x, y) = \frac{2(x + y)}{2 + 2} = \frac{x + y}{2} = \alpha^{0, 0}(x, y).$$

(281.) The easiest mode of actually exhibiting the simultaneous functions of $\alpha(x, y)$ consists in writing it in the form $A \alpha^{0, 0}(x, y)$, where $\alpha^{0, 0}$ is z in the equation $\alpha(z, z) = \alpha(x, y)$. For we then have

$$\begin{aligned} \alpha^{2, 2}(x, y) &= A \alpha^{0, 0} \{A \alpha^{0, 0}(x, y), A \alpha^{0, 0}(x, y)\} \\ &= A A \alpha^{0, 0}(x, y) = A^2 \alpha^{0, 0}(x, y), \end{aligned}$$

and, generally,

$$\alpha^{m, m}(x, y) = A^m \alpha^{0, 0}(x, y).$$

In perfect analogy with functions of one subject, we should call $\alpha^{0, 0}$ the subject, and A the functional symbol: but the necessity of considering $\alpha^{0, 0}$ separately as a function of two subjects will oblige us to relinquish this

method of expression. We have called A the *modulus** of the function $\alpha(x, y)$. Consequently, we can immediately assign the simultaneous functions of a very large class of complicated functional forms, the essentials being that $\alpha(z, z) = \alpha(x, y)$ shall be capable of solution, and that $\alpha(z, z)$ shall also be of one of the forms whose n th functions (considered as functions of a single subject) shall be attainable in finite terms. Thus in the case of

$$\alpha(x, y) = \frac{x + y \log \left(\frac{x}{y} \right)}{x^2 + xy + y^2}$$

$$\alpha^{0, 0}(x, y) = 3\alpha(x, y), \quad Az = \frac{z}{3}$$

$$\alpha^{n, n}(x, y) = \frac{1}{3^n} \cdot \frac{x^3 + y^3 \log \left(\frac{x}{y} \right)}{x^2 + xy + y^2}.$$

(282.) Since every function can be reduced to the form $A \alpha^{0, 0}(x, y)$, a change of a constant or other change which reduces $\alpha(x, x)$ to zero, or Ax to zero, will at the same time reduce $\alpha^{0, 0}$ in $A \alpha^{0, 0}$ to a function of α . Thus, if we take $\omega x - m \omega y$, the zero-function of which is

$$\omega^{-1} \left(\frac{\omega x - m \omega y}{1 - m} \right), \quad \text{and } Az = \omega z(1 - m),$$

the supposition of $m = 1$ reduces Az to zero, and $\alpha^{0, 0}(x, y)$ to $\omega^{-1} \left(\frac{\omega x}{0} \right)$, which is constant, nothing, or

infinite. In the case of $x - ay$, we have $\alpha^{0, 0} = \alpha$

The addition of a constant makes no difference in the zero-function, but only in the modulus, to which it adds a constant.

(283.) Since $\phi(\alpha x, \alpha y) = \bar{\phi} \alpha \alpha^{-1} \phi^{0, 0}(\alpha x, \alpha y)$, and the modulus of this function is $\bar{\phi} \alpha$, its zero-function is $\alpha^{-1} \phi^{0, 0}(\alpha x, \alpha y)$, or we see that $\alpha^{-1} \phi^{0, 0}(\alpha x, \alpha y)$ is the zero-function of $\phi(\alpha x, \alpha y)$.

It is almost needless to say, that if two functions be identically the same, their zero-functions and moduli must be the same.

(284.) If β be a derivative of α , then both the modulus and zero-function of β are the corresponding derivatives of those of α . For let

$$\beta(x, y) = B \beta^{0, 0}(x, y) \quad \alpha(x, y) = A \alpha^{0, 0}(x, y),$$

and

$$B \beta^{0, 0}(x, y) = \phi A \alpha^{0, 0}(\phi^{-1}x, \phi^{-1}y),$$

if we make $x = y$, we find $Bx = \phi A \phi^{-1}x$; and, therefore,

$$\phi A \phi^{-1} \beta^{0, 0}(x, y) = \phi A \alpha^{0, 0}(\phi^{-1}x, \phi^{-1}y),$$

which is ratified by

$$\beta^{0, 0}(x, y) = \phi \alpha^{0, 0}(\phi^{-1}x, \phi^{-1}y).$$

It is evident, therefore, that the problem of making any function β a derivative of any other function α cannot be generally solved. First make the modulus of one a derivative of the modulus of the other; then see

* Such terms as *modulus*, *derivative*, &c. have been purposely used, because, from the various senses in which they have been used, they are *movable* terms. They must not be considered as of permanent application.

Calculus of
Functions.

Calculus of Functions. whether the deriving function so obtained will make the zero-function of one the derivative of that of the other.

We shall apply the process in (50.) to this problem.

If we consider $\alpha^{n,n}$ and $\beta^{n,n}$ as functions of n , and $\alpha^{0,0}$ and $\beta^{0,0}$ respectively, and eliminate n between the two equations,

$$A^n \alpha^{0,0}(x, y) = c \quad B^n \beta^{0,0}(x', y') = c',$$

we find an equation of the following for

$$\beta^{0,0}(x', y') = \varpi \alpha^{0,0}(x, y),$$

where ϖ is evidently the deriving function of B from A . This equation, by the method of obtaining it already explained, remains true if we substitute $\alpha(x, y)$ for x and y , and $\beta(x', y')$ for x' and y' : that is,

$$\beta(x', y') = \varpi \alpha(x, y) \dots \beta^{m,m}(x', y') = \varpi \alpha^{m,m}(x, y)$$

are all consequences of the first. The condition under which β may then be a derivative of α is the permanence of the first of these equations, when ϖx and ϖy are substituted for x' and y' . Let us suppose

$$\alpha(x, y) = ax + by \quad \beta(x', y') = \sqrt{ax'^2 + by'^2}$$

$$\alpha^{n,n}(x, y) = (a + b)^{n-1} (ax + by)$$

$$\beta^{n,n}(x', y') = (a + b)^{\frac{n-1}{2}} \sqrt{ax'^2 + by'^2},$$

and

$$ax'^2 + by'^2 = ax + by$$

is the equation which results from equating the preceding to unity, and eliminating n . This gives between the zero-functions the equation

$$\beta^{0,0}(x, y) \text{ or } \sqrt{\frac{ax'^2 + by'^2}{a+b}} = \sqrt{\frac{ax + by}{a+b}} \text{ or } \sqrt{\alpha^{0,0}(x, y)};$$

so that $\varpi z = \sqrt{z}$. Substitute $\sqrt{x}$ for x' and $\sqrt{y}$ for y' , and the equation becomes identically true. Hence the first is a derivative of the second, as is indeed sufficiently evident.

(285.) It remains to inquire whether any given zero-function can be made a derivative of any other. It does not appear that this can be generally done, as in the case of functions of a single subject. For instance, all the derivatives of symmetrical functions are symmetrical. And on comparing the question in the following manner with the corresponding question as to a single subject (which will often be found useful in tracing analogies) we see a material limitation introduced. The equation

$$\beta(x, y) = \phi \alpha(\phi^{-1}x, \phi^{-1}y)$$

is evidently a particular case of the derivation of $\beta(x, y)$ from $\alpha(x, y')$, considered as functions of one subject only, and y and y' being independent arbitrary constants. The deriving function ϕx , being thus obtained, must now be further subjected to the condition $y' = \phi^{-1}y$, which it may be impossible to satisfy. But the following method will show that (continuously or discontinuously) a zero-function may, in some cases, be made a derivative of another. Let $\alpha(x, y)$ and $\beta(x, y)$ be two zero-functions, and assume the equations

$$\beta(x', y') = c' \quad \alpha(x, y) = c,$$

which, by the permanence of zero-functions under simultaneous substitutions, admit of $\beta(x', y')$ and $\alpha(x, y)$ being substituted for x' and y' and for x and y . From these deduce

$$y' = Bx' \quad y = Ax$$

and assume $y' = \gamma y$. We have thus, by substitutions shown to be legitimate,

$$\beta(x', y') = B\beta(x', y'), \quad \alpha(x, y) = A\alpha(x, y)$$

$$Bx' = \gamma Ax, \quad B\beta(x', y') = \gamma A\alpha(x, y);$$

or

$$\beta(B^{-1}\gamma Ax, \gamma y) = B^{-1}\gamma A\alpha(x, y),$$

which are necessary consequences of the first two equations and true for all forms of γ . To obtain β as a derivative of α , we have only to assume

$$B^{-1}\gamma Ax = \gamma x, \text{ or } Bx = \gamma A\gamma^{-1}x,$$

or the function by which one zero-function β is derived from another α , is the same as that by which the value of y' in $\beta(x', y') = c'$ is derived from the value of y in $\alpha(x, y) = c$. It thus appears why symmetrical functions can only be derived continuously from each other: for if $\beta(x, y)$ be a symmetrical function of x and y , the equation $\beta(x, y) = c$ shows y to be a periodic function of x of the second degree; thus, if $\beta(x, \phi x) = c$, and if $\beta(\phi x, x) = \beta(x, \phi x)$, the substitution of $\phi^{-1}x$ for x in the first gives $\beta(\phi^{-1}x, x) = c = \beta(\phi x, x)$, one solution of which is $\phi x = \phi^{-1}x$ or $\phi^2 x = x$.

But in the preceding solution it must be remembered that the initial suppositions

$$\beta(x' y') = c' \quad \alpha(x, y) = c$$

remain in force, restricting the truth of the derivation to such values of x and y as simultaneously satisfy these relations. The derivation can only be general in such cases as give values of γx , which, by the process, are independent of c and c' , or in which c and c' are otherwise removed from the final equation. In the case where neither zero-function is symmetrical, two new arbitrary constants are introduced in the derivation of B from A , by means of particular values of which it may happen that the constants c and c' do not appear in γx . In the case where both are symmetrical, there is an infinite number of ways in which B may be derived from A (75.), and any number of arbitrary constants may be introduced.

For instance, suppose it required to derive $\sqrt{xy}$ from $\frac{x+y}{2}$. Here we have

$$\alpha(x, y) = \frac{x+y}{2} \quad \beta(x', y') = \sqrt{x'y'} \quad Ax = 2c - x \quad Bx' = \frac{c'^2}{x'}.$$

One value of γx is

$$\frac{c'(2c - x)}{x} \text{ or } \gamma^{-1}x = \frac{2cc'}{x + c'}$$

giving

$$\gamma(2c - \gamma^{-1}x) = \frac{c'^2}{x}.$$

But

$$\gamma \alpha(\gamma^{-1}x, \gamma^{-1}y) = \frac{2xy + (x+y)c'}{2c' + x + y},$$

which is $= \sqrt{xy}$, when $xy = c'^2$ and $x + y = 2c$

But if we choose $\gamma x = e^{mx}$, giving

$$\gamma(2c - \gamma^{-1}x) = \frac{e^{2cm}}{x},$$

we find that $\frac{c'^2}{x}$ is thus made a derivative of x , if

$e^m = c'^{\frac{1}{c}}$, and we find that in this case $\sqrt{xy}$ is a derivative of $\frac{x+y}{2}$; for if

Calculus of
Functions.

$$\gamma x = c^{\frac{x}{c}} \quad \gamma^{-1} x = c^{\frac{\lambda x}{\lambda c'}}$$

$$\sqrt{xy} = \varepsilon^{\frac{\lambda x + \lambda y}{2}} = c^{\frac{1}{2c}} \left(c^{\frac{\lambda x}{\lambda c'}} + c^{\frac{\lambda y}{\lambda c'}} \right).$$

The question, therefore, whether any one zero-function can be made a derivative of any other remains unsettled; for in the preceding process there are two places certainly, and two more possibly, in which the present state of analysis requires the substitution of constants instead of arbitrary functions, the former in deriving B from A, the latter in the constants c and c' . For it is sufficient that c and c' should be functions which do not change when $\alpha(x, y)$ and $\beta(x', y')$ are severally substituted for x and y and for x' and y' . The only forms of such functions known to us are $\theta \alpha(x, y)$ and $\theta_1 \beta(x', y')$, the substitution of which for c and c' is in effect the putting the initial equations in a more complicated form, and nothing more. But there may be more general solutions containing arbitrary functions.

(286.) The theory of the simultaneous inverses is reduced to that of inverses of functions of one subject only, by the equations

$$\phi(x, y) = \Phi \phi^{0,0}(x, y) \quad \phi^{n,n}(x, y) = \Phi^n \phi^{0,0}(x, y);$$

thus Φ^{-1} is the modulus of the convertible inverses, giving

$$\Phi \alpha^{0,0}(\Phi^{-1} \alpha^{0,0}, \Phi^{-1} \alpha^{0,0}) = \Phi \Phi^{-1} \alpha^{0,0} = \alpha^{0,0}(x, y)$$

$$\Phi^{-1} \alpha^{0,0}(\Phi \alpha^{0,0}, \Phi \alpha^{0,0}) = \Phi^{-1} \Phi \alpha^{0,0} = \alpha^{0,0}(x, y).$$

Similarly, Φ_{-1} is the modulus of any inconvertible simultaneous inverse of $\phi(x, y)$, or of $\phi_{-1,-1}(x, y)$, and we have the equation

$$\phi_{-1,-1}(\phi(x, y), \phi(x, y)) = \Phi_{-1} \phi^{0,0}(x, y).$$

Thus, if we suppose $\phi(x, y) = x + y$, we have

$$\phi^{0,0}(x, y) = \frac{x+y}{2} \quad \Phi z = 2z \quad \Phi^{-1} z = \frac{z}{2}$$

$$\phi^{0,-1}(x, y) = \frac{x+y}{4}.$$

If $\phi(x, y) = x^2 - y$, we have

$$\phi^{0,0}(x, y) = \frac{1}{2} + \sqrt{\frac{1}{4} + (x^2 - y)} \quad \Phi z = z^2 - z$$

$$\Phi^{-1} z = \frac{1}{2} + \sqrt{\frac{1}{4} + z} \quad \Phi_{-1} z = \frac{1}{2} - \sqrt{\frac{1}{4} + z}$$

$$\phi^{0,-1}(x, y) = \frac{1}{2} + \sqrt{\frac{3}{4} + \sqrt{\frac{1}{4} + (x^2 - y)}}$$

$$\phi_{-1,-1}(x, y) = \frac{1}{2} - \sqrt{\frac{3}{4} + \sqrt{\frac{1}{4} + (x^2 - y)}}.$$

(287.) Let

$$[\phi_{-1,-1}(\phi(x, y), \phi(x, y))]^{n,n} = \psi^{n,n}(x, y);$$

then $\phi(\psi^{n,n}, \psi^{n,n})$ must be a form of $\phi(x, y)$. This is an extension of the theorem in (34.), and follows from

$$\Phi(\Phi_{-1} \Phi)^n z \text{ being always a form of } \phi z.$$

(288.) The generality of the symbol $\phi(x, y)$ allows us to imagine another mode of substitution, which we may call *internal* substitution. If in ψx we substitute αx for x , and repeat this operation, we have a result capable of being expressed, consistently with the notions contained in ψ and α , by $\psi \alpha^n x$. But if in $\phi(x, y)$ we

suppose $\alpha(x, y)$ to be substituted for x , and $\beta(x, y)$ for y , and continue this any number of times in any specified order of substitution, we cannot express the result by what has preceded. But if we agree to denote

$$\psi(x, y) \text{ by } \psi(x, y)_{\alpha, \beta}^{0,0}$$

$$\psi\{\alpha(x, y), \beta(x, y)\} \text{ by } \psi(x, y)_{\alpha, \beta}^{1,1}$$

we have in

$$\psi(x, y)_{\alpha, \beta}^{m,n} \quad \psi(x, y)_{\beta, \alpha}^{n,m} \quad \psi(x, y)_{\alpha, \beta}^{\overline{m}, \overline{n}}$$

symbols analogous to

$$\psi_{1,2}^{m,n}(x, y) \quad \psi_{2,1}^{n,m}(x, y) \quad \psi^{\overline{m}, \overline{n}}(x, y),$$

and differing from them only in this, that $\alpha(x, y)$ and not $\psi(x, y)$ is substituted for x , and $\beta(x, y)$ not $\psi(x, y)$ for y . Here we may see, 1. That $\alpha = \psi$ and $\beta = \psi$ reduce this to common successive substitution. 2. That if α be a function of x only, and β of y only, the order of substitution is altogether indifferent. Of this last lineal substitution may be regarded as a particular case (262.)

(289.) We shall now proceed to some functional equations containing functions with two independent subjects. We may remark, as we have done before, that the transcendentials which may enter are more and higher than can be ascertained by any methods of solution which we can give. And, as an instance analogous to $\phi x = x \phi(x-1)$ we may assign the equation

$$f'(x, y) \times f(x+y, z) = f(x, z) \times f(x+z, y),$$

which was shown by Euler* to be a property of

$$f(x, y) = \int_0^1 \frac{a^{x-1} da}{(1-a^n)^{\frac{n-y}{n}}}.$$

(290.) To simplify the notation, let it be understood that a functional symbol unaccompanied by any subject means a function of the two subjects x and y , the order of operations being first with respect to x , and next with respect to y , unless the contrary be specified. Let simultaneous substitutions be denoted by the single exponent with a bar over it, instead of the exponent twice repeated; thus, $\bar{n}$ instead of n, n . And let the modulus of any function be denoted by a bar placed over the functional symbol: thus

$$\phi(x, y) = \bar{\phi} \phi^{0,0}(x, y) \text{ or } \phi = \bar{\phi} \phi^{0,0},$$

$$\phi^n(x, y) = \bar{\phi}^n \phi^{0,0}(x, y) \text{ or } \phi^n = \bar{\phi}^n \phi^{0,0}.$$

(291.) Given $\phi(\alpha, \beta) = \phi$, required forms of $\phi(x, y)$.

Firstly, if two particular solutions ω_1 and ω_2 be known, then $\theta(\omega_1, \omega_2)$ is a solution. Or if one particular solution be known, then $\theta \omega_1$ is a solution.

Secondly, we may suppose ϕ to be a zero-function, for if we can solve the equation $\bar{\phi}(\alpha, \beta) = \bar{\phi}^{0,0}$, we have a solution of $\bar{\phi} \phi^{0,0}(\alpha, \beta) = \bar{\phi} \phi^{0,0}$, or of $\phi(\alpha, \beta) = \phi$.

Thirdly, if α and β be the same, and be also zero-functions, then $\theta \alpha(x, y)$ is a solution, for by the property of a zero-function $\alpha(\alpha, \alpha) = \alpha$.

The general solution of the preceding equation depends upon the determination of

$$\alpha(x, y)_{\alpha, \beta}^{\overline{n}, \overline{n}} \text{ and } \beta(x, y)_{\alpha, \beta}^{\overline{n}, \overline{n}}$$

as explicit functions of n, x , and y . Let

$$\alpha(x, y)_{\alpha, \beta}^{\overline{n}, \overline{n}} = V(x, y, n) \quad \beta(x, y)_{\alpha, \beta}^{\overline{n}, \overline{n}} = W(x, y, n),$$

* Legendre, *Mém. de l'Institut*. 1809. *Fonct. Ellipt.* vol. ii. p. 370.

Calculus of Functions and f being any convenient function, obtain

$$n = F(x, y) \text{ from } f(V, W) = 0,$$

it is clear, as in (50.), that

$$V(x, y, n) = V(\alpha, \beta, n-1)$$

$$W(x, y, n) = W(\alpha, \beta, n-1),$$

so that the function F must satisfy the equation

$$n-1 = F(\alpha, \beta),$$

or

$$F(\alpha, \beta) = F(x, y) - 1.$$

From this we may either derive transcendental solutions, such as

$$\phi(x, y) = \theta \cos 2\pi F(x, y);$$

or, by taking another form, f_1 instead of f , and thus deriving a new form F_1 , we see that

$$\phi(x, y) = F(x, y) - F_1(x, y).$$

In this way we may obtain any number of particular solutions, and may thus form a general solution.

(292.) Required, for example, the solution of

$$\phi(x+y, 2y) = \phi(x, y).$$

Let

$$\alpha(x, y) = x + y \quad \beta(x, y) = 2y$$

$$\alpha(x, y)_{\alpha, \beta}^{n, n} = x + (2^n - 1)y \quad \beta(x, y)_{\alpha, \beta}^{n, n} = 2^n y.$$

We have now to determine n by making $x - y + 2^n y$ any function whatsoever of $2^n y$; or, which is the same thing, making

$$2^n = \frac{1}{y} \psi(x-y), \text{ or } n = \psi(x-y) - \frac{\lambda y}{\lambda 2}.$$

Taking two such solutions, the difference of which merely gives an arbitrary function of $x - y$, we find $\theta(x - y)$ as a general form of solution. But we also find a more general solution in

$$\theta\left(\theta_1(x-y), \theta_2 \cos 2\pi \left\{\theta_3(x-y) - \frac{\lambda y}{2}\right\}\right).$$

(293.) Let

$$\phi(ax + by, a'x + b'y) = \phi(x, y)$$

$$\alpha(x, y) = ax + by \quad \beta(x, y) = a'x + b'y.$$

Assume

$$\alpha(x, y)_{\alpha, \beta}^{n, n} = p_n x + q_n y \quad \beta(x, y)_{\alpha, \beta}^{n, n} = p'_n x + q'_n y,$$

which gives

$$p_{n+1} = ap_n + a'q_n$$

$$q_{n+1} = bp_n + b'q_n,$$

and similar equations for p'_n and q'_n . By elimination we get the same equation of differences for the determination of all four, namely,

$$T_{n+2} - (a + b')T_{n+1} + (ab' - a'b)T_n = 0,$$

or

$$T_n = Cr^n + C'r'^n,$$

where r and r' are the roots of

$$R^2 - (a + b')R + ab' - a'b = 0.$$

To determine p_n and q_n , for instance, we must suppose

$$p_0 = 1 \quad q_0 = 0 \quad p_1 = a \quad q_1 = b,$$

and the n , n th functions in question are the following,

$$\left(\frac{r^n - r'^n}{r - r'} a - \frac{r'^n - r r'^n}{r - r'}\right)x + \frac{r^n - r'^n}{r - r'} by$$

$$\frac{r^n - r'^n}{r - r'} a'x + \left(\frac{r^n - r'^n}{r - r'} b' - \frac{r'^n - r r'^n}{r - r'}\right)y.$$

Assume

$$P = \frac{ax + by - rx}{r - r'} \quad Q = \frac{ax + by - rx}{r - r'}$$

$$P' = \frac{a'x + b'y - r'y}{r - r'} \quad Q' = \frac{a'x + b'y - r'y}{r - r'}.$$

Then $Pr^n - Qr'^n$ may be assumed to be any function of $P'r^n - Q'r'^n$, rr' being $ab' - a'b$. The only way in which we can immediately draw a conclusion is that in which we suppose the first to be c times the second, which gives

$$\left(\frac{r}{r'}\right)^n = \frac{Q - cQ'}{P - cP'}$$

the particular solutions which we can obtain (being of the form of $n - n_1$, in the preceding, or in any function of it) give for the algebraical solutions all algebraical functions of

$$\frac{(Q - cQ')(P - c_1P')}{(Q - c_1Q')(P - cP')},$$

which is itself an algebraical function of x and y , which solves the equation. The corresponding transcendental solutions are functions of

$$\cos 2\pi \frac{\lambda(Q - cQ') - \lambda(P - cP')}{\lambda r - \lambda r'}.$$

(294.) We see, then, that whereas in the case of functional equations of one subject there seems to be generally, so far as our methods extend, one algebraical solution, accompanied by a class of solutions containing a particular sort of transcendental, defined as in (119.), in functions of two or more subjects there appear to be an infinite number of algebraical solutions, with a separate class involving also a transcendental defined by the algebraic solution. Or rather, if we consider the greater indeterminateness of the problem as requiring greater generality in the terms employed to express the solution, we should say that, in functions of two subjects, a general algebraical form, containing an *arbitrary function*, stands in the same relation to the solution as the single algebraical function containing an *arbitrary constant* does to the solutions of equations of functions containing one subject only. If we consider the *degree of indeterminateness* of a problem as a conception of comparison which actually must be formed, though not capable of numerical appreciation, we are justified in saying that, within the limits of common algebra, the indeterminateness of ϕx is to that of $\phi(x, y)$ in the same relation as an arbitrary constant to an arbitrary function of given forms.

(295.) If, in the general solution, it should appear that V is *per se* a function of W , the general equation $f(V, W) = 0$ gives $V = \text{constant}$. The resulting algebraical solution is reduced to a constant, but it will also appear that some of the transcendental solutions are reduced to algebraical solutions, in the same manner as in (129.) The successive n , n th functions will assume a certain periodic character at the same time.

To apply this, suppose we require that class of functions which is not changed by inverting x and y , provided that at the same time x is changed into $a'x$, and y into by . That is, required the solution of

$$\phi(by, a'x) = \phi(x, y);$$

considering this as a case of the last problem, we have $R^2 - a'b = 0$, and the successive functions involve the symbol of discontinuity $(-1)^n$. The algebraic solution

Calculus of Functions. given above is reduced to a constant, since it will be found that $P = \text{constant} \times P'$ and $Q = \text{constant} \times Q'$, and that $P r^n - Q r'^n$ is a function of $P' r^n - Q' r'^n$. To determine n , we assume then

$$P r^n - Q r'^n = \text{const.}, \text{ or } c^n \{P - Q(-1)^n\} = \text{const.},$$

where $c = \sqrt{a'b}$. The only case in which we can determine a result is where the constant vanishes, which gives

$$\begin{aligned} n &= \frac{1}{\lambda(-1)} \lambda \cdot \frac{P}{Q} = \frac{1}{\pi \sqrt{-1}} \lambda \frac{P}{Q} \\ \cos 2\pi n &= \left(\frac{P}{Q}\right) + \left(\frac{Q}{P}\right)^2 \\ &= \left(\frac{by-r'x}{by-rx}\right)^2 + \left(\frac{by-rx}{by-r'x}\right)^2 \\ &= \left(\frac{\sqrt{b}y - \sqrt{a'}x}{\sqrt{b}y + \sqrt{a'}x}\right)^2 + \left(\frac{\sqrt{b}y + \sqrt{a'}x}{\sqrt{b}y - \sqrt{a'}x}\right)^2 \end{aligned}$$

either term of which is a solution, and which gives as a general solution

$$\theta \left(\frac{\sqrt{b}y - \sqrt{a'}x}{\sqrt{b}y + \sqrt{a'}x} \right)^2,$$

where θ must not directly invert the square.

By making $b = 1$, $a' = 1$, we have thus obtained, independently of particular solutions obtained from observation, the known general form of symmetrical functions, namely, $\theta(\theta_1, \theta_2, \dots)$, θ_1, θ_2 &c. being such functions as θ just given.

(296.) We shall now show the propriety of the distinction between what we have called (for want of better names) *external* and *internal* simultaneous substitution, denoted by

$$\psi^{\alpha, \beta}(x, y) \text{ and } \psi(x, y)^{\alpha, \beta}.$$

When we propose the equation

$$\psi(\alpha, \beta) = \psi(x, y),$$

the general method requires some species of successive substitution, in which x and y shall be zero-functions. This is not the case as to the external substitution, in which the defined relation of ψ to both x and y gives, as we have seen, one zero-function only. But in the internal substitution we treat both x and y as independent, and the substitution has no dependence on the form of ψ , so that we are able to define x and y as the zero-functions of α and β . But if we propose the equation

$$\psi \alpha(x, y) = \psi \alpha^0(x, y),$$

in which α^0 is itself the zero-function of α , relatively to the notions implied in internal simultaneous substitution, we may proceed with that substitution in the same manner as in (50.) For if we now determine n from the equation

$$\alpha^{\alpha, \beta}(x, y) = F(\alpha^0, n) = \mu \cos 2\pi n, n = A \alpha^0(x, y),$$

we have evidently a solution of the equation

$$\phi \alpha = \phi \alpha^0 - 1;$$

but not of any form in which x and y enter through two functions. The equation

$$\phi(\alpha, \beta) = \phi(\alpha^0, \beta^0)$$

is reducible to the case already solved in (117.), by writing it in the form

$$\phi(\bar{\alpha} \alpha^0, \bar{\beta} \beta^0) = \phi(\alpha^0, \beta^0), \text{ or } \phi(\bar{\alpha} x, \bar{\beta} y) = \phi(x, y). \quad \text{Calculus of Functions.}$$

(297.) Let us now propose $\phi(\alpha, \alpha) = \phi(x, y)$ in the case where α is a function with a constant modulus, or an indefinite zero-function. If we substitute $\alpha(x, y)$ instead of both x and y , the equation of definition $\alpha(z, z) = \text{constant}$ gives $\phi(c, c) = \phi(\alpha, \alpha)$, or ϕ itself must be another function of the same kind. But this gives $\phi(x, y) = \text{constant}$, and the equation therefore has no continuous solution except this. That is, we cannot find a function which shall remain unchanged when, for instance, $x - y$ is substituted both for x and y . And, indeed, it would be the property of such a function to be reduced to a constant by $y = x$; it could, therefore, be only $\theta(y - x)$, which does not remain the same when y and x are both substituted for x .

When $\phi(\alpha, \alpha) = \phi(x, y)$, without the condition of a constant modulus, we obtain a solution by finding

$$n = A(x, y) \text{ from } \alpha(x, y)^{\alpha, \alpha} = F(n, x, y) = \mu \cos 2\pi n,$$

or, which is in this case the same thing, from

$$\alpha^{\alpha, \alpha}(x, y) = F(n, x, y) = \mu \cos 2\pi n;$$

the solution of the equation is then $\theta \cos 2\pi A(x, y)$; and here we have a case in which, generally speaking, there is no algebraical solution, but only a transcendental solution. This bears a great analogy with the case of subjects of a single function, which will appear still more when we show that, if the modulus of α be a periodic function, algebraical solutions may be obtained. Firstly, $\bar{\phi} z$ being the modulus of $\phi(x, y)$, it is clear that $\phi(\alpha, \alpha)$ is the same thing as $\bar{\phi} \alpha$, that is, as $\bar{\phi} \alpha \alpha^0$. We can then satisfy

$$\phi(\alpha \alpha) = \phi(x, y),$$

by means of $\bar{\phi} \alpha \alpha^0(x, y) = \bar{\phi} \phi^0(x, y)$, which, because one zero-function cannot be a function of x and y through another, gives $\phi^0 = \alpha^0$, or the solution has the same zero-function as the given function. We have then $\bar{\phi} \alpha z = \bar{\phi} z$, which admits algebraical solutions, as before described, only when $\bar{\alpha} z$ is a periodic function. For example, suppose the equation to be

$$\phi\left(\frac{1}{x+y}, \frac{1}{x+y}\right) = \phi(x, y),$$

where

$$\alpha(x, y) = \frac{1}{x+y}, \quad \bar{\alpha} z = \frac{1}{2z}, \quad \bar{\alpha}^2 z = z.$$

Hence

$$\bar{\phi} z = \xi \frac{1}{2z} = \theta\left(z + \frac{1}{2z}\right), \quad \alpha^0 = \frac{x+y}{2}$$

$$\bar{\phi} \phi^0 z = \bar{\phi} \alpha^0 z = \theta\left(\frac{x+y}{2} + \frac{1}{x+y}\right),$$

which will be found to be a solution.

Similarly,

$$\phi(\sqrt{1-xy}, \sqrt{1-xy}) = \phi(x, y)$$

gives

$$\phi(x, y) = \theta(\sqrt{xy} + \sqrt{1-xy}, \sqrt{xy} \sqrt{1-xy}).$$

(298.) The inverse of $\theta(x, y)$ or $\theta(x, y)^{\alpha, \beta}$ is the function in which α and β must be simultaneously substituted for x and y , in order that $\theta(x, y)$ may result. Let us then suppose

Calculus of
Functions.

from which let

$$\alpha(x, y) = x' \quad \beta(x, y) = y',$$

$$x = \alpha_1(x', y') \quad y = \beta_1(x', y').$$

We have then identically

$$\alpha\{\alpha_1(x', y'), \beta_1(x', y')\} = x' \quad \beta\{\alpha_1(x', y'), \beta_1(x', y')\} = y'$$

or

 $\theta\{\alpha_1(x, y), \beta_1(x, y)\}$, is the function required; that is,

$$\theta\{\alpha_1(x, y), \beta_1(x, y)\} = \theta(x, y)^{-1, -1}_{\alpha, \beta}.$$

The inverses which we mean to imply by this notation are also those which satisfy the converted forms

$$\alpha_1\{\alpha(x, y), \beta(x, y)\} = x \quad \beta_1\{\alpha(x, y), \beta(x, y)\} = y;$$

 these two equations answering to $\phi^{-1}\phi x = x$, and the first two to $\phi\phi^{-1}x = x$. Those which satisfy the first pair only may be considered as giving A and B, incon-vertible inverses.

 By observing different functions, we may ascertain, as in (34.), that every form of α_1 and β_1 may be made a convertible inverse in some particular method of considering the two fundamental equations, and also that if this particular method be retained in form, though the performance of direct upon inverse operations destroys all real difference of results, yet the final results of the operations analogous to $\phi\phi^{-1}x$ may be thus preserved. From which it appears, by reasoning similar to that in (34.), that $\alpha(A^n, B^n)$ and $\beta(A^n, B^n)$ will always represent one or other of the forms of α and β respectively: and also that, if the number of forms of α and β be finite, A and B must be periodic functions, which give for some one value of n

$$A(x, y)^{\overline{n, n}}_{A, B} = x \quad B(x, y)^{\overline{n, n}}_{A, B} = y.$$

As an instance, let us take

$$\alpha = x^2 + y = x'$$

$$\beta = 2x + y = y'.$$

 By choosing as our direct process of inversion the subtraction of the second equation from the first, and then proceeding arithmetically, we find (r being a square root of unity)

$$x = 1 + r\sqrt{1 + (x' - y')} = \alpha_1(x', y')$$

$$y = y' - 2 - 2r\sqrt{1 + x' - y'} = \beta_1(x', y').$$

This gives

$$\alpha_1(\alpha, \beta) = A(x, y) = 1 + r(x - 1)$$

$$\beta_1(\alpha, \beta) = B(x, y) = 2x + y - 2 - 2r(x - 1)$$

$$A(x, y)^{\overline{2, 2}}_{A, B} = 1 + r^2(x - 1) = x$$

$$B(x, y)^{\overline{2, 2}}_{A, B} = 2x + y - 2 - 2r^2(x - 1) = y.$$

Both A and B are then periodic, and of the second degree, and we have

$$\alpha(A, B) = r^2(x - 1)^2 + 2x + y - 1 = \alpha$$

$$\beta(A, B) = 2x + y = \beta.$$

 (299.) If $\theta(x, y)$ be considered as $\theta(x, y)^{\overline{0, 0}}_{\alpha, \beta}$ then by considering $\phi\theta(\phi^{-1}x, \phi^{-1}y)$ as $[\phi\theta(\phi^{-1}x, \phi^{-1}y)]^{\overline{0, 0}}_{\phi\alpha, \phi\beta}$ we have the equation

$$[\phi\theta(\phi^{-1}x, \phi^{-1}y)]^{\overline{n, n}}_{\phi\alpha, \phi\beta} = \phi : \theta(\phi^{-1}x, \phi^{-1}y)^{\overline{n, n}}_{\alpha, \beta};$$

 where, by the colon following the functional symbol, we understand that the change of θ into $\phi\theta$, x into $\phi^{-1}x$, and y into $\phi^{-1}y$ is the final operation, after all that is

 otherwise denoted has been performed. If then we have a pair of periodic functions, as in the last article, every pair of corresponding derivatives is periodic in the same manner. But it is obvious that we cannot, continuously at least, make $\theta_1(x, y)^{\overline{0, 0}}_{\alpha_1, \beta_1}$ a derivative of $\theta(x, y)^{\overline{0, 0}}_{\alpha, \beta}$, the six functional symbols meaning any whatever.

 (300.) If we now review articles (197.) and (235.), we shall see that the particular assumption of a change of x into αx , though essential to that case, is not in its specific character necessary to the solution. Neither the process nor the result depends upon any thing except there being some change which changes B_0 into B_1 , c_0 into c_1 , &c. simultaneously, and which is of such a kind that $B_n = B_0$, $c_n = c_0$, &c., followed by recurrence. And in the place where αx seems to enter specifically, namely, in $\xi\alpha x$, we see that this symbol merely defines a function, which does not change when the changes supposed in the problem are made. Consequently we have then solved the equation

$$P_0 = B_0 + c_0 P_1;$$

 where P_0 , B_0 , c_0 , are any functions whatsoever, which are by any hypothesis simultaneously changed into P_1 , B_1 , and c_1 , provided that successive operations reproduce P_0 , B_0 , and c_0 . By (235.) we can solve the general case.

(301.) One important application of this is the solution of the equation

$$\phi(x, y) = \beta(x, y) + \gamma(x, y)\phi(\mu, \nu);$$

where

$$\mu(x, y)^{\overline{n, n}}_{\mu, \nu} = x \quad \nu(x, y)^{\overline{n, n}}_{\mu, \nu} = y,$$

making

$$\phi(x, y) = P_0 \quad \beta(x, y) = B_0 \quad \gamma(x, y) = c_0$$

$$\phi(x, y)^{\overline{1, 1}}_{\mu, \nu} = P_1 \quad \beta(x, y)^{\overline{1, 1}}_{\mu, \nu} = B_1, \text{ \&c. ;}$$

 writing instead of $\xi(\alpha x)$ any function of

$$V, V', V'' \dots W, W', W'' \dots$$

 where $V, V', V'' \dots$ are symmetrical functions of

$$\mu(x, y) \quad \mu(x, y)^{\overline{1, 1}}_{\mu, \nu} \dots \mu(x, y)^{\overline{n-1, n-1}}_{\mu, \nu}$$

 and $W, W', W'' \dots$ are symmetrical functions of

$$\nu(x, y) \quad \nu(x, y)^{\overline{1, 1}}_{\mu, \nu} \dots \nu(x, y)^{\overline{n-1, n-1}}_{\mu, \nu},$$

we have in (197.) and (235.) solutions of the equations.

 (302.) From this it seems to us that the necessary restrictions upon the generality of Abel's Theorem (see (90.), note) may be obtained. Proceeding in the manner of that most excellent analyst, let us suppose an irreducible* algebraic equation $f(x) = 0$ of the n th degree, between two of whose roots, a_1 and a , the equation $a_1 = \theta a$ can be shown to exist. Then $f x = 0$ and $f\theta x = 0$ have a common root, and, consequently, have all their roots in common, for if not, a reducing factor might be obtained by the usual process, which is against hypothesis. Therefore θa is a root of $f\theta x = 0$, which, therefore, has a root in common with $f\theta^2 x = 0$, and so on. Consequently, $a, \theta a, \theta^2 a \dots$ are all roots of $f x = 0$. But as this has only n roots, the preceding series continued *ad infinitum* can only have a finite number of values less than n , consequently, as in (34.), it can be shown that we must have $\theta^m x = x$, where $m = n$. Suppose the first case, and let b be a root of $f x = 0$, which is not included in the preceding periodic

 * Namely, in which $f x$ cannot be divided by any rational algebraic function of a lower degree.

Calculus of
Functions.

series, then, by the same reasoning, $b, \theta b, \dots, \theta^{m-1}b$ must also be roots. If $2m$ be not so great as n , (it cannot be greater,) then $c\theta c, \dots, \theta^{m-1}c$ must be roots, and so on, that is, m must be a submultiple of n .

Now, from the process in (197.), it is evident that we can assign m of these roots, when we know one of them, and also the law of the function θ , provided we can ascertain the existence of a functional equation between θx and x which admits of solution. It is not necessary that we should absolutely know θx , for by the preceding method it is sufficient that we know B_0 and B_1 , from which θ can be inferred.

(303.) Further consideration points out to us that it is due as well to the memory of talents which we cannot sufficiently admire, as to the weight they will have, and ought to have, with our readers, to point out more explicitly than we have yet done, our objection to the theorem in question. The final process of M. Abel is as follows. To take a case, let n in (302.) be a prime number, so that m cannot be a submultiple of n , and must be equal to n itself. Now if such a relation as $a_1 = \theta a$ exist among two of the roots, it follows, as before, that the roots must be $a, \theta a, \theta^2 a, \dots, \theta^{n-1} a$. Consequently we can express any *disjunctively** periodical function of $a, \theta a$, &c. as a function of the coefficients of the equation. Consider, therefore, the function $\psi x = (x + \theta x \cdot r + \theta^2 x \cdot r^2 + \dots + \theta^{n-1} x \cdot r^{n-1})^n$, where $r^n = 1$, which gives $\psi \theta x = \psi x$, and, consequently,

$$\psi x = \frac{1}{n} (\psi x + \psi \theta x + \psi \theta^2 x + \dots + \psi \theta^{n-1} x),$$

or ψx is a symmetrical function of $x, \theta x, \theta^2 x, \dots$ and, therefore, can be expressed in terms of the coefficients of the equation. Let this be done, and let the result be U^n ; then calling $U, U_1, \dots$ the values of $(\psi x)^{\frac{1}{n}}$ corresponding to the roots $r, r_1, \dots$ of $r^n - 1$, it is easily proved that

$$x = \frac{1}{n} (U + U_1 + \dots + U_{n-1}).$$

Now the words in italics contain too much generalization: the function ψx is only periodically symmetrical, not disjunctively so: it remains the same if, when x becomes θx , θx also becomes $\theta^2 x$, and so on up to $\theta^{n-1} x$, which becomes $\theta^n x$ or x . But it is not allowable to interchange x and θx without the other interchanges: nor is

$$(a + b r + c r^2 + \dots + q r^{n-1})^n$$

such a function as can be expressed in terms of $a + b + \dots, a b + a c + \dots$ &c., without the previous solution of the equation of the n th degree. For if so, let the preceding be (remember that r^n recurs)

$$A_0 + A_1 r + \dots + A_{n-1} r^{n-1};$$

and writing $\cos t + \sqrt{-1} \sin t$ for r , we find that

* We cannot thus express any *periodically* symmetrical function in the same manner. For instance, of the functions

$$a^2 b^2 + b^2 c^2 + c^2 a^2 \text{ and } a b^2 + b c^2 + c a^2,$$

we can express the first in terms of

$$a + b + c, ab + bc + ca, abc,$$

but not the second unless we first find a, b , and c ; that is, solve the equation in question.

We must make M. Abel our excuse for having fallen into the same error in article (130.) in the use of the word symmetrical. It is true that we had previously defined the word to apply both to the disjunctive and periodical kinds; but, to the best of our recollection, we had forgotten our own distinction.

Calculus of
Functions.

$$A_0 + A_1 \cos t + A_2 \cos 2t + \dots + A_{n-1} \cos (n-1)t$$

$$\text{and } A_0 + A_1 \sin t + A_2 \sin 2t + \dots + A_{n-1} \sin (n-1)t$$

must be disjunctively symmetrical functions of $a, b, \dots$. That A_0, A_1 , &c. are not severally of this kind, except in the case of $n = 2$, may be made evident by expansion: for instance, when $n = 3$, $A_1 = 3(a^2 b + c^2 a + b^2 c)$, which is only periodically symmetrical. Neither then can the preceding expressions remain the same under partial interchanges; for in that case, by making a sufficient number of partial interchanges, we might determine $\cos t, \cos 2t$, &c. in terms of $A_0, A_1, \dots$ and a disjunctively symmetrical function; that is, we might find rational expressions for them, which cannot be. The complete development of $(a + b r + c r^2)^3$, where $r^3 = 1$ is (D_1 and D_2 standing for two disjunctively symmetrical functions)

$$D_1 = \frac{D^2}{2} + (a^2 b - a b^2 + c^2 a - c a^2 + b^2 c - b c^2) \frac{3\sqrt{-3}}{2},$$

in which the coefficient of $\sqrt{-3}$ will not admit a single interchange, and allow the whole to be still considered as symmetrical, unless we, at the same time, use a different sign for $\sqrt{-3}$, that is, suppose ourselves to have taken a different value of r at the commencement of the process.

(304.) We shall now consider some forms of simultaneously periodic functions. From (280.) it is evident that any two functions being periodic and of the n th order,* any two derivatives have the same property. From (293.) it is obvious that $a x + b y$ and $a' x + b' y$ are n thly periodic, when r and r' the roots of

$$R^2 - (a + b') R + a b - a' b = 0,$$

are also different roots of $R^n = 1$. If a, a' , &c. are to be real, then $a + b' = 2 \cos N$ $a b' - a' b = 1$ where N denotes $\frac{2m\pi}{n}$, m being a whole number. This gives

$$a' = -\frac{1}{b} (a^2 - 2a \cos N + 1) \quad b' = 2 \cos N - a;$$

but if we suppose $r = r' = 1$, then we have

$$(a x + b y)^{n-1} = (n a - n + 1) x + n b y$$

$$(a' x + b' y)^{n-1} = n a' x + (n b' - n + 1) y,$$

$$a' = -\frac{(a-1)^2}{b} \quad b' = 2 - a,$$

so that there can be no periodic function in this case except when $b = 0$ $a' = 0$ $a = 1$ $b' = 1$.

We have then a class of simultaneously periodic functions in

$$\phi(a \phi^{-1} x + b \phi^{-1} y) \quad \phi(a' \phi^{-1} x + b' \phi^{-1} y)$$

$$a' = -\frac{1}{b} (a^2 - 2a \cos N + 1) \quad b' = 2 - a,$$

for it is evident that similar derivatives of such functions have the same property.

(305.) We shall now investigate the conditions of simultaneous convertibility, or the solution of the equation

$$\phi(\psi, \psi) = \psi(\phi, \phi).$$

* The reader must recollect that what we now call the n th order answers to the $(n+1)$ th in subjects of a single function. Thus $a(x, \beta) = x$ shows periodicity of the first order; but if β were $= y$, and $a(x, y)$ were called μx , then $a(x, y)$ or $a(x, y)^{\frac{1}{n}}$ would be $\mu^2 x$.

Calculus of Functions.

1. If ϕ and ψ be both zero-functions, then this equation is reduced to $\psi = \phi$, which is the only solution.

2. If one only, ϕ , be a zero-function, the equation is reduced to $\psi = \psi(\phi, \phi)$, which has been already considered.

3. If both be functions with constant moduli it is sufficient that the two moduli should be the same.

4. If one only, ϕ , have a constant modulus, the equation is reduced to $\psi(\phi, \phi) = \text{constant}$, or the other is of the same kind.

5. If both have variable moduli, and therefore variable zero-functions, we see that $\phi(\psi, \psi)$ being $\bar{\phi}\psi$ or $\bar{\phi}\bar{\psi}\psi^0$, and $\psi(\phi, \phi)$ being $\bar{\psi}\phi$ or $\bar{\psi}\bar{\phi}\psi^0$, we must have

$$\bar{\phi}\bar{\psi}\psi^0 = \bar{\psi}\bar{\phi}\phi^0,$$

which shows that ψ^0 and ϕ^0 must be the same; for if not, one zero-function would be a function of another;

and that the moduli $\bar{\phi}$ and $\bar{\psi}$ must be convertible.

For instance, having the convertible functions $2x^2 - 1$ and $4x^3 - 3x$, and the zero-function $\sqrt{xy}$, we find the simultaneously convertible functions

$$2xy - 1 \text{ and } \sqrt{xy}(4xy - 3).$$

In a similar manner, the equation

$$\phi(x, y)_{\phi, \psi}^{\bar{n}, \bar{n}} = \psi(x, y)_{\phi, \psi}^{\bar{m}, \bar{m}}$$

may be reduced to the solution of the equation $\bar{\phi}\bar{\psi}^nz = \bar{\psi}\bar{\phi}^nz$, which we cannot solve generally. One simple solution may be obtained by finding convertible functions $\bar{\phi}$ and $\bar{\psi}$, which satisfy $\bar{\psi}^{n-1}x = x\bar{\phi}^{n-1}x = x$. Such are rx and $r'z$, where $r^{n-1} = 1$ and $r'^{n-1} = 1$; from which it follows that $\bar{\phi}x = \theta r\theta^{-1}z$ and $\theta r'\theta^{-1}z$ will be convertible periodic functions of the kind required; and $\theta r\theta^{-1}\alpha^0(x, y)$ and $\theta r'\theta^{-1}\alpha^0(x, y)$ will be solutions of the equation.

(306.) The solution of $\phi(\alpha, \beta) = \phi(x, y) - 1$, given in (291.), leads, as in the case of functions of one subject, to those of

$$\phi(\alpha, \beta) = \phi(x, y) \pm c.$$

$$\phi(\alpha, \beta) = c\phi(x, y) \text{ and } \phi(\alpha, \beta) = (\phi(x, y))^c;$$

and if we denote by $\xi(\alpha, \beta)$ a function of x and y , which is not changed by the simultaneous substitution of α for x , and β for y , we find that the general solution of $\phi(\alpha, \beta) = A \times \phi(x, y)$ is $\varpi(x, y) \times \xi(\alpha, \beta)$, where $\varpi(x, y)$ is a particular solution, and also that the solution of

$$\phi(x, y) = A(x, y) + B(x, y)\phi(\alpha, \beta)$$

is

$$\phi(x, y) = \varpi(x, y) + \varpi_1(x, y)\xi(\alpha, \beta),$$

where ϖ is a particular solution of the equation itself, and ϖ_1 of the equation deprived of the term A . The perfect generality of this solution may be established in the same manner as in (176.); but we may not assume that we can in any case arrive at the most general form of $\xi(\alpha, \beta)$.

(307.) Mr. Babbage* has given a method, amongst others, of obtaining $\xi(\alpha, \beta)$ as follows. To solve $\phi(\alpha, \beta) = \phi(x, y)$, assume $\phi_1(f, f_1)$ for ϕ , which gives

$$\phi_1(f, f_1) = \phi_1\{f(\alpha, \beta), f_1(\alpha, \beta)\};$$

if f and f_1 be particular solutions, any form of ϕ_1 is

* Essay, &c., part ii. prob. 4.

sufficient; but an entirely different class of solutions will (or, as far as we can see, may) arise if we suppose ϕ_1 to be a symmetrical function of x and y , and suppose

$$f_1(\alpha, \beta) = f(x, y) \quad f(\alpha, \beta) = f_1(x, y),$$

which give, by internal substitution of α and β ,

$$f_1\{\alpha(x, y)_{\alpha, \beta}^{1,1}, \beta(x, y)_{\alpha, \beta}^{1,1}\} = f_1(x, y)$$

$$f\{\alpha(x, y)_{\alpha, \beta}^{1,1}, \beta(x, y)_{\alpha, \beta}^{1,1}\} = f(x, y).$$

It is sufficient for these, that f and f_1 be particular solution of the given equation, for $f(\alpha, \beta) = f$ gives

$$f\{\alpha(x, y)_{\alpha, \beta}^{n,n}, \beta(x, y)_{\alpha, \beta}^{n,n}\} = f(x, y);$$

but the same condition is not necessary; for instance, the forms of f and f_1 are any whatsoever, which satisfy the more general equation just given. For example, they are altogether immaterial if

$$\alpha(x, y)_{\alpha, \beta}^{1,1} = x, \quad \beta(x, y)_{\alpha, \beta}^{1,1} = y,$$

which are satisfied if

$$\alpha(x, y) = \theta\left(a + b\theta^{-1}x + \frac{b^2 - 1}{b}\theta^{-1}y\right)$$

$$\beta(x, y) = \theta\left(\frac{ab}{1 - b} - b\theta^{-1}x - b\theta^{-1}y\right).$$

In all such cases $\phi(x, y) = \phi(\alpha, \beta)$ is identically satisfied by $\phi = \chi(\alpha, \beta)$. This proves the impossibility of deriving any two functions from any two given forms, which, by analogy, might at first be supposed possible.

The following conditions also make $\phi = \chi(\alpha, \beta)$ satisfy the equation $\phi(\alpha, \beta) = \phi(x, y)$ identically:

$$\alpha(x, y) = \theta\{(\theta^{-1}x)^{\sqrt{1-n^2}}(\theta^{-1}y)^n\}$$

$$\beta(x, y) = \theta\{(\theta^{-1}x)^n(\theta^{-1}y)^{-\sqrt{1-n^2}}\}.$$

(308.) We have already (117.) given the general solution of

$$\phi(x, y) = \phi(\alpha x, \beta y),$$

but we can divide the solutions which we may find into two classes, *disjunctive* solutions, in which either substitution satisfies the equation, and *simultaneous* solutions, in which both substitutions are necessary. The first solutions satisfy both of

$$\phi(x, y) = \phi(\alpha x, y) = \phi(x, \beta y);$$

and, therefore,

$$\phi(x, y) = \phi(\alpha x, \beta y);$$

and form the solution given by Mr. Babbage;* the second class may be found by the method given in (117.)

For instance, suppose we have to solve

$$\phi(x, y) = \phi\left(-x, \frac{1}{y}\right),$$

the class of disjunctive solutions is contained in

$$\phi(x, y) = \phi\left(x^2, y + \frac{1}{y}\right);$$

but by using the method in (117.) we may obtain such solutions as $x\left(y - \frac{1}{y}\right), \lambda y(e^x - e^{-x})$; or, generally,

$$(\alpha^2 x = x \quad \beta^2 y = y), \quad \psi(\phi(x, y)\phi(\alpha x, \beta y)),$$

where ψ is a symmetrical function of the two forms of ϕ . This solution is, generally, simultaneous.

(309.) The equation $\phi(\alpha x, \alpha y) = \phi(x, y)$ admits of

* Essay, &c., part ii. prob. 1.

Calculus of Functions.

solution as follows. Since the moduli must be the same, we have $\bar{\phi} \alpha z = \bar{\phi} z$, or $\bar{\phi} = \xi \alpha$; and, since the zero-functions must be the same, we have

$$\alpha^{-1} \bar{\phi}^0(\alpha x, \alpha y) = \bar{\phi}^0(x, y) \text{ or } \bar{\phi}^0(\alpha x, \alpha y) = \alpha \bar{\phi}^0(x, y).$$

But of the latter we can give no general solution, though we can make a general solution of the given equation serve to show in what the difficulty lies. Let $\phi(x, y) = \psi(Ax, Ay)$, where Ax is the exponential inverse of αx ; then

$$\phi(\alpha x, \alpha y) = \psi(Ax - 1, Ay - 1) = \psi(Ax, Ay),$$

or

$$\psi(x - 1, y - 1) = \psi(x, y),$$

whence

$$\psi(x, y) = \theta(y - x),$$

or

$$\phi(x, y) = \theta(Ay - Ax),$$

and therefore has a constant modulus.

If we suppose $\phi(\alpha, \alpha) = \alpha \phi(x, y)$, we find $\bar{\phi} \alpha = \alpha \bar{\phi}$, and $\alpha^{-1} \bar{\phi}^0(\alpha, \alpha)$ (the zero-function of $\phi(\alpha, \alpha)$) = $\bar{\phi}^0$, the zero-function of $\alpha \phi$. This gives $\bar{\phi}^0(\alpha, \alpha) = \alpha \bar{\phi}^0$, or the zero-function of ϕ must also be a solution of the equation. Consequently, we must find the general solution of $\phi(\alpha, \alpha) = \alpha \phi(x, y)$, in order to find that of $\phi(\alpha, \alpha) = \phi(x, y)$. By the method in (117.) the solution of the first is found by eliminating m, n , and p , between four equations of the form

$$F(\alpha^m x, \alpha^n y, \alpha^p z) = 0,$$

and then determining z in terms of x and y .

It may be useful to observe that the method already employed, which produces a result with a constant modulus, is equivalent to allowing three of the equations to be

$$\alpha^m x = c, \quad \alpha^n y = c', \quad \alpha^p z = c'',$$

and proposing as the fourth a relation between m, n , and p , of the form $p = \theta(m, n)$, where θ is then to be found.

Without affecting the generality of the process in (117.), we may suppose any relations to exist between m, n ; and p which are consistent with contemporaneous increase and decrease of these quantities by unity. Assume $n = m + c, p = m + c'$. Also, since $\alpha^m x$ is $A^{-1}(Ax - m)$, &c., and any functional relations between these may be chosen, we may write $Ax - m$ in place of $\alpha^m x$. Assume

$$Az - p + q(Ax - m) + q'(Ay - n) = 0$$

$$1 + q + q' = 0;$$

this allows us to eliminate m, n , and p , and gives

$$z = A^{-1}\{C - qAx + (1 + q)Ay\} = \phi(x, y),$$

which satisfies $\phi(\alpha, \alpha) = \alpha \phi$. The same, therefore, does its zero-function, which will be found from the equation

$$A^{-1}\{C - qAt + (1 + q)At\} \\ = A^{-1}\{C - qAx + (1 + q)Ay\}$$

to be

$$\bar{\phi}^0(x, y) = A^{-1}\{(1 + q)Ay - qAx\}.$$

Here, then, is a zero-function, which satisfies

$$\bar{\phi}^0(\alpha, \alpha) = \alpha \bar{\phi}^0(x, y),$$

whence

$$\phi(\alpha, \alpha) = \phi(x, y)$$

is satisfied by

$$\phi(x, y) = \theta \cos 2\pi \{(1 + q)Ay - qAx\}.$$

(310.) Before proceeding further, it will be convenient to recapitulate some of the forms of functions which have, or have not, constant moduli.

1. No symmetrical functions whatsoever have constant moduli.

2. No algebraical integral functions, except those of the form $(x - y)\phi(x, y) + c$.

3. All ratios of homogeneous functions of the same degree; for instance, such as

$$\frac{ax + by}{a'x + b'y} \quad \frac{x^2 + 2xy}{xy + y^2}, \text{ \&c.}$$

4. Ratios of algebraical functions, which have the sum of the coefficients of each order of terms the same, or given multiples of the same, such as

$$\frac{a + bx + cy + ex^2 + gxy - hy^2}{a' + b'x + c'y + e'x^2 + h'y^2},$$

where

$$a = m a' \quad b + c = m(b' + c')$$

$$e + g - h = m(e' + h').$$

5. All functions whatsoever of the above, and all functions of the form

$$(x - y) \chi(x, y) + c,$$

where $\theta(0) = 0$, and $\chi(x, x)$ is finite.

(311.) Let $\bar{\phi}^n(x, y) = \alpha(x, y)$, or $\bar{\phi}^n \phi(x, y) = \alpha \alpha^0(x, y)$. Hence the zero-functions must be the same, or one zero-function would be a function of another.

Hence the equation is reduced to $\bar{\phi}^n z = \alpha z$, a functional equation of one subject.

The same reasoning applies to every equation of the form

$$F(\alpha, \beta, \gamma, \dots, \phi, \bar{\phi}^2, \bar{\phi}^3, \dots, \bar{\phi}^n) = 0,$$

if the zero-functions of α, β, γ , &c. be the same.

(312.) In all cases where we have more than one known function not entering under the unknown functional sign, we may proceed as follows. Let the equation be

$$\bar{\phi}^2(x, y) = \alpha(x, y) + \beta(x, y)\phi(x, y).$$

As this must hold when $x = y$, let that supposition be made, which gives

$$\bar{\phi}^2 x = \bar{\alpha} x + \bar{\beta} x \bar{\phi} x,$$

which equation the modulus of ϕ must satisfy. Suppose ϖx to be a particular solution of the last equation, which is now known, and let V be the unknown zero-function which must be introduced, so that $\varpi(V)$ may solve the original equation. Then we have

$$\varpi^2(V) = \alpha(x, y) + \beta(x, y)\varpi(V),$$

in which every thing is known except V . Let V be thence determined. One or more of its values are zero-functions, because, by the supposition on which ϖ was obtained, $x = y$ and $V = x$ are simultaneously true. Consequently, for every different form which can be given to ϖ , a different zero-function is requisite; for it is obvious, that if we could obtain ϖ with an arbitrary function we could not solve the equation which gives V in finite terms. If in the second equation we substitute $\bar{\phi}^0(x, y)$ for x , we have

$$\bar{\phi}^2(x, y) = \bar{\alpha} \bar{\phi}^0(x, y) + \bar{\beta} \bar{\phi}^0(x, y) \phi(x, y),$$

which, with the first equation, determines both $\phi(x, y)$ and $\bar{\phi}^2(x, y)$, and therefore gives an equation which

Calculus of Functions.

Calculus of Functions. $\phi^0(x, y)$ must satisfy. The determination of the equation will involve an indeterminate fraction, which will render it not easy to use. But it thus appears that the first equation, at most, takes a certain class of the solutions of every equation which can be formed by retaining the moduli of α and β , and substituting the same zero-functions.

(313.) For brevity, write α^0 for $\bar{\alpha}^0(x, y)$, &c., and take the two equations

$$\bar{\phi}^2 = \bar{\alpha}\alpha^0 + \bar{\beta}\beta^0 \cdot \phi$$

$$\phi^2 = \bar{\alpha}\phi^0 + \bar{\beta}\phi^0 \cdot \phi,$$

omitting subjects, and putting a full stop between factors. We then have

$$\bar{\phi}^2 = \frac{\bar{\alpha}\alpha^0 \cdot \bar{\beta}\phi^0 - \bar{\alpha}\phi^0 \cdot \bar{\beta}\beta^0}{\bar{\beta}\phi^0 - \bar{\beta}\beta^0} \dots (\bar{\phi}^2)$$

$$\phi = -\frac{\bar{\alpha}\phi^0 - \bar{\alpha}\alpha^0}{\bar{\beta}\phi^0 - \bar{\beta}\beta^0} \dots (\phi).$$

Let α^0 and β^0 be as in the first two of the following equations; and let ϕ^0 be assumed as in the third.

$$\alpha^0 = \frac{x+y}{2} + A(x-y) \cdot A(x, y)$$

$$\beta^0 = \frac{x+y}{2} + B(x-y) \cdot B(x, y)$$

$$\phi^0 = \frac{x+y}{2} + F(x-y) F(x, y).$$

The determination of $\bar{\phi}^2$ and $\bar{\phi}$ from $(\bar{\phi}^2)$ and (ϕ) gives indeterminate fractions; but if we substitute from the equations just written, differentiate with respect to x , and afterwards make $x = y$ in the usual manner, we have the following values of $\bar{\phi}^2$ and $\bar{\phi}$.

$$\bar{\phi}^2 = \bar{\alpha}x - \bar{\beta}x \frac{\bar{\alpha}'x}{\bar{\beta}'x} \cdot \frac{F'_0 \bar{F} - A'_0 \bar{A}}{F'_0 \bar{F} - B'_0 \bar{B}}$$

$$\bar{\phi} = -\frac{\bar{\alpha}'x}{\bar{\beta}'x} \frac{F'_0 \bar{F} - A'_0 \bar{A}}{F'_0 \bar{F} - B'_0 \bar{B}};$$

where F'_0 means the differential coefficient of $F(x-y)$ with respect to x , for the particular value $x = y$, and $\bar{F}x$ is the modulus of $F(x, y)$; and the same for the rest. And F'_0 , &c. may be severally zero, if their vanishing ratios be substituted. Taking, therefore, $\bar{\phi}$ a solution of the modular equation, which makes the above-mentioned equations consistent, we must determine $\bar{F}$ from the second, giving any value we please to F'_0 . The two equations with which we set out then agree, and we have for every form of $\bar{\phi}$ an arbitrary function in the zero-function ϕ^0 ; but we thus only determine the modulus $\bar{F}$, and must afterwards find its zero-function. When $\bar{A} = \bar{B}$, and $A'_0 = B'_0$, we must suppose $\bar{F} = \bar{A}$ and $F'_0 = A'_0$, unless it so happen that $-\frac{\bar{\alpha}'x}{\bar{\beta}'x}$ is a solution of the modular equation, in which case $\bar{F}$ and F'_0 may be any whatsoever.

(314.) The solution just mentioned, and its consequence, arises from the following identical equation:

VOL. II.

$\int \phi x \cdot \phi'' \phi x \cdot \phi' x \cdot dx = \phi' \phi x \cdot \phi x - \phi^2 x$, which reduces every direct question of integration to the solution of the functional equation

$$\phi x \cdot \phi' x \cdot \phi'' \phi x = \alpha x.$$

(315.) All the conditions which depend on moduli being now satisfied, we must assume such a value of $F(x-y)$ as will reduce F'_0 to the value we suppose it to have in determining $\bar{F}$, and must then substitute

$$\frac{x+y}{2} + F \cdot \bar{F} \bar{F}^0$$

in the original equation. All is here known, except $\bar{F}$, which must be determined from the equation, and the result will enable us to give a solution; being, in effect, like the latter part of the process first given. A trial of this process will make it appear that we have no method of obtaining a solution to any given zero-function.

(316.) The equation

$$\bar{\phi}^2(x, y) = -x^2 y + 2xy \phi(x, y)$$

gives the modular equation

$$\bar{\phi}^2 x = -x^4 + 2x^2 \bar{\phi} x,$$

which is satisfied by

$$\bar{\phi} x = cx^2, \quad c^3 = 2c - 1,$$

and by

$$\bar{\phi} x = x^2 - 1.$$

The first gives the solution

$$\phi(x, y) = \frac{c^2 xy + c \sqrt{c^2 x^2 y^2 - (2c - 1)x^3 y}}{2c - 1};$$

the second gives

$$\phi(x, y) = xy - \sqrt{x^2 y^2 - x^3 y + 1}.$$

(317.) Among the cases of equations which are reducible to those we have considered, we may instance

$$\frac{\phi(\alpha, \beta) \frac{d\alpha}{dx} + \frac{d\beta}{dx}}{\phi(\alpha, \beta) \frac{d\alpha}{dy} + \frac{d\beta}{dy}} = \phi(x, y),$$

α and β being any functions of x and y . This is the most general equation with which we are acquainted that does not contain differential coefficients of unknown functions. Assume any function whatsoever, γz , and solve the equation

$$\psi(\alpha, \beta) = \gamma \psi(x, y), \text{ then } \phi(x, y) = \frac{\frac{d\psi}{dx}}{\frac{d\psi}{dy}}$$

is a solution of the given equation, as is sufficiently evident.

(318.) We shall now proceed to consider the formation of successions of partial substitutions, denoted by

$$\psi_{1,2}^{m,n}(x, y) \quad \psi_{2,1}^{m,n}(x, y), \text{ \&c.}$$

If we consider (the order of the letters being always that of operation, unless the contrary be denoted by underwritten numerals)

$$\phi^{2,1}(x, y) = \phi(\phi(x, y), y),$$

it appears that the modulus of $\phi^{2,1}(x, y)$ is $\phi(\bar{\phi}x, x)$. Similarly, the modulus of $\phi^{1,2}(x, y)$ is

$$\phi\{\phi(\bar{\phi}x, x), x\};$$

or if $M\phi^{n,1}$ be the modulus of $\phi^{n,1}$, we have

3 D

Calculus of
Functions.

we have also

$$M \phi^{n+1,1} = \phi (M \phi^{n,1}, x);$$

$$M \phi^{n+1,1} = \phi^{n,1}(\bar{\phi} x, x),$$

in which latter function n and 1 refer to $\bar{\phi} x$ and x .

If ϕx be itself a zero-function, it is evident that the modulus is and remains equal to x , or all successive functions of zero-functions are zero-functions.

(319.) The application of the preceding methods to equations involving partial substitutions would be of little use, and all that has been done on this subject amounts to the partial solution of a few equations of the most simple character.

But the preceding methods may be made useful in giving some idea of the difficulties which stand in the way of obtaining solutions.

Let us take the following equation, considered by Mr. Babbage:*

$$\phi^{2,1}(x, y) = \phi^{1,2}(x, y) \text{ or } \phi\{\phi(x, y), y\} = \phi\{x, \phi(x, y)\};$$

writing $\bar{\phi} \phi^0$ for ϕ , we find this is satisfied when $y = x$, by

$$\phi^0(\bar{\phi} x, x) = \phi^0(x, \bar{\phi} x),$$

which, being true for all values of x , must be true if we substitute ϕ^0 for x , which gives

$$\phi^0(\phi, \phi^0) = \phi^0(\phi^0, \phi);$$

or we must have a function, which is a symmetrical function of itself, and of a function of itself.

The several conditions here deduced can be easily satisfied, but we have not met with any method by which a particular solution can be found. Any zero-function, for instance, satisfies the two last-mentioned equations. And, if any solution can be found, any derivative of it is also a solution. But we have not succeeded in determining any solution.

The interchange of x and y in the preceding does not alter the problem; from which it should seem that the function in question must be symmetrical.† But, in this case, the question is reduced to assigning $\phi(\phi(x, y), y)$, so as to be equal to $\phi(\phi(y, x), x)$, or making $\phi(\phi, y)$ symmetrical. Now it is easy to see that this cannot be where ϕ is already symmetrical; for it gives $\phi(\phi, y) = \phi(\phi, x)$, which cannot be generally true, but assigns an equation of condition between y and x . This reasoning is not, as Mr. Babbage remarks, of a very sure character, but it furnishes a strong presumption that all the solutions of the given equation are discontinuous.

(320.) We shall now conclude with some forms in which particular solutions have been obtained.‡

Let

$$x \phi^{1,2}(x, y) = y \phi^{2,1}(x, y).$$

Assume

$$\phi = \theta \alpha(\theta^{-1}x, \theta^{-1}y),$$

which gives

$$\theta x \cdot \theta \alpha^{1,2}(x, y) = \theta y \theta \alpha^{2,1}(x, y),$$

which is satisfied if

$$\alpha^{1,2}(x, y) = y \quad \alpha^{2,1}(x, y) = x;$$

that is, we have to find a function which is periodic of the second order, both with respect to x alone and to y alone. Take any periodic function of the second order, which contains one or more arbitrary constants, being a function of x , and assume the arbitrary constants such

functions of y as will make the periodic function in question symmetrical. For instance, $\frac{a-x}{1-bx}$ being a periodic function of the second order, for a write $a-y$, and for b write by , and we have the solutions

$$\frac{a-x-y}{1-bxy}, \text{ and } \theta\left(\frac{a-\theta^{-1}x-\theta^{-1}y}{1-b\theta^{-1}x\theta^{-1}y}\right),$$

but (70.) we cannot thus obtain any form which contains more than $\theta(a-\theta^{-1}x-\theta^{-1}y)$.

The same solutions will also satisfy

$$\phi^{1,2}(x, y) \times \phi^{2,1}(x, y) = xy,$$

and generally (F being given)

$$F(x, \phi^{1,2}(x, y)) = F(\phi^{2,1}(x, y), y)$$

(321.) Let

$$F(\phi^2(x, y), x) = F(a, \phi^{2,1}(x, y)).$$

Assume $\phi = \theta \alpha(\theta^{-1}x, \theta^{-1}y)$, which gives

$$F(\theta \alpha^2(x, y), \theta x) = F(a, \theta \alpha^{2,1}(x, y)),$$

and is satisfied by $\theta \alpha^2 = a$, $\alpha^{2,1}(x, y) = x$.

Take any periodic function with an arbitrary constant, and substitute for the arbitrary constant such a function of y as will give the resulting function a constant modulus c : then assume $c = \theta^{-1}a$. For instance, take

$$\frac{m-x}{1-nx}, \text{ write } m+y \text{ for } m, \text{ and } \frac{n}{y} \text{ for } n, \text{ which gives}$$

$$\frac{(m+y-x)y}{y-nx}, \text{ whose modulus is } \frac{m}{1-n} = \theta^{-1}a.$$

Hence $\theta\left(\frac{(1-n)\theta^{-1}a + \theta^{-1}y - \theta^{-1}x}{\theta^{-1}y - n\theta^{-1}x} \theta^{-1}y\right)$ is a solution.

(322.) Let $F(x, y, \psi, \psi_1, \psi_2, \dots) = 0$; ψ, ψ_1, ψ_2 , &c. being all some successive functions of ψ or $\psi(x, y)$. The assumption $\psi(x, y) = \theta \alpha(\theta^{-1}x, \theta^{-1}y)$ reduces the preceding to

$$F(\theta x, \theta y, \theta \alpha, \theta \alpha_1, \theta \alpha_2, \dots) = 0,$$

α_1, α_2 , &c. being the corresponding successive functions of α .

Assume any given form for α , and the equation is reduced to one containing one unknown function θ . For each form of α the equation may or may not possess a solution. And, even if $\alpha(x, y)$ be a particular solution of the equation, it does not follow that θ contains an arbitrary function.

(323.) The difficulty of the preceding species of solution is this, that, when we have obtained the final equation, we have no direct means of referring it to the solution of an equation with functions of one subject, except upon two considerations, neither of which will apply. Firstly, the equation may be simplified if α, α_1 , &c. have the same zero-functions, which will not be the case. Secondly, if we take a particular form of α , and solve the equation with respect to either x or y , considering the other as an arbitrary constant, we shall obtain solutions containing the supposed arbitrary constant in a manner which requires that we should actually consider it as such, so that we cannot obtain a final result which remains true when the temporary arbitrary constant undergoes the given changes. To take a case, let us again propose the equation

$$\phi^{2,1}(x, y) = \phi^{1,2}(x, y),$$

and let us suppose $\phi(x, y) = \theta(\theta^{-1}x + \theta^{-1}y)$. This gives

$$\theta(\theta^{-1}x + 2\theta^{-1}y) = \theta(2\theta^{-1}x + \theta^{-1}y),$$

Calculus of or
Functions.
or

$$\theta(x+2y) = \theta(2x+y),$$

$$\theta x = \mu \cos 2\pi \frac{\lambda(x-3y)}{\lambda 2},$$

considering y as an arbitrary constant. If we distinguish y when it comes from the supposition $\phi(x, y) = \theta(\theta^{-1}x + \theta^{-1}y)$ from y as it appears in the preceding solution, so as to suppose y to be lineally (266.) changed with respect to the manner in which it thus enters in forming $\phi^{1,2}(x, y)$, we can obtain a solution: but such is not the case supposed.

(324.) Since we have separated the considerations connected with $\phi(x, y)$ into 1. those which relate to its zero-function, 2. those which relate to its modulus; and since it appears that problems may be possible so far as one of the two is concerned, and not possible with respect to the other, we shall propose some questions in which one only of the preceding two is concerned. Suppose, for instance, it is required to find those functions in which $\phi^{m,1}(x, y)$ has a constant modulus. If we take the case of $m=2$, we have

$$\bar{\phi}^0(\bar{\phi}x, x) = \bar{\phi}^{-1}c,$$

c being the given constant. If then we assume any zero-function, we may determine $\bar{\phi}x$ in terms of x and $\bar{\phi}^{-1}c$.

Thus in the case of $\bar{\phi}^0(x, y) = \frac{1}{2}(x+y)$, we find

$$\bar{\phi}x = 2\bar{\phi}^{-1}c - x \quad \phi(x, y) = 2c - \frac{x+y}{2},$$

which satisfies the conditions. And our being thus able to determine one modulus only to a given zero-function, shows that problems, in which both are left indeterminate, will probably be of very limited solutions.

(325.) Let the modulus of $\phi^{m,n}$ be denoted by $\bar{\phi}^{m,n}$, and let the equation be

$$\bar{\phi}^{2,1}(x, y) = \bar{\phi}^{1,2}(x, y).$$

The zero-function is now arbitrary, and as in (319.) we find

$$\bar{\phi}^0(\bar{\phi}x, x) = \bar{\phi}^0(x, \bar{\phi}x),$$

and our solution is this, that the function may either be a zero-function itself, or its modulus may be any invertible solution of $f(x, y) = f(y, x)$: for the preceding equation gives $\bar{f}\bar{\phi}^0(x, y) = \bar{f}\bar{\phi}^0(y, x)$. Thus by solving the equation

$x^2 + y = y^2 + x$, we have $y = 1 - x$, and the zero-function in question is derived from

$$x^2 + z = x^2 + y, \text{ giving } z = -\frac{1}{2} + \sqrt{x^2 + y + \frac{1}{4}},$$

so that the function required is

$$\phi(x, y) = \frac{3}{2} - \sqrt{x^2 + y + \frac{1}{4}},$$

which will be found to satisfy the condition; namely, that the modulus of $\phi^{2,1}(x, y)$, or of

$$\frac{3}{2} - \sqrt{\frac{11}{4} + x^2 + 2y - 3\sqrt{x^2 + y + \frac{1}{4}}},$$

is the same as that of $\phi^{1,2}(x, y)$, or of

$$\frac{3}{2} - \sqrt{x^2 + \frac{7}{4} - \sqrt{x^2 + y + \frac{1}{4}}}.$$

So long as a condition between moduli only is given, leaving the zero-functions indeterminate, the question is frequently reduced to one of ordinary algebra: but when the modulus is given, and the zero-function is to be found, the question is reduced to one of the species solved in (309.)

(326.) Required the function as to which the result is the same, whether we differentiate with respect to x or change y into αy : that is, which gives

$$\phi(x, \alpha y) = \frac{d}{dx} \phi(x, y).$$

Assume

$$\phi(x, y) = \mu y e^{\nu y \cdot x},$$

which gives

$$\nu \alpha y = \nu y \quad \mu \alpha y = \mu y \cdot \nu y \dots (\mu, \nu),$$

by the first of which it appears that the second may be solved as if νy were constant. This gives

$$\nu y = \xi \alpha y \quad \mu y = (\xi \alpha y)^{-A y},$$

where $A y$ is the exponential inverse of αy . Hence we have

$$\phi(x, y) = \sum \{ (\xi \alpha y)^{-A y} e^{\xi \alpha y \cdot x} \}.$$

When the function αy is periodic, (μ, ν) cannot be both solved continuously, unless $(\alpha^n x = x)$,

$$\nu x \cdot \nu \alpha x \dots \nu \alpha^{n-1} x = 1, \text{ or } (\nu x)^n = 1,$$

which gives

$$\xi \alpha x = r^p (r^n = 1)$$

$$\phi(x, y) = \sum \{ (y + r^p \alpha y + \dots + r^{(n-1)p} \alpha^{n-1} y) e^{r^{-p} x} \},$$

or, more generally,

$$\phi(x, y) = \sum \{ \xi \alpha y (y + r^p \alpha y + \dots + r^{(n-1)p} \alpha^{n-1} y) e^{r^{-p} x} \}.$$

(327.) Mr. Babbage has reduced the preceding to a differential equation, when $\alpha^n y = y$, as follows: the first of these equations gives all the rest.

$$\phi(x, \alpha y) = \frac{d}{dx} \phi(x, y) \quad \phi(x, \alpha^2 y) = \frac{d}{dx} \phi(x, \alpha y) \\ \dots \dots \dots \phi(x, y) = \frac{d}{dx} \phi(x, \alpha^{n-1} y)$$

whence

$$\phi(x, y) = \frac{d^n}{dx^n} \phi(x, y),$$

from which the same solution may be obtained.

By similar methods, the equation

$$\frac{d}{dx} \phi(x, \beta y) = \frac{d}{dy} \phi(\alpha x, y)$$

may be reduced to a partial differential equation, when αx and βy are periodic of the same order. The general solution of this case is of considerable difficulty, if indeed it be practicable.

(328.) A functional equation may admit of reduction to one of a more simple form, if it can be seen that a solution is derived, by supposing one function of the unknown forms to undergo no change, when another function of the same is substituted. Such is the equation belonging* to the class of curves which have the ordinate and the normal drawn from the same point in the axis of abscissæ, equal to each other. It is

$$(\phi x)^2 + \left(\phi x \frac{d\phi x}{dx} \right)^2 = \left(\phi \left(x + \phi x \frac{d\phi x}{dx} \right) \right)^2;$$

* Euler, cited by Babbage, *Essay*, &c., part ii.

Calculus of
Functions.

by differentiating which, it will be seen that $\phi x \frac{d\phi x}{dx}$

does not change when $x + \phi x \frac{d\phi x}{dx}$ is substituted for x . This leads to the equation

$$y^2 = xy \frac{dy}{dx} + \phi \left(y \frac{dy}{dx} \right).$$

The connection between differential and functional equations might be advantageously examined by means of such equations, but we have already gone beyond the limits which we had prescribed to ourselves in setting out.

Remark alluded to in (48.) The reason why we may suspect that any general form, which contains all the *whole* functions, may also contain, at least, some fractional ones, lies simply in our perfect ignorance of the general form of $\phi^n x$. We see in (70.) that one purely arbitrary method of representing a whole function, gives results entirely agreeing with those which are derived from a more legitimate deduction of form; and this, even in cases where no fractional functions, or functional inverses, can be obtained from the same representation of $\phi^n x$. In making the extension on which this remark is written, we have still, in our representation of $\phi^n x$, preserved the condition $\phi(\phi^n x) = \phi^{n+1} x$, which is the definition of $\phi^n x$. If, then, we find no functional inverses among the forms so obtained, that we cannot do so can only be a result of observation of some particular cases; and the smallness of the number of forms to which we can apply observation, together with the results of (153.) and (154.), and the infinite number of

forms which we are able to give to $\phi^n x$, when $\phi x = x$, must (even taking into account any presumption to be derived from the observations in (158.), oblige us to pause before we assume the most simple method of representing $\phi^n x$ in terms of n , as the proper general expression, even in the case where n is a whole number.

Addition to Article (26.) The invention of what we may call primary or fundamental notation has been but little indebted to analogy, evidently owing to the small extent of ideas in which comparison can be made useful. But at the same time analogy should be attended to, were it for no other reason than that, by making the invention of notation an art, the exertion of individual caprice ceases to be allowable. Nothing is more easy than the invention of notation, and nothing of worse example and consequence than the confusion of mathematical expressions by unknown symbols. If new notation be advisable, either permanently or temporarily, it should carry with it some mark of distinction from that which is already in use, unless it be a demonstrable extension of the latter. For this reason, had the separation of functional symbols in (22.) occurred often, we should have proposed to write $[\phi + \psi] x$ instead of $(\phi + \psi) x$.

The mathematical parts of a work may be divided into two species: firstly, the verbal explanations which accompany the passage from step to step; secondly, the actual expressions themselves. In the first, there are circumstances of convenience or inconvenience which are not of the same, or even of an opposite character, when considered with respect to the second. We think the frequent use of $>$, $=$, and $<$ in the first as rather injurious to what is there required, namely, the consideration of the different clauses of an assertion with respect

to their mutual relation in reasoning, though of course highly convenient when the whole of an expression is to be considered rather as to what is obtained than as to how it has been obtained. But the power of the printer's types is also to be considered in the first part, though not in the second, and the following suggestion is made on a circumstance which is of considerable consequence in the printing of mathematical works

The occurrence of fractions, such as $\frac{a}{b}$, $\frac{a+b}{c+d}$, in the

verbal part of mathematical works is a source of considerable loss of room, and creates an inelegant and even confused appearance in the printed page. It is very desirable, in every point of view, except the strictly mathematical one, that some method of representation should be adopted which does not require a larger space than is usual between two successive lines. At the same time, it is by no means of very great importance that the verbal part should entirely coincide with the mathematical part in notation, so long as the latter remains to preserve the usual conventions. The symbol $\div$ has been disused for a sufficient reason, namely, the number of times which the pen must be taken off to form it. This has been, and we imagine always will be, the cause either of abandonment or abbreviation. The question is, whether a new and easy notation could not be substituted; and it is desirable that it should be derived from analogy, such as (accidentally, we believe) does exist in $>$, $=$, and $<$. If we look at $\times$ and $+$, and observe that the first is made by turning the second through half a right angle, denoting multiplication, which is primarily an extension of addition in like manner as division is an extension of subtraction, we may thus invent the symbol $/$ or $\setminus$ to denote division, which is also the symbol of subtraction turned through half a right angle. If a/b were used to denote a divided by b , and $(a+b)/(c+d)$ to denote $a+b$ divided by $c+d$, all necessity for increased spacing would be avoided; but this alteration should not be introduced into completely mathematical expressions, though it would be convenient in particular cases.

A complicated exponent might be avoided by the use of the symbol λ^{-1} . The student would soon learn to consider $\lambda^{-1} \{ (a+bx)/(c+ex) \times \lambda a \}$ as meaning the same thing as

$$\frac{a+bx}{a^c+ex}.$$

If, in the course of investigation, some plan of this kind be not adopted, the expense of printing will place a limit to analysis. A work entirely devoted to the consideration of such expressions as the preceding might easily be doubled in size and price by the frequent occurrence of them in the text, or else rendered confused and unintelligible by successive abbreviations. Considering, however, that λ is an inverse symbol in the sense of (124.), and λ^{-1} a direct one, it would, perhaps, rather be advisable that some method of denoting an exponent should be adopted which does not raise the exponent above the symbol of the root. Either of the following might be proposed, the defect of them all being that they are not derived from analogy:

$a \wedge \{ (a+bx)/(c+ex) \}$ $a : \{ (a+bx)/(c+ex) \}$, or the like. But we do not advocate the introduction of these into purely symbolical expressions, any more than in the former case.

Addition to Article (185.) In common differential

Calculus of
Functions.

Calculus of Functions. equations, the arbitrary constant may have a discontinuous value. Take any arcs which join each other from different individual curves of the species $y = \psi(x, c)$, and the broken curve so formed is in every respect a solution of the differential equation, even at the points of union, where it may be supposed to have a discontinuous tangent. As the phrase "solution of a differential equation" may contain matter of opinion, and even of convention, we state that we mean by the solution of $F\left(x, y, \frac{dy}{dx}\right) = 0$ simply this: any line whatsoever, such, that if any values a and $a + h$ be taken for x , giving b and $b + k$ for y , the expression $F\left(a, b, \frac{k}{h}\right)$ may be made as small as we please by taking a sufficiently small value of h . This appears to us nothing more than the rejection of intermediate definitions, and the statement of the conditions in terms of fundamental notions; and,

if we are right in saying this, then it certainly follows that the constant may be discontinuous. By diminishing the intervals of continuity without limit, we get for a limit the curve whose equation is the *particular solution* of the equation in question; but which might be called the *limit of the discontinuous solutions*.

The same might be extended to the case of partial differential equations and their surfaces, by making the arbitrary functions discontinuous. If the representation of a discontinuous solution be made, the intervals of discontinuity determined, and then diminished without limit, the value of the discontinuous constant is then of the form $f(a)$, where a is the value of x at the last epoch of discontinuity. The diminution of the interval of continuity will then be found to require a process for the determination of the constant, which amounts to differentiating the original equation with respect to that constant, and eliminating in the usual way.

- (102.) Solution of $\phi ax = \phi x$:—
1. If $\phi^n x = \mu (\cos 2\pi n)$ and $\phi^n y = \nu (\cos 2\pi n)$ give $n = Ax$ and $n = By$ then $\phi x = B^{-1}Ax$ solves $\phi ax = \phi x$.
 2. If $\phi^n x = c$ give $n = Ax$, then $Aax = Ax - 1$ and $\xi ax = \nu (\cos 2\pi Ax)$.
- (103.) Solution of $\psi ax = \psi x$.
Solution of $\psi ax = \psi x + c$ and $\psi ax = (\psi x)^c$.
- (104.) Ax called the *exponential inverse* of ax . Deduction of exponential inverses of the derivatives of ax .
- (105.) On the equation $Aax = Ax + m$.
- (106.) Application to $a + bx$ and $a + x$.
- (107.) Application to $(ax)_b$ and ax .
- (108.) Application to the two forms of $\frac{a+bx}{a'+b'x}$.
- (109.) Application to the derivatives of ax .
- (110.) Connection with preceding results.
- (111.) Application to a case of $a + bx + cx^2$.
- (112.) Recapitulation of derivative forms for which $\phi ax = \phi x$ can be solved.
- (113.) Determination of $\phi^n x$ from Ax .
- (114.) Convertibility of successive functions.
- (115.) Application to finding functions convertible with a given function.
- (116.) Extensive class of algebraical functions which are convertible.
- (117.) Determination of a function which is changed in a given manner, by simultaneously changing x_1 into $a_1 x_1$, x_2 into $a_2 x_2$, &c. Want of generality of the solution.
- (118.) Example and remarks.
- (119.) Extension of the form of ξax .
- (120.) Reason for supposing the simultaneous equations $\phi ax = \phi x$, $\phi \beta x = \phi x$ to be generally insoluble with existing forms.
- (121.) Want of a process for the above analogous with one of algebra.
- (122.) Case in which the above admits of general solution.
- (123.) Meaning of the word *transcendental*; remarks on the progress of transcendentals.
- (124.) Direct and inverse functions.
- (125, 126.) Different methods of forming functional equations.
- (127, 128.) Remarks on their transcendentals.
- (129.) Exponential inverse of periodic functions of the second order, and reduction of $\xi \phi x$ thus obtained to the form in (86.)
- (130.) Extension to periodic functions of higher orders.
- (131, 132.) Methods of changing functional equations into others, by substituting functions of x for x , and also by destroying a known term by means of a particular solution.

- (133.) There cannot be two particular solutions of $\phi ax = \beta x + \phi x \gamma x$ independently of ξax . See also (176.)
- (134.) Except where ax is periodic there is one general *algebraic* solution of the preceding.
- (135.) Method of destroying the known term of a general functional equation of the first degree.
- (136.) Method of obtaining a particular solution, where the known functions are successive functions of a periodic function.
- (137.) Solution of $\phi ax = \beta x + \phi x \gamma x$, where $\phi^n x = x$.
- (138, 139.) Cases in which an arbitrary function enters the solution.
- (140.) Solution of $\phi ax = c \phi x + c'$ and instances.
- (141.) Solution of $\phi ax = \phi x + c'$.
- (142.) Solution of $\phi(x^b) = p x^m \phi x$.
- (143.) Solution of $\phi^n x = \frac{d^m \phi x}{dx^m}$.
- (144.) Definition of *compound* functions and *converse* functions.
- (145.) Given the results of a compound operation of the second order and of its converse, required the operations themselves; solution of $\phi \psi x = \cos a \cos^{-1} b$ $\psi \phi x = \cos b \cos^{-1} a$.
- (146.) Solution of $\phi \psi x = \theta \alpha \theta^{-1} x$ $\psi \phi x = \theta \beta \theta^{-1} x$.
- (147.) Solution of $\phi \psi x = ax$, $\psi \phi x = x^b$.
- (148.) Deduction of the solution of $\phi_{-1} \phi x = ax$.
- (149.) The same method applies to finding convertible functions.
- (150.) Determination of a function which is inverted with respect to one variable by the interchange of two others.
- (151.) Converse functions are simple derivatives of each other.
- (152.) $\phi^n x = ax$, distinction between it and $\phi^n x = x$.
- (153.) Extensions of particular solutions of $\phi^n x$ by use of general forms of ax . Example, $\phi x = x^a = ax$.
- (154.) Another example, $\phi x = \tan 2 \tan^{-1} x$.
- (155.) Method by which arbitrary functions might be supposed to be introduced, and remarks.
- (156.) General method of solving $\phi^n x = a^x x$ shown to lead to the method of (113.)
- (157.) Indefinite expression for $a^{\frac{1}{n}} x$ by means of the exponential inverse of x .
- (158.) Conditions of verification of the preceding.
- (159.) $\phi^n x = ax$, where ax is periodic.
- (160.) Method for $\phi^n x = a^n x$.
- (161.) Deduction of successive functions as derivatives of each other and of their functional inverse. Connection between the deriving functions in the two cases.
- (162.) Mr. Babbage's method of finding $\phi x = \xi ax = \xi \beta x$.
- (163.) Difficulties in the way of its application. Its failure when convertible inverses only are employed.
- (164.) Application to the case of $\phi x = \xi m x = \xi n x$. Ambiguity of the solution deduced. Reason why there can be no direct and unambiguous solution.
- (165.) Application to $\phi x = \xi x^m = \xi n x$.
- (166.) General method of the last two instances.
- (167, 168.) Solution of the problem in the case of periodic convertible functions.
- (169.) General insolubility in other cases.
- (170.) Solution of $(\psi a)^2 \psi \beta x a = \gamma x$.
- (171.) Method of obtaining periodic functions.
- (172.) Solution of $a_1 x \phi_1 x + a_2 x \phi_2 x + \dots = \gamma x$ with rational forms of $\phi_1 x, \dots$, when $a_1 x \div \gamma x, \dots$ are rational.
- (173.) Solution of $\psi a(x, \psi x) = x$.
- (174.) Solutions of $F(x_1 \psi x, \psi^2 ax, \dots) = 0$.
 $F(x_1 \psi x, \psi^2 x, \dots) = 0$.
and remarks upon the character of the solution.
- (175.) Direct reduction of a functional equation to an equation of differences by means of the exponential inverse.
- (176.) Process of solution of $\phi x + \beta x \phi ax = \gamma x$. Only one arbitrary function can enter the general solution.
- (177.) There may be in appearance more than one algebraical form of particular solution.
- (178.) There may be an infinite number of discontinuous solutions. Method of forming them.
- (179.) The arbitrary constant of the equation may be discontinuous.
- (180.) Remarks on the arbitrary constant.
- (181.) Conditions of the discontinuous constant.
- (182.) Application to some examples.
- (183.) *Single values* of the discontinuous constant.
- (184.) Remarks on developement into series.
- (185.) Developements represented by functional equations. A discontinuous constant may enter an equation of finite differences. See remark at the end on differential equations.

THEORY OF PROBABILITIES.

Theory of
Pro-
babilities.

(1.) IF it had been our only view to write a Mathematical Treatise on the Theory of Probabilities, in the common sense of the word, we might at once have proceeded to lay down the leading principles of the science. But we have a prior duty to perform, arising out of the various opinions which are held, even by mathematicians, upon the nature of this subject and the extent to which it is to be considered as a guide to truth. No part of mathematics or mathematical physics involves considerations so strange or so difficult to handle correctly, and there is no subject upon which opinions have been more freely hazarded by the ignorant, or rational dissent more unambiguously expressed by the learned. One, an amusing and popular writer, but all whose works put together do not, from the nature of his subjects, necessarily imply an acquaintance with so much as the four rules of arithmetic, calls it, from his own stores of knowledge, an "elaborate delusion;" a second, a mathematico-physical writer of the first character, while he appears to value the results* of the theory, seems not convinced by their evidence. If we appear severe in calling attention to the maxim of Horace,

Theory of
Pro-
babilities.

Intererit multum, Davus ne loquatur, an heros,

we consider that we are justified, with respect to the former writer, by his presumptuous opinion upon an unstudied science; and with respect to our subject, by the necessity of making it clear that we do not intend these preliminary observations as an answer to every objector, but to those whose knowledge places them above that position, *inter Davum et heros*, at which the formation of an independent opinion begins to deserve respect.

At the outset, we concede this point,—that no *primary* considerations connected with the subject of *probability* can be or ought to be received if they depend upon the results of a complicated mathematical analysis. The latter, if it be any thing else but an abbreviator of operations, is indeed an "elaborate delusion," and has often been made such: for instance, by an earlier school of writers on astronomy, who contended that the form of a planet's orbit should be *deduced* from geometry only. But the concession will not amount to much; for it would equally be made to a person who was desirous of knowing the number of cannon balls in a square pyramid of 50 rows high. All the mathematics in existence will teach no more about the number in the pile than can be found by counting; and if the latter should be preferred to a rule by a man who felt no assurance of the truth of algebra, a mathematician who stood by, while he admitted the propriety of not trusting an unknown science, would congratulate himself that he could certainly know how (by taking one-sixth of the product of 50, 51, and 101) to produce the result in a minute which would cost the other an hour. But if he who counted called algebra a delusion, he would not the less deceive himself because it is possible to do without algebra.

(2.) If, upon very simple and obvious principles, we can show that a certain problem about ten subjects requires the multiplication of all whole numbers up to ten, and so on, it will be equally clear as to principle that the same problem in the case of ten thousand subjects will require the multiplication of all the whole numbers up to ten thousand; and it will at once be decided that the first is within the compass of a reasonable industry, and that the second is not. But this decision will not be correct; for the higher branches of mathematical analysis show a method of finding, not exactly but approximately, the continued product of all numbers up to any given limit, with very little trouble. That is, suppose the product were really

2376948 (with 10,000 intervening digits) 16432,

it would be easy to find, as a mathematical approximation,

2376948 (with 10,000 intervening ciphers) 00000

the second of which, though it differ enormously from the first, does not differ from it by a millionth part of itself; or, if money were the thing in question, by the tenth part of a farthing upon a hundred pounds. This will be sufficient for practical applications, and every reader may now see in what way the higher branches of mathematics are concerned in our present subject. They are the abbreviators of long and tedious operations, and it would be perfectly possible, with sufficient time and sufficient industry, to do without them in every case.

The preceding consideration naturally divides the subject into two parts. In the first, we have to consider first principles and easy applications: in the second we have to apply to *the same first principles* the heavy artillery of mathematical analysis, in the case of problems which involve large numbers. We shall therefore proceed at once to the consideration of the first principles.

(3.) The word *probable*, as commonly applied to a coming event, indicates many different degrees of that feeling with which the mind looks at the prospects of the future, and which depends upon the habits derived from looking at the past. Mark the impression which the two following assertions produce upon the mind—"The sun will not rise to-morrow," and—"The sun will rise to-morrow." The first is so excessively improbable as to be practically absolutely deniable; and the second approaches so near to certainty as to admit of positive affirmation. Take any third assertion, and compare it with the preceding two as to the effect it produces;

* "I will not undertake to say that I think the method of *minimum squares* is unexceptionable in all its applications, or that I attach much more than a relative value to the estimation of *probable errors*. But I think there is no doubt that these methods have contributed much to the accuracy of modern astronomy, &c."—*Rep. Brit. Assoc.* vol. i. p. 165.

Theory of
Pro-
babilities.

if it be such as we should incline to class with the first, rather than the second, we at once call it improbable. If we should rather class it with the second, we call it probable. If we are in doubt which to do, we say it is neither probable nor improbable. These words do not apply to any thing in the event itself, but to a state of mind produced by its contemplation; which must be remarked, because it is at once the answer to many objections, particularly those of a religious character. The theory of probabilities has been sometimes asserted to refer to chance the settled plan of God's providence, so that it cannot reasonably apply except on the supposition that events happen by chance. This entirely proceeds on the notion that we are looking at the event itself that is to come, and considering its probability as a kind of quality which it possesses, in the same sense as matter is said to possess extension, weight, &c. Now even if we granted the well-known theory of Berkeley, and referred all these qualities to the mind, even then we say that we must refer the notion of *probability* to the mind of the observer in a closer degree, as being one which belongs to subjects on which the knowledge and habits of individuals make differences. Take Berkeley's theory for granted, and carry two men to a room in which are two boxes, one small and ribbed with steel, the other large and roughly put together. Let these men have come from the two most opposite points of the earth in manners and customs, yet they will immediately, when asked, point out which is the larger of the two boxes: if they are both sane, disagreement will be impossible. Now produce a piece of gold, and ask which of the two boxes is filled with that substance. One has seen gold, and knows its value, and also that it is rarely collected in large quantities, or placed in insecure receptacles. He would say that most likely the smaller box, if either, is full of gold. Or he may think that the question and circumstances are so extraordinary, that the former would not have been put unless this case had been a departure from ordinary rules, and may therefore pronounce for the larger box. In either case it is clear that the probability or improbability is the consequence of a state of his own mind, or of an impression existing in himself, in a sense which cannot be, in any view of the case, applied to the extension of the two boxes. If the other man knew nothing of gold, he would not be able to bring his mind to either of the preceding conclusions, in preference to the other. What we mean, then, by an event being probable or improbable, is this; that with regard to that event the mind of the spectator is in a state of disposition either to doubt or believe its happening; which evidently depends in no way upon the event itself, but upon the whole train of previous ideas and associations which the mind of the spectator possesses upon such circumstances as he thinks similar. Therefore it is wrong to speak of any thing being probable or improbable in itself. The same thing may be *really* probable to one person and improbable to another. And thus men may be justified in drawing different conclusions upon the same subject.

(4.) With regard to the question above mentioned, that the theory of probabilities makes events happen by *chance*, let us consider for a moment what chance is. In common phrase, it means that we see no reason why events should have happened one way rather than another. And, if this be chance, events *do* happen by chance, for they certainly do happen when we can see no reason why they should not have been otherwise. But if by chance be meant that events happen when there is no reason why they should have happened, it is soon shown that *the rejection of the notion of chance is absolutely necessary to every theory of probabilities*. A meets B in Cheapside to-day at ten o'clock; he says, I met B *by chance* to-day, by which he means that he can show no reason why B should not have been any where else. He meets B to-morrow at the same place and hour; he immediately begins to suspect that the meeting was not *the work of chance*, but that B must have some *reason* for being in Cheapside at that hour, which renders it *probable* that he will meet him again to-morrow. The very notion of probability only exists as attached to some cause why the thing should happen; it increases with our degree of belief in a cause, and finally becomes certainty when we know there is a cause.

Suppose a native of a foreign country in which there are no forms of trial, he himself not understanding English, were to spend a week in observing the process of one of our criminal courts. He would certainly be able to find out that upon the pronouncing of the words "guilty" or "not guilty" would depend whether the prisoner would be led away in custody, or allowed to go free. Perfectly convinced as he would be of the existence of a cause for all the ceremonial he saw, what guide would he have to determine the manner in which causes act, so as to infer the result in any particular case? It is to him a problem of *chance*, as opposed to the proper object of inference. But it is not a problem of *chance* as opposed to the result of order, or of cause and effect, for he sees enough to assure him that there are reasons, but not enough to determine what they are. He is exactly in the situation in which we stand with regard to many phenomena in the moral order of things.

The word *chance* has very often been confounded with *probability*, which is the only excuse for the preceding objection. To take an ambiguous and metaphysical word, without inquiring in what sense it is used, namely, *as opposed to certainty*, and to argue thereupon as if it entered *as opposed to Providence*, is a logic every way worthy of the opponents of the sciences: we commend their fairness in not using one to the destruction of another. If we use the word chance, it will be in a common signification, that of a very low degree of probability. "It is a *mere chance* that I go to-morrow, but I shall *probably* go the day after."

(5.) The notion of *probable* is one which admits of the relation of more or less. It is *more* probable that rain will follow a fall of the barometer than a rise, *much* more probable. So far every one admits; but to the question *how much* more probable, no immediate answer can be given. But this question must be answered before mathematical reasoning can apply. Magnitude, the object of possible mathematics, is that to which the terms more or less can be applied. But *actual* mathematics cannot be useful unless we can, having applied the term *one* to a certain quantity, proceed to ascertain whether another quantity ought to be called 2, 3, 4, &c., or any intermediate fraction. If we had the same sort of knowledge of mind that we have of matter, we might then know how to weigh the force of one impression against another, just as we might in such a case make a numerical comparison of the proportions in which two men possess moral qualities of any given kind. But this is above our reach, and if we attempt to submit any state of mind to numerical analysis, it must be by means of some external manifestation of the feeling; and let it be remarked that there must be at some point or other of the passage

Theory of
Pro-
babilities.

Theory of
Pro-
babilities.Theory of
Pro-
babilities.

a convention as to the method of measurement to be adopted. It may be concealed, but still it exists; it may be considered by one as dubious, by another as nearly certain, but still it cannot be denied to be one of that class of truths which, if admitted at all, must be admitted upon the species of conviction in our own mind, which comes from its own observations, according to one sect of metaphysicians, or from its own fundamental notions, according to another, without the possibility of receiving absolute demonstration.* For it is easier to decide upon the notion itself, in the sense in which the words strike us, than to find out whether he who would demonstrate it means the same thing by the words he uses as we do ourselves; to say nothing of any other difficulty.

The notion we mean is this; we assert and require it to be granted that the feeling of probability or improbability is of the same kind, whatever may be the event in question; that the probability we attach to one event, say a fact in history, *bears a ratio* to that which we attach to any other of another kind, say the gaining of a prize in a lottery. If we were to state to any person that an advantage depended upon his guessing correctly which was the greater, the distance from London to York, or the weight of St. Paul's, he would at once answer that the question was inconceivable, for that greater or less, which apply to one length against another, or to one weight against another, do not apply to a length against a weight. By going to that universal referee, abstract number, he could tell whether the *number* of tons in St. Paul's exceeds or falls short of the number of feet in the distance from London to York, and might make this the subject of a guess with a certainty of being either right or wrong. But if his ideas on the subject be clear, he would answer that he could neither be said to be right or wrong in declaring that the length in question was greater or less than the weight. And with regard to immeasurable subjects, he would answer in the same way; for instance, if he were asked which was the greater, the musical power of Handel, or the mathematical power of Lagrange. Grant that the former was ten times the average power of musicians, and the latter nine times that of mathematicians, and the relation of these abstract numbers suggests an answer; but put one concrete quality by the side of the other for comparison, and the answer will appear impossible.† But with regard to probability, or the state of mind which produces it, if we were empowered to put the following question, we conceive that there would be but one answer. "There are two events, one past and one to come, on neither of which are you in possession of total and mathematical certainty. The first is the execution of Charles I.; the second is the drawing of a white ball from an urn which contains one white and ninety-nine black balls. Choose one of these, and let your interest in any way depend on your deciding rightly the one you select: would you rather the safety of your life should depend upon your saying correctly whether Charles I. was or was not executed, or upon your drawing the white ball, and not one of the black ones?" Every one who could make his decision under these circumstances with satisfaction to his own mind, does *bonâ fide* admit what he meant he should admit, though the words in which he would state the principle might be different from ours. He judges the impressions produced on his own mind by different events, with reference to probability, proper objects of comparison, which he would make numerical comparison, if he knew how. And he would not call his answer a guess, but the result of a rational process. We might put a case of doubt, as for instance the executions of Charles I. and Lord Strafford, on which the decision would be, that no man would sleep less soundly if his life depended on answering rightly as to the truth of either. But if a sufficient authority were to assure him that one of the two executions was a total fiction, the difficulty he would be under to say which it was would be a proof of his thinking the probabilities of the two proper objects of comparison, and of a defect of means only to decide, not of power to use them if he had them.‡

(6.) But still this question remains as much unanswered as before,—How are we to measure and compare the impressions on our own minds made by different events? To this we answer as follows. In the first place, there are two distinct considerations, of which the preceding is only one. They are

1. *How are we to measure and compare the impressions made on our minds by different prospects?*
2. *What is the rational way of using such measures or comparisons when we have got them?*

It is evident that we are liable to mistake in answering both questions; we may use a right measure wrongly or rightly, and we may obtain a wrong measure, and use it either wrongly or rightly. The first is a psychological question, the second a mathematical one. Any given answer to the first may admit of dispute; there is no fear of mathematics failing us in the second. But among the objectors we find a class who have confounded the two

* We are of no sect of metaphysicians, at least not decidedly enough to make their opinions the basis of a science. If the language used in any part of this Treatise appear to favour one opinion or another, we take this opportunity of saying that we merely endeavour to represent phenomena, as they appear to us, in phrases generally used, and to which of course any theory may be applied.

† Observe that this is distinct from the question, which should we admire most? just as the question which cost most, the road to York, or the structure of St. Paul's? is answerable, and distinct from the one first put.

‡ The mathematician may say, that the certainty of any one event is a unit of its kind, and that the probabilities are abstract fractions of it; whence he may argue that we are only engaged upon the same sort of question as that of comparing a number of miles with a number of tons. If we concede this, which we have no objection to do, our distinction must be thus stated: that we are constantly in the habit of doing the first, whether we will or no, but not the second.

A distinguished writer says, "Numerical measures are applicable only to things which depend on time or space. By such elements, in such a mode, how are we to estimate happiness and virtue, thought and will? To speak of a formula with regard to such things would be to assume that their laws must needs take the shape of those laws of the material world which our intellect most fully comprehends. A more absurd and unphilosophical assumption we can hardly imagine. We conceive, therefore, that the laws by which God governs his moral creatures, &c." The italics are of our own making: and unless for "are we" we should read "is God," here is as direct an argument from privation of human power to privation of divine power as the forms of language will allow. And from the preceding sentence to our quotation (where the author is speaking of the possibility of the divine intelligence embracing the whole of the mechanics of the universe in one formula) it is obvious that our proposed alteration, or something like it, must have been meant. But this renders the whole a train of reasoning we cannot admit. Our answer to it would be contained in maintaining the following proposition: whenever the terms *greater* and *less* can be applied, there *twice*, *thrice*, &c. can be conceived, though not perhaps measured by us.

Theory of
Pro-
babilities.

questions, and have treated those who answered the second with disdain, upon arguments which prove that they thought it was the first which was attempted to be answered. This has happened particularly with regard to the speculations of Condorcet and Laplace upon the *mathematical* consequences of testimony. These objectors rank with those who dispute Kepler's laws because they cannot conceive attraction. But is it not evident that the second question, properly answered, closes up one source of mistake, whether the first be answered or no? How many, for example, of controversial writers on all subjects have comprehended that an inference from ten equally probable premises is not itself as probable as each of the premises. Because they did not know which was two and which was three, they have declined to admit that two and three make five.

Theory of
Pro-
babilities.

(7.) We shall now enter upon the first of the two questions. Seeing that the impression which a prospect produces upon our minds is the result of a large combination of circumstances, and that it is almost impossible for us even roughly to estimate the share which each takes in the united effect, our plan must be to make circumstances for ourselves, in which all collateral considerations shall be avoided in every case in which we have any reason to suppose they exert influence. Our object being, not to investigate circumstances themselves, but the effect they produce upon our disposition to doubt or expect, we shall invent the former and examine the latter. It must of course depend upon our degree of knowledge; and, in examining the effects of partial knowledge, we must state specifically the case we wish to try. Let us suppose it to be the following. We are in a room which contains an urn. Our knowledge of its contents is limited to this much: that if it contain any thing it is a ball or balls, either black or white, the conditions being interpreted without reference to any thing in the form of expression which may make any one conceivable case more prominent than another. It is clear that a single drawing must either produce nothing, or a white ball, or a black ball. To which supposition do our minds incline? To neither; for there is no circumstance which should turn the scale. If we think for a moment that the possible contingency of ninety-nine black and one white would make a black ball very likely, we instantly remember that the equally possible contingency of ninety-nine white and one black would make a white ball as likely. Caprice, as we should call it, might decide, but this could be only interpreted as the silent whisper of some habit or association of ideas, strong enough to turn a point so nicely balanced, but too weak to be audible by itself; just as the thousandth part of a grain will turn the scales of a chemist, itself being hardly seen and not possible to be felt. But we have supposed ourselves to come into the room without this thousandth part of a grain: we are not asking whether we ever *could* come without it, but what should we do *if* we could. We should not guess in favour of either.

We have required as an axiom the right to consider the impressions produced by different events as comparable in magnitude, and still more, of course, those produced by the different contingencies which the same prospect presents. *Mathematical certainty* (a thing perhaps impossible in the strictest sense) is the terminus or limit towards which our impressions approach as our knowledge becomes greater and greater, and is never attained as long as any doubt whatsoever remains. *Practical certainty* is that high degree of probability on which the mind acts at once, without thinking the counter-probabilities sufficiently large to be taken into account; and it depends upon the character of the individual. A question must be raised as to whether the impression of probability is a fraction of the impression called certainty which varies directly as the numerical amount of circumstances. The mathematician will understand us; but we may put it in this way.

1. To take one extreme case: suppose the life of an individual depending upon his guessing the result of one drawing of the urn already mentioned; suppose a second power overruled the first, and allowed him to name two cases, granting his life if the result fell within either; suppose a third power, making one more interference, and allowing him to name three cases; which would render certain the safety contingent in the first two cases: for he would of course name as his three allowed cases, *none*, *white*, and *black*, one of which it must be. Now the impression of obligation and of benefit received being proportional, would he feel more obliged to the second or the third? We suppose it would be answered without hesitation to the third; that is, these apparently equal steps to certainty would seem to add very unequal benefits, or very unequal senses of the probability of escape. Those who have considered this subject (and appeal to experience is necessary) have never doubted this phenomenon of the human mind; and under the name of *moral probability* have distinguished that impression which has direct reference to the particular effect of the event upon the individual. Thus they have considered that two men who play for equal stakes with very unequal fortunes are not, in fact, (though staking the same sums of money,) playing equally, and ought not to regard the result with impressions of the same force.

2. Now let every thing remain the same as before, except that the risk incurred is nothing at all, or of too small consequence to upset the mind by hope or fear. The question now is, would the second or the third power be held to have conferred the greater benefit? We are afraid that in this case the third would be charged with having *spoiled the fun*. But supposing it a matter of common life, and all stimulus of gambling out of the question, it seems to be the general opinion of mankind that the second and third powers would have acted equally: this is proved by the uniform consent of those who have written on the subject, and the almost uniform reception of their opinions. To some sort of consent of mankind every theory on this subject would be absurd if it did not appeal. What would be a theory of *probabilities* (that is, of the manner in which certain impressions of the human mind are to be compared) which did not appeal to the voice of the majority? The question at issue is, Does the preceding statement fairly represent that voice? Or it might even be put in this way: Would opinions on one side and the other be such as to make the preceding notions a fair average statement? For even in that case it would be the best probable rule of action.

(8.) We now lay down the following definitions.

1. *Moral probability* is the impression existing with regard to the happening of an event depending upon the constitution of the individual, his knowledge of the circumstances, and the effect the event will produce.

2. *Mathematical probability* is the moral probability in that case, and in that case only, in which the mind is

Theory of
Pro-
babilities.Theory of
Pro-
babilities.

disposed to consider equal successive changes of favourable circumstances into unfavourable, or *vice versa*, as of equal importance; not regarding certainty as possessing any peculiar value, more than would be derived from its being the sum of certain probabilities, and therefore of course larger than either.

3. In future, *probability* means *mathematical probability*, unless the contrary be specified.

4. Absolute certainty *against* an event is denoted by the degree of probability 0 for it; and *vice versa*. Absolute certainty for an event is denoted by the degree of probability 1; and all intermediate degrees of probability are denoted by fractions, as follows.

5. The probability *in favour* of an event is such a proportion of 1 as the number of *favourable* cases is of the whole: all the cases being considered as equally probable. Thus the probability of drawing a white ball where 3 out of 10 are white is $\frac{3}{10}$.

6. The probability *against* an event is such a proportion of 1 as the number of *unfavourable* cases is of the whole. Thus the probability against drawing a white ball in the preceding case is $\frac{7}{10}$.

7. *Chance* is used synonymously with probability, but mostly in reference to problems of few cases, in which the expectation, that results will nearly agree with a general average, is not great.

8. When the number of favourable exceeds that of unfavourable cases, the *odds* (inequality of probabilities) are said to be in favour of the event, and *vice versa*. In the preceding instance the *odds* are against drawing a white ball, as 7 to 3, or $2\frac{1}{3}$ to 1.

9. The sum of all the different probabilities which any case presents must be 1: and if any different subordinate cases be collected, and the happening of either one or other of them be the condition under which an event is to be considered as having happened, the probability of that event is the sum of the probabilities of the several events of which it is disjunctively composed. Thus if there be 3 red, 2 white, and 9 black balls, the event "one of the two red or white" has a probability $\frac{3}{14} + \frac{2}{14}$ or $\frac{5}{14}$. For the event may evidently happen in five ways out of 14.

(9.) We shall now proceed to some applications.

Lemma 1. The number of ways in which n counters can be taken out of p counters, supposing each to be put back again before the next drawing, is p^n . Let this be true for any one value of n , say 5; then there are p^5 ways of drawing 5, but every one of these ways has p different ways of being converted into a drawing of six: therefore $p^5 \times p$ or p^6 is the number of ways of drawing six. That is, if this theorem be true for any one value of n , it is true for $n + 1$: but it is true for one drawing, (there being p or p^1 ways of drawing,) therefore it is true for all.

Corollary. This case remains exactly the same, if instead of p distinct counters $C_1 C_2 \dots C_p$, we suppose there to be n_1 like C_1 , n_2 like C_2 , &c., there being p different *sorts* in all, and two of a sort being considered as the same event.

Thus the number of different events arising out of four throws with a halfpenny is 2^4 or 16, as follows (H stands for head, and T for tail):

H H H H	T H H H	T H T H	T T H T
H H H T	H H T T	T T H H	T H T T
H H T H	H T H T	H T T H	H T T T
H T H H	T H H T	T T T H	T T T T

The following questions will enable the reader to see whether he understands the definitions.

Which is the most probable event, considering the same number of H and T as the same event, whatever be the order? *Answer.* H twice, and T twice, which call $(H_2 T_2)$, of which the probability is $\frac{6}{16}$, while that of $(H_1 T_3)$ and of $(H_3 T_1)$ is only $\frac{4}{16}$. That of (H_4) is $\frac{1}{16}$, and also of (T_4) .

What is the probability of H once at least? *Ans.* $\frac{15}{16}$.

What are the odds in favour of H once at least? *Ans.* 15 to 1.

What are the odds against alternate throws? *Ans.* 7 to 1.

Let it be observed that p^n is the coefficient of x^n in the developement of $\frac{1}{1 - px}$.

(10.) *Lemma 2.* If the whole number n be made up of $n_1 n_2 \dots n_p$, then the number of ways in which n drawings of p counters give n_1 of C_1 , n_2 of C_2 , &c., without reference to order, is

$$\frac{1 \cdot 2 \cdot 3 \dots n-1 \cdot n}{1 \cdot 2 \cdot 3 \dots n_1 \cdot 1 \cdot 2 \cdot 3 \dots n_2 \dots 1 \cdot 2 \cdot 3 \dots n_p} \text{ or } \frac{[n]}{[n_1][n_2] \dots [n_p]}$$

This follows from the common theory of permutations. The new definition is

$$[n] \text{ means } 1 \cdot 2 \cdot 3 \cdot 4 \dots n-1 \cdot n \quad (\Gamma(n+1) \text{ of Legendre}).$$

The preceding formula is the coefficient of $a_1^{n_1} a_2^{n_2} \dots a_p^{n_p}$ in the development of
 $(a_1 + a_2 + \dots + a_p)^n$.

Theory of
Pro-
babilities.

Theory of
Pro-
babilities.

Lemma 3. The number of combinations of n quantities which can be taken out of p quantities is (as is well known)

$$\frac{p \cdot p-1 \dots p-n+1}{1 \cdot 2 \dots n} \text{ or } \frac{[p]}{[n][p-n]},$$

and the number of permutations is $p \cdot p-1 \dots p-n+1$ or $\frac{[p]}{[p-n]}$.

(11.) There is in algebraical multiplication a resemblance to the sorting of all the events which can happen by combination of simple events, which is one of the most important principles in the application of mathematics to this subject. If the first of three urns give out either a or b , the second either c or d , the third either e or f , it is plain that the results of a drawing give one of the following:

$$a c e, a c f, a d e, a d f, b c e, b c f, b d e, b d f.$$

Now consider $a, b, &c.$ as algebraical quantities, and the sum of the preceding terms (juxtaposition denoting multiplication) is no other than the product

$$(a + b)(c + d)(e + f).$$

Write these two under one another.

$$(a + b)(c + d) = ac + ad + bc + bd$$

$$(a \text{ or } b)(c \text{ or } d) \text{ is either } ac \text{ or } ad \text{ or } bc \text{ or } bd.$$

The first is a well-known algebraical truth; the second is a truth also, if by $(a \text{ or } b)$ we mean an event which may be one or the other, and by $(a \text{ or } b)(c \text{ or } d)$ the consecutive fulfilment of two such contingencies. It is palpable that $(a \text{ or } b)$ followed by $(c \text{ or } d)$ must be either ac or ad , or bc or bd . The analogy which exists between the two preceding processes directs us to the following theorem. Let $+$ be read *or*; let $(\cdot)$, $(\cdot)$, $(\cdot) \dots$ denote a succession of events, each having the contingencies described in the brackets, so that $a + 2b + 3c$ means that we draw in a lottery* having the following tickets,

$$a \quad b \quad b \quad c \quad c \quad c,$$

and is read; a , or b in either of two ways, or c in either of three ways. This being premised, the results of the process, which under algebraical definitions would be multiplication, are true.

$$\text{Thus from } (a + 2b + 3c)^2 = a^2 + 4ab + 4b^2 + 6ac + 12bc + 9c^2$$

we gather that by a drawing from each of two urns which contain

$$a \quad b \quad b \quad c \quad c \quad c$$

we have one chance in favour of aa , four for ab , four for bb , six for ac , twelve for bc , and nine for cc ; as would be evident by developing

$$(a + b + b + c + c + c)(a + b + b + c + c + c)$$

by multiplication. The whole number of events is the sum of all the coefficients, or

$$1 + 4 + 4 + 6 + 12 + 9, \text{ or } 36;$$

this is what the preceding expression becomes when a, b , and c are severally $= 1$.

(12.) We shall now proceed to lay down some primary theorems in the manner in which Laplace has given them, but not in the order.

Principle I. Is the definition of probability already given, in the case where all events are equally possible. Let f and u be the number of favourable and unfavourable cases, and the probabilities are

$$\text{for it } \frac{f}{f+u}, \text{ against it } \frac{u}{f+u}.$$

(13.) **Principle II.** The probability of the happening of two, three, or more events, is the product of the probabilities of their happening separately. This depends upon the following; that if there be f and f' cases in favour of two events, the number of ways in which they may happen together is ff' . For any one of the f ways in which the first may happen may be combined with any one of the f' ways in which the second may happen. The whole number of possible cases is, by the same rule, $(f+u)(f'+u')$, which gives for the probability of happening

$$\frac{ff'}{(f+u)(f'+u')} \text{ or } \frac{f}{f+u} \times \frac{f'}{f'+u'}$$

the product of the simple probabilities. It is the test of correctness in many problems, that the development of the denominator furnishes numerators for the probabilities of all the possible cases. In the preceding instance,

* This is merely saying we take a hazard of any sort. All affairs of life are more or less lotteries. One merchant, for instance, has such skill that his success in business may be likened to drawing for the chance of a white ball where one of ten only is black. The ignorance of another reverses the case. The continual occurrence of illustrations by lotteries, and such contingencies, leads many to suppose that this subject is only applicable to games of chance. To any one who depends so much upon words we may present the following application of them, which is perfectly consistent with our definitions. "Certainty is the chance of drawing a white ball from a lottery of ten balls, all white."

Theory of
Pro-
babilities.

or the whole number of compound events consists of

$$(f + u)(f' + u') = ff' + fu' + f'u + uu',$$

ff' ways in which both may happen.
 fu' ways in which the second *only* may fail.
 $f'u$ ways in which the first *only* may fail.
 uu' ways in which *both* may fail.

Theory of
Pro-
babilities.

For instance, suppose the following syllogism: A is B; B is C; therefore A is C. Suppose the first assertion is considered as having ten to one in its favour, and the second three to one. Now the probability of the conclusion is entirely that of both premises being true, from which it necessarily follows. The probabilities for the single premises are $\frac{10}{11}$ and $\frac{3}{4}$, the product of which $\frac{15}{22}$ is that of the conclusion, or 15 to 7, little more

than two to one. This, it must be observed, is independent of any force the conclusion may derive from other sources, a case we shall presently consider. In this way it is obvious that a lengthened chain of arguments, unless each be a certainty, produces an inference, the probability of which weakens at every step. But at the same time it is difficult, if not impossible, to produce a chain of arguments of which the reasoner can rest the result on those arguments only. The result will of itself, without reference to its supports, produce an impression of its own, which strengthens the premises if it be favourable, and weakens them if unfavourable. Thus the propositions of geometry as they severally appear, have an evidence of their own, were it not for which, we feel quite confident that in the mind of a beginner unused to reasoning they would, after the first few propositions, rest on authority only.

(14.) *Principle IV.* If the different ways in which an event may happen are not equally probable, the probability is the sum of the probabilities of the different cases; *but it must be remembered that each method of happening must be considered as contingent upon that method being the one which actually arrives.* For instance, suppose two closed urns as follows.

(3 wh. 4 bl.) P (4 wh. 3 bl.) Q.

A white ball may be drawn in two ways, from P or from Q. Suppose the drawer has no preference in his mind for either. The common mistake would be to say that the probability of the white ball from the first is $\frac{3}{7}$, from the second $\frac{4}{7}$, and therefore from both $\frac{3}{7} + \frac{4}{7}$ or 1, that is, certainty. This result is absurd; but the reason of the mistake is that his going to one urn or another is itself a contingency. As to the urn P we should ask, 1. What is his chance of selecting that urn? This is $\frac{1}{2}$. 2. Having selected that urn, what is his chance of drawing a white ball from it? This is $\frac{3}{7}$. Consequently his chance of going to that urn, and selecting a white ball is $\frac{1}{2} \times \frac{3}{7}$, and for the other $\frac{1}{2} \times \frac{4}{7}$. The sum of these two is $\frac{1}{2}$, or the two together give an even chance. This is easily verified; for any given ball in one urn being as likely of its kind to come up as any other, we do not alter the problem by pouring the contents of one urn into the other, and thus we have

(7 wh. 7 bl.).

If the drawer have any bias on his mind which renders it two to one that he will choose P in preference to Q, a by-stander must calculate thus: the chance of P is $\frac{2}{3}$, that of a white ball from it $\frac{3}{7}$; therefore $\frac{2}{3} \times \frac{3}{7}$ or $\frac{6}{21}$ is the probability thus derived, and $\frac{1}{3} \times \frac{4}{7}$ or $\frac{4}{21}$ that of a white ball from Q, and $\frac{10}{21}$ is the total probability. We may suppose no such bias to exist, and place the cause of a similar alteration of probabilities in the circumstances themselves, by having three urns,

(3 wh. 4 bl.) P (3 wh. 4 bl.) P (4 wh. 3 bl.) Q,

the total probability for a white ball (no bias existing) is

$$\frac{1}{3} \frac{3}{7} + \frac{1}{3} \frac{3}{7} + \frac{1}{3} \frac{4}{7}, \text{ or } \frac{10}{21} \text{ as before.}$$

We may thus illustrate the dependence of the probability upon the knowledge of the spectator. We have supposed that he knows the contents of the urns, but not which is the one and which is the other. If he know nothing of the contents, the chance is even for a white ball from each, and the total probability is $\frac{1}{2} \frac{1}{2} + \frac{1}{2} \frac{1}{2}$ or $\frac{1}{2}$, an even chance, as of course it should be.

Again, the problem undergoes a change during the process to a by-stander who knows which urn has the four white balls. The probability to him varies with the motions of the drawer's hand, according as he sees reason to

Theory of
Pro-
babilities.

suppose he is more likely to take one or the other. At the beginning both parties have the probability $\frac{10}{21}$; but the moment the drawer has inserted his hand into P, the probability in the mind of the spectator is $\frac{3}{7}$ or $\frac{9}{21}$.

Theory of
Pro-
babilities.

(15.) Let us now consider the following case. It is an even chance that A is B, and the same that B is C; and therefore 1 to 3 from these grounds only, that A is C. But other considerations of themselves give an even chance that A is C. What is the resulting degree of evidence that A is C? Let us take all the possible cases.

From the premises { 1. An even chance that A is B } { 3. An even chance that A is C
 { 2. An even chance that B is C } { from other evidence.

Let (1) denote the truth of 1, and [1] its falsehood. The following are possible cases:

- | | | | |
|----------------|----------------|----------------|-----------------|
| 1. (1) (2) (3) | 2. (1) (2) [3] | 3. [1] (2) (3) | 4. [1] (2) [3] |
| 5. [1] [2] (3) | 6. [1] [2] [3] | 7. (1) [2] (3) | 8. (1) [2] [3]. |

Here are eight cases, equally probable, each consisting of a result compounded of three results, and therefore having a probability of $\frac{1}{8}$. Of these, cases 1, 2, 3, 5, and 7 make the conclusion "A is C" necessary, either by the establishment of the argument, or of the independent evidence. That is, five out of eight equally possible combinations are in favour of A being C, or the odds for it are 5 to 3.

Let us now treat the preceding question as having two contingencies, the compound argument (1 to 3 for), and the independent evidence (an even chance). We have, therefore, four possible cases.

	Probability of "A is C."
Argument and evidence both true	$\frac{1}{4} \times \frac{1}{2}$ or $\frac{1}{8}$
Argument false and evidence true	$\frac{3}{4} \times \frac{1}{2}$ or $\frac{3}{8}$
Argument true and evidence false	$\frac{1}{4} \times \frac{1}{2}$ or $\frac{1}{8}$
Argument and evidence both false	0.

The sum of these is $\frac{5}{8}$ as before.

(16.) The above, generalized, is as follows. Let a and $(1 - a)$ be the probabilities for and against the argument, and let e and $1 - e$ be the probabilities from any other source. Then the chance that both are wrong is $(1 - a)(1 - e)$, and of the contradictory, namely, that the result "A is C" follows from one or other is

$$1 - (1 - a)(1 - e) \text{ or } a + e - ae.$$

But this proceeds entirely upon the supposition that an inference can be drawn, and that the arguments which furnish that inference remain with their probabilities unaffected by the circumstances which, on other grounds, give probability or improbability to the result. For in like manner as the certain falsehood of the result proves the falsehood of one or both premises, so the improbability of a result will throw doubt of itself upon the premises, and lower their *à priori* probability. How much of such effect they do produce we cannot ascertain; but it so happens that one indisputable case will show that we can deduce a phenomenon which will, as soon as stated, be recognised and admitted to exist.

The preceding result evidently fails to represent the character of usual impressions by probable reasoning. Let there be $\frac{3}{4}$ of probability for "A is C" from argument, but suppose other grounds of evidence give only $\frac{1}{1000}$ of probability for it, or 999 to 1 against it. Can it be believed that the latter adds probability to the former, or that the total probability is

$$\frac{3}{4} + \frac{1}{1000} \left(1 - \frac{3}{4}\right), \text{ which is greater than } \frac{3}{4}?$$

This result is admissible, provided the methods by which $\frac{3}{4}$ is established have a probability which is not shaken by the smallness of the probability for the result independently of them. But this can hardly be the case, and the preceding theorem therefore omits a necessary consideration which applies with more or less force whenever e is less than a .

But there is one case in which the preceding objection does not apply. When the independent probability e is one half, the evidence for the premises cannot be affected by it. When a result of argument cannot be considered as either likely or unlikely, we do not go back to the premises with any consideration drawn from the

Theory of
Pro-
babilities.Theory of
Pro-
babilities.

nature of the result. Let $e = \frac{1}{2}$, which gives $a + e - ae = \frac{1}{2} + \frac{1}{2}a$. This is, we think, the proper representation of the force of an argument, of which a is the compound probability of the premises, and of which the result is to be considered as neither likely nor unlikely in itself, nor having any force but what it derives from the premises. The following theorem will be readily admitted on its own evidence.

If any assertion appear neither likely nor unlikely in itself, then any logical argument in favour of it, however weak the premises, makes it in some degree more likely than not.

In the manner in which writers on logic apply the calculus of probabilities, this result never is a consequence of their suppositions. For what we have called a is their resulting probability of the argument. Suppose, for instance, a writer on logic presumed that the argument from analogy gave $\frac{3}{10}$ to the probability that there is vegetation in the planets, which must be considered as a thing neither likely nor unlikely in regard of evidence derived from any other source. He would assert $\frac{3}{10}$ to be the probability of this result, that is, *less after an argument in favour of it than it was before*. We substitute $\frac{1}{2} + \frac{1}{2} \cdot \frac{3}{10}$ or $\frac{13}{20}$.

(17.) The chance of throwing at least one head in two throws is $\frac{3}{4}$. Let us suppose that the thrower is to leave off as soon as he throws once. There are then three cases. 1. H the first time, in which case he leaves off. 2. T the first time, and H the second. 3. T the first time, and T the second. These are the only three events contemplated; two are favourable, and one unfavourable: the probability of H then appears* to be $\frac{2}{3}$. But it has been forgotten that the three cases are not *equally probable*. For H the first time we have $\frac{1}{2}$, for $T_1 H_2$ we have $\frac{1}{2} \times \frac{1}{2}$ or $\frac{1}{4}$, and for $T_1 T_2$ we have also $\frac{1}{4}$. Consequently the probability of H once in two throws is $\frac{1}{2} + \frac{1}{4}$ or $\frac{3}{4}$, as before.

But at the same time, with regard to the objection of D'Alembert cited in the note, we must observe that if any individual really feel himself certain, in spite of authority and principle, as here laid down, that the preceding cases are equally probable, he is fully justified in adopting $\frac{2}{3}$ instead of $\frac{3}{4}$, till he see reason to the contrary, which it is hundreds to one he would find, if he continued playing for a stake throughout a whole morning, that is, accepting bets of two to one that H would not come up once in two throws, instead of requiring three to one. He must begin to reason mathematically from that point at which he is convinced he has the means of applying mathematical principles; and remark that the accordance of apparently different methods does not confirm the theory, but the correctness with which the theory has been applied. The individual just supposed, has applied correct mathematics to a manner in which he feels obliged to view the subject, in which we think him wrong, but the error is in the first of the two considerations in (6.), and not in the second.

(18.) All that we have hitherto done is to lay down *direct* principles, in which we reason from known causes to probable events. We now come to *inverse* principles, in which we reason from known events to probable causes.

Principle IV. Knowing the probability of a compound event, and that of one of its components, we find the probability of the other by dividing the first by the second. This is a mathematical result of the last too obvious to require further proof.

(19.) *Principle V.* When an event has happened, and may have happened in two or three different ways, that way which is most likely to bring about the event is most likely to have been the cause. This is so well known a principle that it is continually in our mouths. "A man has died; is it A, B, or C?"—"Most likely it is A, because he was in weakest health, and therefore most likely to die." This is so common a phraseology that we at first imagine we are using tautology. But on considering a moment we see that it is not so. Death has happened, either to A, B, or C; an event is given, and we ask in which out of given ways it arose. We immediately, not change the phrase, but reverse the supposition, and make the event a contingency. If death be to happen, to which is it most likely to happen?—To A, it is presumed. Then, we say and know that the death which has happened is most likely that of A.

This principle is not in reality different from the one first stated (Principle I.) If the causes of an event be all equally likely, we can give no preference to one over another, and consequently, if they be n in number, each has a probability $\frac{1}{n}$. But to say that one cause is more probable than another is merely to say it is a greater collection of *partial causes* than are contained in the other. Now what are we considering? An event has happened, say a white ball has been drawn, and it must be from one of the two,

* So said D'Alembert, "Dès que croix sera arrivé au premier coup, on n'en jouera pas un second; et ainsi les deux premiers combinaisons croix croix, croix pile, se réduisent à croix seul."—*Opuscules*, vol. ii. p. 16.

Theory of
Pro-
babilities.

7 wh. 3 bl., or 10 wh. 2 bl.

Theory of
Pro-
babilities.

A white ball has been drawn; let us, without altering the contingencies of either, change the number of balls in both, so that the number of balls shall be the same in both. Multiplying both numbers in each urn by the same number does not alter the probabilities resulting from either, and therefore does not change the character of either as a cause. We thus have

84 wh. 36 bl., or 100 wh. 20 bl.

There are now 120 balls in both; and the only question is, was the white ball actually drawn one of 84, or one of 100? Each ball has the same chance of being drawn, whichever it be in, namely $\frac{1}{120}$. Because the ball is not black, we may strike out the black balls altogether, and if we suppose the white balls supplied from a third urn which contained 184, the chance of the ball which was drawn having been in the first urn is $\frac{84}{184}$, and in the second $\frac{100}{184}$. These are then the chances of the observed event having arisen from the two causes respectively. But

$$\frac{84}{84 + 100} = \frac{\frac{84}{120}}{\frac{84}{120} + \frac{100}{120}} = \frac{\frac{7}{10}}{\frac{7}{10} + \frac{10}{12}}, \quad \frac{100}{184} = \frac{\frac{10}{12}}{\frac{7}{10} + \frac{10}{12}}$$

But $\frac{7}{10}$ and $\frac{10}{12}$ are the probabilities of a white ball appearing, when the causes are chosen, and the appearance of a white ball is the contingency. And we may thus put the principle in a mathematical form as follows. If an observed event may arise from either of the causes A, B, C, &c., and the probabilities of its happening on the assumption of the several causes be $a, b, c, \&c.$; then the probability of the cause A having been the one which really did act, is

$$\frac{a}{a + b + c + \&c.}; \text{ that of B is } \frac{b}{a + b + c + \&c.} \&c.$$

Suppose a ball to be drawn from an urn of which all we know is that it contains three balls. It is white, and is restored after drawing. The second and third drawings give a white ball also; what is the probability that all in the urn are white, &c.?

Possible causes.	Assuming this cause, the prob. of the observed event is
1 white, 2 black	$\frac{1}{27}$
2 white, 1 black	$\frac{8}{27}$
3 white, 0 black	1 or $\frac{27}{27}$
Then for 1 white, 2 black, the prob. is	$\frac{1}{1 + 8 + 27}$ or $\frac{1}{36}$
2 white, 1 black.....	$\frac{8}{1 + 8 + 27}$ or $\frac{8}{36}$
3 white, 0 black.....	$\frac{27}{1 + 8 + 27}$ or $\frac{27}{36}$

(20.) *Principle VI.* Having observed an event, and given the degree of probability arising out of it to each possible cause, what is the probability of another event happening in a given manner? This problem requires the application of Principle III. Calculate the probability of the prescribed event happening from each cause; that is, multiply the probability of each cause by the probability of the indicated event following it, and add the results together.

Thus the probability that the fourth drawing will give a white ball, in the last example, is found as follows.

Prob. of the circumstances being as below.	Prob. which these circum- stances give the event.	Prob. of the event really happen- ing from these circumstances.
1 white, 2 black $\frac{1}{36}$	$\frac{1}{3}$	$\frac{1}{3 \cdot 36}$ or $\frac{1}{108}$
2 white, 1 black $\frac{8}{36}$	$\frac{2}{3}$	$\frac{8 \cdot 2}{3 \cdot 36}$ or $\frac{16}{108}$
3 white, 0 black $\frac{27}{36}$	1 or $\frac{3}{3}$	$\frac{3 \cdot 27}{3 \cdot 36}$ or $\frac{81}{108}$
Total probability required,		Sum $\frac{98}{108}$

Theory of
Pro-
babilities.

If a' , b' , &c. be the probabilities which the several causes would give the prescribed event, and a , b , &c. those which they would give to the observed event, the probability of the prescribed event is, by this principle and the last,

Theory of
Pro-
babilities.

$$\frac{a a' + b b' + \&c.}{a + b + \&c.}$$

(21.) With regard to the preceding principles, it is clear that we may determine by them the most probable cause; out of which immediately arise two distinct branches of the subject.

1. When we propose to abide by the *absolute* event of a chance in such manner that any deviation from a prescribed method of happening shall be a total loss, we are *gambling*. Thus in throwing up a hundred half-pence, the most probable of all events is that there shall come down fifty heads and fifty tails; that is, this single combination is more probable than any other which can be named. But it is not therefore probable in itself; for if we consider all the other cases put together, their united probabilities far exceed the probability of that which, compared with other single events, is the most probable. Thus though a horse may be named which is likely to beat *any one* of the other horses in a race, it is not therefore likely that he will beat them all. Suppose a horse had been tried against nine other horses, and had been found to beat each of them five times out of six. If then we call x the probability that any one of the nine will win, it is clear that $5x$ is the probability for the favourite. But the sum of all the probabilities against the latter is $9x$; and though $5x : x$ is in favour of the first named, against any one competitor, yet it is $5x : 9x$ against him on the whole field. The neglect of this consideration in common life leads to no good results. It is the argument on which speculators, trusting to their skill in single instances, imagine it to be as likely that they shall succeed in all their undertakings, as in any one. The only way to act prudently is by decreasing the risk as the number of speculations increases. If this be done, the greater the number of speculations, properly understood, the safer is the result.

(22.) 2. This brings us to the second species of risks, in which, instead of putting all upon one event, the risk is divided among a great number. And this is the principle of prudence whether the risk of each individual event be small or great; indeed when the number of events is very great, it is indifferent (as to safety) whether the risk of each be small or great. Suppose that in the preceding case the speculator is to pay a hundred pounds if any event come up except 50 heads and 50 tails. He is gambling, even though he be to receive a sum in case of that event, large in proportion to its improbability. But if he divide his risk in this way: if he engage to pay a pound for every head, and receive one for every tail, the gambling character of the transaction is materially diminished. The odds are now against his being really a staker of ten pounds; and if he were allowed to make as many throws as he pleases, and were to receive, say a shilling certain for every throw, independently of his hazard, he might go on until he had gained any sum.

The mathematical part of the first species of risks is comparatively easy: that of the second very difficult. Hence books on this subject are generally on gambling, and in all, questions of the first sort precede those of the second. And from this arises in great measure the character which this science bears among those who are unacquainted with the higher branches of mathematics.

(23.) We shall first address ourselves to some superstitions which we have observed that ignorance on this subject allows to exist even among educated men in this day.

1. We have heard it gravely asserted by sensible men, that there is no doubt whatever of *runs of luck*, in a tone which implied that they think it is something extraordinary.* We, on the other hand, should be as much surprised if there were not runs of luck, as they are at what really takes place, which we think to be the probable order of events. On inquiring what is meant by a run of luck, we find it is the occurrence, skill being equal between two players, of a succession of events on one side. Thus the smallest run possible is that A should win two games following of B, and hardly merits the name: three games following is a run, and four very decidedly so. Let us then call three games or upwards following each other with the same result a *run of luck*. Let A and B sit down to play four games with equal skill. There are sixteen possible cases, of which six, namely, (A denotes that A wins, &c.) A A A A, B B B B, A A A B, B A A A, B B B A, A B B B, contain a run of luck. It is therefore only 10 to 6, or $1\frac{2}{3}$ to 1, that there is no such thing in any four games. If they play five games, there is an even chance for a run of three; and if they play six games, there are 38 out of 64, or 38 to 26 in favour of a run of three; that is, out of six games it is *more likely than not* that there should be a run of three. We put down the total number of possible events which six games may give; that is, we write down 32 cases, and the other 32 may be found by changing B into A and A into B.

A A A A A A	A A A B B A	A A B A A B	A B B B A A
A A A A A B	A A B B A A	A B A A B A	A A B A B B
A A A A B A	A B B A A A	B A A B A A	A B A B B A
A A A B A A	B B A A A A	A B A A A B	A B A A B B
A A B A A A	A A A B A B	B A A A B A	A B A B A B
A B A A A A	A A B A B A	B A A A A B	A B B A A B
B A A A A A	A B A B A A	A A A B B B	A A B B A B
A A A A B B	B A B A A A	A A B B B A	A B B A B A

Here 19 out of 32 exhibit runs of three or more, and when the whole process is doubled, there will be 38 out of 64, as before stated.

* We are sure that many people have a lurking belief in some mysterious sympathies or antipathies existing between the cards or dice and themselves.

Theory of
Pro-
babilities.

In this way, by taking a sufficient number of games, a run of four becomes probable, or of any number however great. It would be possible to play a number of games so great that it should be a hundred to one in favour of the series containing a run of a hundred games.

Theory of
Pro-
babilities.

When the game is partly skill and partly chance, the probabilities of a run are increased. The party who wins the first game gets confidence, and ease of mind, while the reverse takes place with the other. The first is therefore rendered more skilful than the second, or which is the same thing, placed in circumstances which favour the undisturbed application of his skill.

This belief in runs of luck is exactly the feeling of destiny which has predominated in the minds of many historical characters, and particular of the Emperor Napoleon. Granting somewhat to temperament, the greater part of the feeling appears to us to have arisen from an idea that the common order of events is regular succession of good and bad fortune, and that any thing else is to be attributed to some particular cause, to which the first cannot be traced. Let those who are inclined to believe that *runs of luck* are out of the common order of events watch the succession of carts and carriages in a crowded street. It will be found that a crossing will sometimes be clear for a minute or two; then a rush, more or less, of vehicles will approach, and the events of successive minutes will exhibit every variety of succession, from the average number up to five or six times as much, or down to nothing. A continual average would render the great thoroughfares in London impassable.

(24.) 2. We have frequently heard it asserted that a change of circumstances, such as taking another chair, or the like, *changes the luck*. If the preceding cases be observed, and if we suppose this alteration of circumstances to take place at the end of the first three games, it will be found that in 22 out of 32 cases the luck is not the same both before and after, and that in 16 out of 32 the first and last triads present decided differences. It is then an even chance at least that a change of position will happen immediately before a triad which will differ in its character from that immediately preceding; and it is always 11 to 5 at least against the approaching triad resembling the preceding one, in the number of games won and lost. But if A having *lost* three games in succession should change his chair to get rid of his ill luck, (which we have seen done,) he then may easily suspect some virtue peculiar to his new position, for it is 7 to 1 that there must be some alteration, and any alteration is in his favour. Those, therefore, who adopt this method of courting fortune, should try it on all sorts of luck; for by using it only when she is very much against them, they put the majority of possible cases on their sides as well as the magic of the new seat.

(25.) 3. A confusion very often exists in the mind between the joint probability of two events which are to happen, and the same where one *has* happened. Thus say, it is beforehand unlikely that a man should receive two letters by the post; suppose that it is an even chance he receives one, and that he has ten correspondents. Consequently, supposing the probabilities of their severally writing on any one day to be the same, the chance of

either writing on a given day is $\frac{1}{20}$. Now he knows that his correspondent A must write on a particular day: he therefore thinks it unlikely that either of the others will write on that day, for he calls it unlikely that he should receive two letters on one day. He here compares his position with that of ordinary days, in which he is certain

of no letter whatever: in which case, since there are $\frac{1}{2} 10 \cdot 9$, or 45 pairs of correspondents, either of whom may write, and since the probability of any one pair both writing is $\frac{1}{20} \times \frac{1}{20}$, the probability of his receiving two

letters *only* is $\frac{45}{400}$, and so on. But when one letter is certain from A, the probability of his receiving two letters only is exactly the probability of his receiving the second letter, which, from all the remaining nine correspondents, is $\frac{9}{20}$. Similarly, a man may say, "It is very improbable that I should be robbed twice in one day; I

have been robbed once, and therefore most likely shall not be robbed again." Here is the same fallacy; it is very unlikely that two robberies *should* take place in the same day; but when the first *has* taken place, the probability of *two* becomes the same as the probability of the remaining one.

(26.) We now proceed to the principles on which pecuniary risks are proportioned to the probabilities of the events on which they depend. First, let us suppose that the sum in question is of trifling consequence, so that it is indifferent to the speculator what the result may be. Suppose that the chances are 2 to 1 against his receiving a pound. It is clear that his chance has a value to him; he may not gain, but he is in a different situation from a person who has no risk upon the same event. We may consider the subject in two different ways.

1. As a matter of gambling. Let us suppose the pound must be given either to A (the speculator in question) or to B or C, and that all three have the same chance. It is then 2 to 1 against A, as proposed. If they all three agree to relinquish the hazard, it is clear that the pound must belong equally to all three, or if divided, must be equally divided; for no reason can be given why A should receive any sum, which is not equally applicable in favour of B or C. Hence each would receive one-third of a pound, and if the stake were to be made up by equal contributions, each must give one-third of a pound, and take his chance of receiving all or nothing. If C sell his expectation to B, then B has two chances where A has one and consequently must, if they draw stakes, receive two-thirds of the pound. Hence

Principle VII. The advantage of a contingent benefit, or the expectation which the speculator should have, must be such a proportion of the benefit, as his probability of getting it is of unity.

(27.) 2. As a matter of commercial speculation. In this case a great many such contingencies are contemplated, and the merchant is to calculate in what manner he shall probably make the gains cover the losses,

Theory of
Pro-
babilities.

and realize a profit on the money invested at the same time. Let us suppose there are a ways of gaining, and b ways of losing, and that there is a number n of speculations in question, depending on n events of the same sort. In the development of

Theory of
Pro-
babilities.

$$(a+b)^n \text{ or in } a^n + n a^{n-1} b + n \frac{n-1}{2} a^{n-2} b^2 + \dots$$

we see (11.) in the coefficients the number of ways in which all, all but one, &c., may succeed, and if we divide both sides by the whole possible number of cases $(a+b)^n$, and let

$$\frac{a}{a+b} = \alpha, \quad \frac{b}{a+b} = \beta,$$

we have

$$1 = \alpha^n + n \alpha^{n-1} \beta + n \frac{n-1}{2} \alpha^{n-2} \beta^2 + \dots,$$

the terms of which express the probabilities that all, all but one, &c., will succeed. The ratios of these successive terms to those which precede are

$$\frac{n \beta}{\alpha}, \quad \frac{n-1}{2} \frac{\beta}{\alpha}, \quad \frac{n-2}{3} \frac{\beta}{\alpha} \text{ &c.}$$

$$\frac{(p+1)\text{th term}}{p\text{th term}} = \frac{n-p+1}{p} \frac{\beta}{\alpha}; \text{ let this be called } P_p.$$

Let the p th term be the greatest; that is, let P_p be less than unity, and P_{p-1} greater than unity; or $(\beta + \alpha = 1)$

$$\begin{aligned} (n-p+1) \beta &< p \alpha & (n-p-1+1) \beta &> p-1 \alpha \\ (n+1) \beta &< p & (n+1) \beta &> p-1. \end{aligned}$$

But the p th term expresses the probability of losing $p-1$ and gaining $n-p+1$ of the speculations: consequently, in n separate events, against each of which the probability is β , the most probable of all losses is the whole number next below $(n+1) \beta$, which is more likely than any other given loss, though not more likely than any out of the other losses. The preceding relations also give

$$\frac{p-1}{n-p+1} > \frac{n \beta - \alpha}{(n+1) \alpha} < \frac{(n+1) \beta}{n \alpha - \beta},$$

when n is a great number, the two fractions just found are very near to $\frac{\beta}{\alpha}$: whence this theorem.

Of n successive, or simultaneously independent events, the combination which of all others is most likely to happen is that in which the number of losses is to the number of gains most nearly as the probability of losing any one to the probability of gaining it.

We shall afterwards show that though this most likely individual case is not therefore to be expected, yet that the greater the number of speculations in question, the smaller the *per-centage* of deviation which is to be reasonably looked for. This, then, is the primary axiom of commercial prudence, as far as what may be called accidental fluctuations are concerned. If 1000 speculations* be entered into, against each of which it is nine to one, then the undertaker must look to lose 900 and gain 100; he must therefore not adventure, unless upon terms which will make 100 pay the risk of the whole thousand. If each successful speculation would bring £10, he must only invest £1 in each of the 1000. But he must even invest less than this, to compensate the probable departure from the most probable case. There is then a contingency in what are called his *profits*, the remaining part being made up of what he would derive from simply investing his capital in the funds, and of that portion of profit which he expects for his own labour. Considering that the fluctuations will be on one side and on the other of the most probable case, he may be tolerably certain that his extra *fund for fluctuation* may be made a source of profit; but it must always exist, especially at the commencement.

(28.) The preceding views, though not *numerically* acted upon, for want of positive data, are notoriously truths of the commercial world. It is well known that large businesses can exist with lower profits than smaller ones; for the fluctuation fund must be a larger *per-centage* of the whole in the latter case than in the former. The increase of large farms, large manufactories, &c. confirms this abundantly. A large business and a small one, at the same rate of profits, are much like a line-of-battle ship and a boat in a rough sea. Where the first only rocks, the second is upset.

It must not therefore be inferred that a small business is comparatively dangerous. A risk to *some one* there must be, but there are various methods of taking this off the customer. The first is the system of credit, by which all ordinary fluctuations are equalized, and the loss of one month or year is carried to the chances of the next. Where these chances are prudently calculated there is little risk, but where the most probable case has been mistaken, a series of transactions must end by showing a permanent departure from the anticipated series of results. The second is the investment of a fund larger than is necessary for the purposes of business. Thus in the case of an incipient insurance-office, the capital which always appears as a part of the scheme is a reserve for the possible fluctuations of the first years. The largeness of the sum usually staked upon the success of such undertakings is, we suppose, the proof that those who invest it feel perfectly secure, for it is generally much more than can be needed.

* We do not mean the large transactions which *par excellence* have that name, but we consider every transaction, however small, as one case.

Theory of
Pro-
babilities.

The principle above stated being the same as that which applies in a single gambling transaction, it has been customary to consider the two together; but though the results be the same, the difference of the method of deriving them is very great. On a single throw it matters little whether the just expectation be staked or not. But the merchant is certain of ruin sooner or later, if he neglect this principle on the average of his transactions. The first adopts it because there is no reason why he should stake more or less; the second because there are positive reasons why it should be followed, to the exclusion of all other methods. So obvious is the second result to most persons that it might be made the foundation of the authority for the first. When a halfpenny is thrown up many times in succession, it is never disputed that *in the long run*, as the phrase is, there will be as many heads as tails; or if not exactly, very nearly. Consequently, the chances of a single throw are presumed to be equal for both events.

Theory of
Pro-
babilities.

(29.) A systematic gambler, who has many transactions of the same kind, is a merchant whose speculations differ from those commonly called mercantile, only in the individual risks being somewhat greater. But even this is not always the case. To take the instance of a horse-race; suppose one person can find somebody to take any bet he offers, and that four horses, A, B, C, and D, are to start. He offers four bets against each, (he must take care not to bet in favour of any,) namely, a to a' against A, b to b' against B, c to c' against C, and d to d' against D. The following then are his contingencies:

If A win, he gains $b' + c' + d' - a$.

If B win, he gains $a' + c' + d' - b$.

If C win, he gains $a' + b' + d' - c$.

If D win, he gains $a' + b' + d' - d$.

All he has to do then is to make the sum of every three consequents greater than the fourth antecedent. Suppose, for instance, he bets £10 against £10 on every horse; he must then win £20 whichever way the matter may go. Or he may bet 10 to 5 against A, 10 to 6 against B, 10 to 7 against C, and 10 to 8 against D. Then, if A win, he gains £11; if B, £10; if C, £9; if D, £8: that is, £3 worth of fair gambling, and £8 worth of—not always perhaps sheer roguery, but very often so, and generally something very like it. It is evidently a *fool-chase*, not a horse-race, which he is engaged in.

(30.) PROBLEM. To determine the proportions in which the acceptors of the four preceding bets are unfairly dealt with. Suppose the real probabilities of winning are α, β, γ , and δ ; in which case $\alpha + \beta + \gamma + \delta = 1$. The odds for A are α to $1 - \alpha$, or a to $\frac{a\alpha}{1 - \alpha}$; but $\frac{a\alpha}{1 - \alpha} - a' = \frac{(a + a')\alpha - a'}{1 - \alpha}$; if $(a + a')\alpha < a'$, he takes an advantage.

In the case where the betting is fair, the total sum risked upon A's winning is $\frac{b\beta}{1 - \beta} + \frac{c\gamma}{1 - \gamma} + \frac{d\delta}{1 - \delta} - a$.

(31.) The odium which attaches to the character of a gambler, that is, a person who lives upon mutual transactions which necessarily involve loss to one party or the other, without producing any addition to the commercial prosperity of society, does not arise, or ought not to arise, from his being considered as a spendthrift, or as a man who willingly puts to hazard the means of fulfilling his engagements. If he gamble much and skilfully, not staking too large a proportion of his capital on any one hazard, he is in truth one of the safest merchants going, and cannot be considered as running so great a risk of ruin as is incurred in many honourable and necessary affairs. If he played only with gamblers like himself in knowledge and means, whatever might be thought of the utility of his occupation, nothing could be said against its honesty. But it is evident that a society of such persons must finally come to ruin; for their transactions having no tendency to make any absolute profit, or to increase the value of any thing they handle, the deductions necessary for life must in time destroy their common fund altogether. And herein consists the villainy of their occupation, that any permanent increase of their fund must come from unequal play, that is, from offering or accepting hazards which are unduly in their favour, of course without the inequality being known to and recognised by their opponents. The principle which is carried the length of certain gain in the horse-racing trick we have mentioned must exist more or less throughout their engagements. Now it is clear that no honest man can enter into bargains with A, B, and C separately which would be fraudulent if he had offered all three to A alone, merely because neither of the three knows what has been done by the two others. This matter would be here irrelevant, but for the common notion that this theory has a tendency to promote gambling. On the contrary, it will appear sufficiently from the lower as well as the higher parts of this subject, that there is a proposition which admits of something as like mathematical demonstration as can be possible in any case of morals—namely, that when a man plays for more than he can prudently spend in pleasure with a man or a firm which lives by gambling, there is a fool on one side and a rogue on the other.

(32.) We must refer the reader to the article ANNUITIES for the principal applications of the preceding to the commercial cases of annuities, insurances, and life contingencies. Much prolixity might be saved in such works, if it were usual to lay down the general problems as preliminary lemmas, which it is preferred to repeat as often as there are particular cases. These problems we shall now give as simple applications of the preceding principles. Let the existence of any set of circumstances be called a *status*, which may be either actual, or prospectively certain, or prospectively contingent. A benefit may accrue to an individual yearly during the continuance of an actual *status* which must have an end, or it may begin to accrue yearly upon the commencement of a prospective *status* which must come, or of a *contingent status* which may come into existence. And the questions are the following.

1. What must A pay at once to entitle him to receive one pound at the expiration of every 365 days after the completion of the bargain, so long as a given status, existing at the time of the bargain shall continue to exist? This is the problem of annuities.

Theory of
Pro-
babilities.

2. What must A pay down, and continue to pay at intervals of 365 days, so long as a given status continues, to entitle him to receive a pound at the time when he would otherwise have repeated his payment, at the settling day next following the termination of the status? This contains the most common cases of life insurances.

3. What must A pay, and continue to pay as before, so long as two given status both continue, to entitle him to receive a pound, as before, when one of the two status (not either, but one which is named) has terminated?

(33.) To simplify the question, let the first of January be the only day of payment by either party to the bargain, and let it be the birthday of all the parties whose lives are concerned in the status in question. Let P_n be the probability that the status in question in the first problem is in existence at the end of n years from the day of completing the bargain. Let r be the interest of one pound for one year, interest being acquired yearly. Then, in problem 1, the chance which A has of receiving the n th pound is P_n , and its value is therefore $\mathcal{L}P_n$. Consequently, he must now give for that single chance such a sum as, improved at compound interest for n years, will give $\mathcal{L}P_n$, namely, $\mathcal{L}P_n(1+r)^{-n}$, or $\mathcal{L}P_n v^n$, if $v = (1+r)^{-1}$, the present value of one pound to be received at the end of a year. And hence, what he must give for all his prospects is $\sum P_n v^n$, from $n=1$ to such a value that $P_n v^n$ is not worth calculating, or the value of his annuity is $P_1 v + P_2 v^2 + P_3 v^3 + \dots$.

This problem generally admits of no simplification: each term must be calculated separately, or the following method must be adopted. Let us consider the state in which the buyer of the annuity will be after the first year, if the status in question continue, and he should then wish to make another bargain for another annuity. Let $Q_1, Q_2, \&c.$ be the probabilities of the status then continuing one, two, &c. years. Now it is evident that $P_1 \times Q_1 = P_2$, for the event of which P_2 is the chance must arise from the consecutive happening of the events whose chances are P_1 and Q_1 . Similarly, $P_1 \times Q_2 = P_3$ and $P_1 \times Q_n = P_{n+1}$, by which relations it will appear, that if

$$(P) = P_1 v + P_2 v^2 + P_3 v^3 + \&c.$$

$$(Q) = Q_1 v + Q_2 v^2 + Q_3 v^3 + \&c.$$

$$(P) = P_1 v \{1 + (Q)\}.$$

we must have

So that by beginning under such circumstances that the probability of the status continuing more than one year is not worth considering, we may pass to the case of the year preceding, of the year preceding that, and so on, down to the case actually in question. It is thus as easy to form a whole table as to find the present value in the earliest case; and this is usually done, and tables of annuities are thus calculated, to which all the corresponding questions of the second and third problems are referred by formulæ, as we shall proceed to show.

(34.) Let $(P), (P)_1, (P)_2, \&c.$ be the present values of an annuity, namely, (P) at present, $(P)_1$ as it will be a year hence, if the status be in existence, and the bargain be then made, $(P)_2$ the same for two years hence, and so on. We now ask what is the present value of an annuity which is to begin payment n years hence,* if the status be then in existence, and to continue during the remainder of such existence? It is plain that the value of such annuity the instant before the first payment is $1 + (P)_n$; the chance of the status on which payment depends being then existing is P_n , and $P_n \{1 + (P)_n\}$ is what should be paid if money made no interest during the period of deferment; with reference to the interest, the present value of the preceding is $P_n v^n \{1 + (P)_n\}$, an expression of easy calculation by means of tables.

(35.) We shall now consider the second problem, which is that of the present value of an insurance. The bargain made by A is made up of a series of separate bargains; he is to receive at the end of the n th year one pound, if the status determine in the n th year. Now that it will determine in the n th year, and in no other, is the fraction by which the probability of its failing in n years exceeds that of failing in $n-1$ years, or $(1 - P_n) - (1 - P_{n-1})$. For the probability of the status ending in n years is made up of the probabilities of its failing in the several years of that period. Upon this probability depends the acquisition of $\mathcal{L}1$ at the expiration of n years, and the present value of that prospect is therefore $\mathcal{L}(P_{n-1} - P_n) v^n$. Hence, since $P_0 = 1$, for at the moment of the bargain the status is in existence, the whole present value of a pound to be received at the close of what year soever the status may end in, is

$$(1 - P_1) v + (P_1 - P_2) v^2 + (P_2 - P_3) v^3 + \&c.,$$

or

$$v + v(P) - (P), \text{ or } v - (1 - v)(P);$$

so that the tables of (P) being given, the present values of insurances can be immediately constructed by a simple formula.

(36.) Now to take the next case, namely, what must A pay down, and continue to pay at intervals of a year during the status, to receive $\mathcal{L}1$ at the end of the interval in which it determines? If he paid $\mathcal{L}1$, it is clear that the present value of all his payments (premiums they would be called) is $1 + (P)$; consequently, if he pay $\mathcal{L}x$, the present value of his premiums is $\{1 + (P)\}x$. But this must be equated to the present value of the benefit he is to receive, as determined above, which gives for the premium required

$$\frac{v - (1 - v)(P)}{1 + (P)}, \text{ or } v - \frac{(P)}{1 + (P)}.$$

But if the premiums are to be paid during the continuance of another status, the probabilities of the continued existence of which at the end of the first, second, &c. years, are $P'_1, P'_2, \&c.$, and (P') the present value of the annuity, then the proper premium will obviously be

* It is important to remember that, in treating of annuities, the formulæ are so constructed that they are said to be created a year before payment is made: for instance, that if we buy an annuity January 1, 1836, to date from that day, the first payment is made January 1, 1837. Thus an annuity which begins payment January 1, 1840, is an annuity to commence on that day augmented by one year's purchase.

Theory of
Pro-
babilities.

Theory of
Pro-
babilities.

$$\frac{v - (1 - v)(P)}{1 + (P')}$$

Theory of
Pro-
babilities.

(37.) As an instance of such problems, let us suppose the following question. A father who has a life income allows an annuity to a son and his wife, and intends to allow the same to the survivor, if either of them die before him: he desires to secure that annuity to them jointly, or to the survivor; that is, he wishes to place them in the same position as they would be in if he were certain of surviving both. What should be paid to an office which would engage to fulfil his intentions?

It is plain that the status during which payment of premiums should be made continues as long as, 1. all three are alive; 2. the father and son only are alive; 3. the father and daughter-in-law only are alive; for the object has ceased if the father survive both, and the benefit is to begin if the father die. Let a_n be the probability that the father will survive n years; and p_n and q_n the several probabilities of the son and daughter surviving n years. Then the probability of all three being alive in n years is $a_n p_n q_n$; that of the father and son only surviving is $a_n p_n (1 - q_n)$; and that of the father and daughter only is $a_n (1 - p_n) q_n$. The sum of these, or $a_n p_n + a_n q_n - a_n p_n q_n$, is the probability of premium being payable at the end of n years, and consequently if £1 be paid down, and £1 of premium contemplated, the present value of all premiums is

$$\frac{1 + \sum (a_n p_n + a_n q_n - a_n p_n q_n) v^n}{1 + \sum a_n p_n v^n + \sum a_n q_n v^n - \sum a_n p_n q_n v^n};$$

or

the three latter terms of which can be found from tables, for the second is the value of an annuity to be paid so long as father and son are both alive, the third the same so long as father and daughter are both alive, and the fourth so long as all three are alive. These are technically called annuities on the *joint* lives, and where two lives are concerned, are laid down in tables, which afford a sufficient method of approximating to the case where three are concerned. We will suppose these annuities found, and called (AP), (AQ), and (APQ). That is, if x be the premium necessary, the consideration given for the benefit must be estimated at $x \{1 + (AP) + (AQ) - (APQ)\}$. Now the cases in which the office will be required to pay, at the end of the n th year, are when either of the following status exist: 1. the father dead, and both the others alive; 2. the father dead, and the son only alive; 3. the father dead, and the daughter-in-law only alive; the several probabilities of which are $(1 - a_n) p_n q_n$, $(1 - a_n) p_n (1 - q_n)$, $(1 - a_n) (1 - p_n) q_n$. The probability of one or other of these, which is the status in question, is the sum of the preceding, or $p_n + q_n - a_n p_n - a_n q_n - p_n q_n + a_n p_n q_n$, which, by similar reasoning to the preceding, gives for the present value of such a contingent annuity of £1, $(P) + (Q) - (AP) - (AQ) - (PQ) + (APQ)$; whence, if the office engage to pay £ c annually, the proper premium is

$$x = \frac{(P) + (Q) - (AP) - (AQ) - (PQ) + (APQ)}{1 + (AP) + (AQ) - (APQ)} c.$$

(38.) We shall now come to what is called the *moral expectation*, as distinguished from the mathematical expectation. And here we must take the commercial case first. We have seen that a small and a large business cannot risk the same sums in speculation, unless the former make a higher rate of profit; we shall afterwards see reason to conclude it must be a much higher rate. If we suppose that a business which can always command £10,000 considers it prudent to risk £1000 in a certain speculation, then another which can only command £100 should only risk £10 in the same. To take the extreme case, suppose one man can command pounds, where another can command only pence. What should the second do to preserve his relation unaltered to the first? It is clear that he must, 1. engage in exactly the same transactions; 2. risk one penny where the second risks a pound. In this case both, if either, must be bankrupt together, and both pay the same per-centage of their debts: or if both gain, it is the same per-centage of their invested capital. The only difference between them, mathematically speaking, is in the name of the coin they deal in. Change the word *pound* into *penny*, and the books of the first become those of the second. And the rule of conduct which prudence points out in multifarious transactions becomes, from want of sufficient reason to depart from it on one side more than on the other, the proper guide in single transactions, or in pure gambling. Hence the principle in the next article.

We omit here a circumstance which always is, and must be, in favour of the larger business. The expense of management is one of the risks of the business; now that outlay in a small business cannot be as much less than the same in the large one as the different capitals invested require, according to the preceding rule. It will always take, to manage £10,000, more than half as much as to manage £20,000. We also omit the consideration that a small business not being able to command so large a sum, has not the same range of choice for temporary investments, and must take the best out of a more limited number than the larger one can command. In this country, the increase of proprietary bodies, the funds, &c., so far as they influence the point at all, tend to equalize this disproportion; and the system of credit still more so: but the comparative disadvantage must always exist more or less. On these considerations it is evident that partnerships of small capitals are good to the holders, *cæteris paribus*.

(39.) *Principle VIII.* Two players of different fortunes stake equally when they stake the same proportion of their fortunes, other things being the same: and, all things being the same except the fortunes of two speculators, the sums they ought to risk must be the same proportions of that which they can honestly lose.

This principle will always furnish an answer to those who are pressed by friends of more means than themselves to engage equally with them in any speculation, however probable. If A, who has twice as much as B, take ten shares in a project, and recommend B to do the same, he asks his friend for twice as much confidence in his own judgment as he has himself.

(40.) There is another consideration which enters into the *moral expectation* as it is, and distinguishes it from that which it ought to be; namely, the temperament of the individual, of which we can give no other account

Theory of
Pro-
babilities.Theory of
Pro-
babilities.

than that different persons will look forward in the same circumstances with different degrees of hope. One man will consider himself better off than before when he has bartered one pound certain for an even chance of two: a second will contemplate loss more strongly than gain, and will consider himself damnified by the exchange. The following is a celebrated problem, by which any reader may test himself in this respect.

A penny is thrown up time after time, until a head appears, when the play ends. If it appear the first time, I gain £1; if not till the second, I gain £4; if not till the third £8; and if not till the n th, £ 2^n : what is the value of my expectation?

The probability of there being no head till the n th throw is $\left(\frac{1}{2}\right)^n$; which, multiplied by the benefit £ 2^n gives

£1: consequently, the mathematical expectation for each throw is £1. But there is a mere possibility of head being deferred till any throw whatsoever; whence if the play is to go on *ad infinitum*, the mathematical expectation is $1+1+1+\dots$ *ad inf.*, or infinite. But, nevertheless, no one would give £20 for his chance at this game; unless it were so small a sum that the mere caprice of amusement would be sufficient inducement.

It is plain that different men would stake a different number of throws, according to their different ideas of caution. But the chance of more than a million of millions of millions of pounds at the 60th throw would tempt no one to give a pound for the chance of 59 tails in succession followed by a head. This problem has always led those who have considered it to the conclusion that the actual expectation is not the mathematical expectation; and very justly as far as a single case is concerned. But if any one were to offer us as many sets of sixty throws as we pleased, without long delay or trouble to ourselves, with the addition of only the millionth part of a farthing for each set, over and above what its result would give us, we should propose to have 10^{100} sets of throws, at the cost of £60 each set, and should feel as certain of winning largely as it is possible to be on any subject. And if it be absurd to talk of so many throws, it is not more so than to talk of 10^{18} pounds. A case may appear absurd* when the *presqu'infini* of one of its conditions is prominently insisted upon, to the exclusion of the *presqu'infini* of another. But, nevertheless, with regard to the single case, the following principle must be admitted.

(41.) *Principle IX.* The mathematical expectation is not a sufficient approximation to the actual phenomenon of the mind, when benefits depend upon very small probabilities; even when the fortune of the player forms no part of the consideration. A great number of mathematical laws might be proposed as hypothetical representatives of the *law of expectation*; but there are no direct means of submitting them to experiment.

(42.) In (38.) it must be observed that we have only compared the proportions in which the risks of different persons are to be adapted to their fortunes. But in considering the value of the different parts of a person's fortune to himself, it is evident that the first shilling risked is of less value than the second, and so on. If we suppose F the amount which an individual should not risk at all, and F' the rest of his fortune, $F+F'$ in all, and if we divide F' into n parts, each equal to dx , and so great in number that dx is small, the values of the successive equal portions, estimated by the proportions they bear to the amount left, will be

$$\frac{m dx}{F+F'-dx}, \frac{m dx}{F+F'-2dx}, \dots, \frac{m dx}{F+F'-n dx} \text{ or } \frac{dx}{F},$$

where m is a constant to be determined.

If we diminish dx and increase n , without limit, we have by known principles the value of the first portion R of F' in the formula

$$m \int_0^R \frac{dx}{F+F'-x}, \text{ or } m \log \frac{F+F'}{F+F'-R} = M_R.$$

If we consider the value of all that it is right to risk as unity, we have, making $R=F'$,

$$m \log \frac{F+F'}{F} = 1, \quad M_R = \frac{\log(F+F') - \log(F+F'-R)}{\log(F+F') - \log(F)};$$

which is, on the preceding suppositions, the moral value of R pounds to a person who has $F+F'$, of which F' is the largest portion he ought to risk. The suppositions entirely depend upon that of the value of a small sum being inversely as the rest of the fortune; if this be admitted, all the rest is demonstration. From the formula, it is evident that any species of logarithms may be chosen.

Thus if a man may risk half his fortune, or if $F=F'$, and if $R=\frac{1}{2}F$, the moral value of the first half is

$$\frac{\log 2 - \log 1\frac{1}{2}}{\log 2}, \text{ or about } .42.$$

With these principles we shall now proceed to some cases of simple mathematical probabilities.

(43.) *PROBLEM.* If two common dice be thrown, what is the probability that the sum of the two numbers thrown is n , which of course is not less than 2, or more than 12?

We have said that mathematics is in this subject only an abbreviator of operations. To show this we shall first solve the problem by inspection, and then apply a method. The possible throws are as follows; all but the doublets (*) may occur in two different ways.

* It is recorded somewhere or other that the pendulum of a clock once revolted, upon the ground of the enormous number of times it had to vibrate in one year; but was appeased by one of the weights, a more solid thinker, who reminded it that it would have just as enormous a number of seconds to vibrate in. Report also says, that not only did the pendulum return to its duty, but that it never went too fast or too slow again; a commendable example for our readers and ourselves.

1+4=5	2+5=7	*4+4=8	
1+5=6	2+6=8	4+5=9	
1+6=7	*3+3=6	4+6=10	

Theory of
Pro-
babilities.

The probability in favour of 2 is $\frac{1}{36}$ 5 is $\frac{4}{36}$ 8 is $\frac{5}{36}$ 11 is $\frac{2}{36}$
 3 is $\frac{2}{36}$ 6 is $\frac{5}{36}$ 9 is $\frac{4}{36}$ 12 is $\frac{1}{36}$
 4 is $\frac{3}{36}$ 7 is $\frac{6}{36}$ 10 is $\frac{3}{36}$

If we now consider the expression

$$x + x^2 + x^3 + x^4 + x^5 + x^6, \text{ or } x \frac{1-x^6}{1-x},$$

and multiply it by itself, the rule of multiplication (*addition* of exponents) combined with reasoning similar to that in (11.) shows us that so many times as x^n appears in the result, so many ways can n be formed by a couple taken out of 1, 2, 3, 4, 5, 6, with repetition. But

$$\left(x \frac{1-x^6}{1-x}\right)^2 = x^2 (1-2x^6+x^{12}) (1+2x+3x^2+\dots) \\ = x^2 + 2x^3 + 3x^4 + \&c.$$

by actual multiplication. The whole number of cases is 6^2 , or 36, of which 3 (the coefficient of x^3 in the preceding) favour the production of 2; whence the result in this case. This is not properly an abbreviated process in this simple instance; but it leads to the two following theorems, which will afterwards be of the highest utility.

If there be a ways of drawing a number α , b of drawing a number β , &c., all equally probable, then the probability of drawing a set of n counters, the sum of the numbers on which shall be p , is the coefficient of x^p in the development of $(ax^\alpha + bx^\beta + \dots)^n$.

The same theorem applies when any of the set α , β , &c. are negative, provided counters so marked are to be subtracted.

We shall now choose a problem in which this method will be an abbreviation and a security.

What is the chance of throwing 10 on three dice of 10 faces marked from 1 to 10? *Answer.* The number of ways is the coefficient of x^{10} in the development of

$$(x + x^2 + x^3 + \dots + x^{10})^3 \text{ or } x^3 (1-x^{10})^3 (1-x)^{-3},$$

or

$$x^3 (1-3x^{10}+3x^{20}-x^{30}) (1+3x+6x^2+10x^3+\dots).$$

This is the coefficient of x^7 in the latter term, or 36.

But the whole number of possible cases is 10^3 , or 1000, whence $\frac{9}{250}$, or nearly 1 to 27, is the probability in favour of the event.

The preceding method may be thus simplified. It is clear that the number of ways in which p can be the sum of n drawings out of 1, 2, 3, ... is exactly the same as the number of ways in which $p-n$ can be the sum of n drawings out of 0, 1, 2, 3, ..., and also that the number of ways in which a given sum can be drawn from m counters does not depend upon the number of these counters, unless some be wanting which may enter into that sum.

For example, if we would know in how many ways 30 can be drawn in four trials out (1, 2, ..., 27) and (1, 2, ..., 20), we have two different problems: there are ways of making thirty from four drawings of the first which do not exist in the second. But if we ask for the *number of ways* of drawing thirty in four trials from (1, 2, ..., 40) and (1, 2, ..., 100), the two problems are the same, as is sufficiently evident. But it is clear that the *probabilities* of drawing thirty are less in the second than in the first. In talking of a die of ten faces we mean that there are to be supposed ten ways of obtaining a number, all equally probable. A prism of ten sides, with ends too small to allow of its falling with either end upwards, would answer the purpose.

(44.) We shall now apply the resources of mathematics to the general problem, and shall proceed, in the manner of Laplace, to point out the application to some phenomena of the material universe.

Let there be $n+1$ counters, marked 0, θ , 2θ , 3θ , ..., $n\theta$; one is drawn and put back again; and so on. What is the probability that i drawings will give $s\theta$, s being a whole number? This is evidently the same problem as finding the probability of drawing s in i drawings from 0, 1, 2, ..., n .

* We have followed Mr. Lubbock (*Probability, Lib. Useful Knowl.*) in substituting the principles just laid down for the very unwieldy method of Laplace, which nevertheless is an excellent deduction from something like inspection of cases.

While on this subject we may state, that though we should in any case have thrown aside most of the problems on gambling which usually fill works on our subject, in order to make room for those principles which "have contributed much to the accuracy of modern astronomy;" yet we do this with the more satisfaction, that there exists in our language such a collection of these problems, and in so accessible a form, as that given by Mr. Lubbock. They have the additional advantage of having been, to all appearance, selected more with a view to show the manner in which mathematics may be applied, than on account of any value attached to the chances of a card or a die, considered as a result.

Theory of
Pro-
babilities.

The result required is the coefficient of x^s in the developement of $(x^0 + x^1 + x^2 + \dots + x^n)^i$ or $(1 - x^{n+1})^i$ or $(1 - x)^{-i}$, or the product of the two series

Theory of
Pro-
babilities.

$$1 - ix^{n+1} + \frac{i(i-1)}{2} x^{2n+2} - \frac{[i, i-2]}{[3]} x^{3n+3} + \&c.$$

$$1 + ix + \frac{i(i+1)}{2} x^2 + \frac{[i, i+2]}{[3]} x^3 + \frac{[i, i+3]}{[4]} x^4 + \&c.;$$

where, as before, $[i, i+z]$ means $i(i+1) \dots (i+z)$, $[z]$ means $1 \cdot 2 \cdot 3 \dots z$,

we wish to extract the term Sx^s from the product of the preceding, and we must therefore ask in what ways s can be made by taking one out of each of the sets

$$\begin{array}{cccccc} 0 & n+1 & 2n+2 & 3n+3 & \&c. \\ 0 & 1 & 2 & 3 & \&c. \end{array}$$

or to find all the solutions of $V(n+1) + W = s$, where V and W are whole numbers (0 being included.) This gives

Exponent from first series.	Exponent from second series.	Corresponding coefficient of x^s .
$V=0$	$W=s$	$1 \times \frac{[i, i+s-1]}{[s]}$
$V=1$	$W=s-n-1$	$-i \times \frac{[i, i+s-n-2]}{[s-n-1]}$
$V=2$	$W=s-2n-2$	$i \frac{(i-1)}{2} \frac{[i, i+s-2n-3]}{[s-2n-2]}$

and so on, up to

$V = \text{whole number next below } \frac{s}{n+1}, \text{ say } v;$

$$W = s - vn - v; \text{ giving } \pm \frac{[i, i-v+1]}{[v]} \cdot \frac{[i, i+s-nv-v-1]}{[s-nv-v]}$$

The sum of these $v+1$ terms is the coefficient required, or the number of ways of drawing s in i trials from $0, 1, \dots, n$; and this divided by $(n+1)^i$, the whole number of possible drawings, gives for the probability of drawing s , $v+1$ terms of

$$\frac{1}{(n+1)^i} \left\{ \frac{[i, i+s-1]}{[s]} - i \frac{[i, i+s-n-2]}{[s-n-1]} + \frac{i(i-1)}{2} \frac{[i, i+s-2n-3]}{[s-2n-2]} + \dots \right\}$$

which, by the application of the formula

$$\frac{[i, z+n]}{[z]} = \frac{[z+n]}{[i-1] \cdot [z]} = \frac{[z+1, z+n]}{[i-1]},$$

(which gives a common denominator) becomes $v+1$ terms of

$$\frac{1}{[i-1](n+1)^i} \left\{ [s+1, s+i-1] - i[s-n, s+i-n-2] + i \frac{i-1}{2} [s-2n-1, s+i-2n-3] - \&c. \right\}$$

As an instance, suppose we ask in how many ways 25 can be drawn from three drawings of $0, 1, \dots, 10$. Here $i=3, n=10, s=25$, and $v=2$; therefore the term in brackets ($v+1=3$) is

$$[26, 27] - [15, 16] \times 3 + [4, 5] \times \frac{3 \cdot 2}{2}, \text{ or } 42;$$

which divided by $[i-1]$ or 1.2 gives 21 for the number of ways in question, which may be easily verified by observing that $10+10+5$ may be drawn in *three* ways; $10+9+6$ in *six* ways; $10+8+7$ in *six* ways; $9+9+7$ in *three* ways; $9+8+8$ in *three* ways; and $3+6+6+3+3=21$. But $(n+1)^3=1331$; therefore the probability required is $\frac{21}{1331}$.

(45.) Now let us suppose the number n to be increased without limit, and θ , the *unit of the counters*, to be diminished without limit, in such manner that $n\theta$, the highest drawing, shall always be N ; and let s at the same time increase without limit, so that $s\theta$ shall always be S . The common method of the integral calculus shows that we must thus obtain the infinitely small probability* of obtaining *exactly* S for the sum of i drawings, where each drawing may give *any thing* between 0 and N , and all intermediate quantities have equal probabilities. It is evident that each product within the $\{ \}$ has $i-1$ terms, which, severally, as s increases without limit, approximate to s , in the first product, to $s-n$ in the second, to $s-2n$ in the third, and to $s-vn$ in the last; v being

* If we should suppose a point to be thrown at a straight line, all points of which it has the same chance of hitting, it is plain that the probability of hitting any given point in a finite number of trials is infinitely small. If we were here advocating the theory of infinitely small quantities, (which we only use as an abbreviation of language,) we should say that we have a conception upon which the mind can found a notion of *infinitely small* as distinguished from *nothing*. No one can say there is *no probability whatsoever* of hitting a given point; while it is clear there is only one case in favour of it against an infinite number of unfavourable cases.

Theory of
Pro-
babilities.

the whole number next below $\frac{s}{n+1}$, or $\frac{s\theta}{n\theta+\theta}$, or $\frac{S}{N+\theta}$, or $\frac{S}{N}$, since θ diminishes without limit. Hence the preceding probability continually approaches to $v+1$ terms of

Theory of
Pro-
babilities.

$$\frac{1}{[i-1](n+1)} \left\{ \left(\frac{s}{n+1} \right)^{i-1} - i \left(\frac{s-n}{n+1} \right)^{i-1} + i \frac{i-1}{2} \left(\frac{s-2n}{n+1} \right)^{i-1} - \&c. \right\},$$

which itself may have the first factor written in the form $\frac{\theta}{[i-1](N+\theta)}$, and (multiplying the numerators and denominators of the fractions in the $\{ \}$ by θ) may be shown to approach to a ratio of equality with $v+1$ terms of

$$\frac{\theta}{[i-1]N} \left\{ \left(\frac{S}{N} \right)^{i-1} - i \left(\frac{S}{N} - 1 \right)^{i-1} + i \frac{i-1}{2} \left(\frac{S}{N} - 2 \right)^{i-1} - \&c. \right\}.$$

Now θ is the differential of S , for the possible drawing next higher than S or $s\theta$ is $(s+1)\theta$ or $S+\theta$, $\therefore \theta = dS$; and we have thus the infinitely small probability in question. To determine the probability of the i drawings giving a total between 0 and a certain specific value of S , we must add the probabilities of each of the several cases, 0, dS , $2dS$, &c., up to the specific value; that is, we must integrate the preceding expression with respect to S from $S=0$ up to S = the specific value; which gives for the said probability (i resulting in the denominator from each integration, changing $[i-1]$ into $[i]$) $v+1$ terms of

$$\frac{1}{[i]} \left\{ \left(\frac{S}{N} \right)^i - i \left(\frac{S}{N} - 1 \right)^i + i \frac{i-1}{2} \left(\frac{S}{N} - 2 \right)^i - \&c. \right\}.$$

If $\frac{S}{N}$ be a whole number, it is plain from the original investigation that v is that whole number. If we then propose to find the probability of three drawings giving a total between 0 and $3N$, we must take $S=3N$, $v=3$, $i=3$, which gives

$$\frac{1}{2 \cdot 3} \{ 3^3 - 3 \cdot 2^3 + 3 \cdot 1^3 - 1 \cdot 0^3 \}, \text{ or } 1;$$

that is, *certainty*, which is evidently true. Let the student deduce this mathematical theorem independently;

$$[i] = i^i - i(i-1)^i + i \frac{i-1}{2} (i-2)^i - \&c.,$$

which is here the means of indicating the certainty of i throws, each between 0 and N , giving not more than iN

(46.) There are ten planets, besides the earth, the orbit of which is the ecliptic. Each of these ten planets has an orbit inclined in a certain degree to the ecliptic. The inclinations of these ten orbits are so small that their sum is only $91^\circ 41' 87''$ (French metrical system) less than one alone might be (100°), if the orbits of the planets were the work of chance.

Suppose it possible that these ten inclinations were not dependent on any cause, but that they were formed in a manner which would render any one inclination from 0° to 100° as likely as another. What then is the probability that we should have ten inclinations, the total of which is under 92° . In this case $S=92^\circ$, $N=100^\circ$, $v=0$, and the first term of the formula gives

$$\frac{1}{[10]} \left(\frac{92}{100} \right)^{10}, \text{ or } .00000012;$$

and if there be a reason for the inclinations being as described, the probability of the event is 1. Consequently it is 1 : .00000012, or about ten million to one that there was a necessary cause in the formation of the solar system for the inclinations being what they are. The same reasoning, applied to all the observed comets, does not give any ground for suspecting that their inclinations are similarly circumstanced.

(47.) If we suppose the ratio of the probabilities of drawing exactly P and P' (lying between 0 and N) in single trials to be p and p' , then the probability of drawing between P and $P+dP$ in a single trial must be proportional to $p dP$. If we consider p itself as a function of P , and dP as infinitely small, then any variation of probability between P and $P+dP$ will itself be infinitely small, and may be disregarded in connection with p . This principle is precisely the same as that by which, P representing the accelerating force on a particle, $P dm$ represents the moving force on the element dm .

If, then, we wish to know the probability of a drawing lying between a and b , we must integrate $p dP$ from $P=a$ to $P=b$, which we can do when p is a known function of P . For instance, if the probability of drawing exactly P be aP^2 for any value of P between 0 and N , we must have $\int_0^N aP^2 dP = 1$, if there be certainty of drawing between 0 and N , or $aN^3 = 3$: so that it is a rational supposition to lay down the case, that a drawing may be any where between 0 and N with a probability of $\frac{3P^2}{N^3}$ for the drawing being between P and $P+dP$. And the probability of drawing between a and $a+k$ is therefore

$$\frac{3}{N^3} \int_a^{a+k} P^2 dP, \text{ or } \frac{(a+k)^3 - a^3}{N^3}.$$

In just the same way, if there be two drawings, and the probabilities of their severally giving results between P and $P+dP$ and Q and $Q+dQ$ be $p dP$ and $q dQ$, the probability of both events taking place is $p q dP dQ$, from which may be found by integration the probability of both drawings lying between given pairs of limits.

Theory of
Pro-
babilities.

There is no need to insist on the various ways in which the integrations may be required to be made, as they are all sufficiently considered in the applications of the integral calculus to geometry.

Theory of
Pro-
babilities.

(48.) We now come to the question of ascertaining how to judge of the probability of future events from those which are past, on the supposition that the circumstances which produced the latter continue in force. This must be the practical problem in all cases; for we cannot command urns with a given proportion of black and white balls, nor can we open those which circumstances present, but must be content to draw what we can, and form our conclusions as to those which are to come from our experience of those which have appeared. This, as explained in (19.), must be done by referring the event to every possible cause, deducing the probability of each cause from the event, and then deducing the probability of the coming event from each of the possible causes.

PROBLEM. There is an urn containing counters marked W, X, Y, and Z. Of $m+n+p+q$ single drawings, (restoring each drawing again,) m were marked W, n were marked X, p were marked Y, and q were marked Z. What is the probability that in the next $m'+n'+p'+q'$ drawings m' shall be marked W, n' shall be marked X, &c., supposing that we have no reason whatever to imagine the contents to be in any one ratio rather than another, except what we gather from the observed event? *we are, however, supposed to know that either W, X, Y, or Z must come out.*

Let $w, x, y,$ and z be the probabilities of drawing W, X, Y, and Z at one throw. Then

$$w+x+y+z=1; \quad (1)$$

and the probability of the observed event is $w^m x^n y^p z^q$, for their coming out in any assigned order. But the whole number of possible orders is (10.) $[m+n+p+q]$ divided by $[m]. [n]. [p]. [q]$, which call A. Then $A w^m x^n y^p z^q$ is the probability of the observed event. Now let us suppose that $w, x, y,$ and z may be severally taken out of the sets $\omega, 2\omega, \dots$ &c. *ad inf.* $\xi, 2\xi, \dots$ &c., $\eta, 2\eta, \dots$ &c., $\zeta, 2\zeta, \dots$ &c., in any manner consistent with equation (1). This gives for the probability of w, x, y, z , being the real proportions, the fraction

$$\frac{A w^m x^n y^p z^q}{\sum A w^m x^n y^p z^q}, \text{ or } \frac{w^m x^n y^p z^q}{\sum w^m x^n y^p z^q}, \text{ which call } \frac{P}{\sum P},$$

in the denominator of which (19.) every possible state of the numerator is a term. If we multiply numerator and denominator by $\omega \eta \xi$, and then diminish the three factors without limit, which, as in the last problem, is equivalent to representing the last product by $dw dx dy$, we find the preceding become $\frac{P dw dx dy}{\int P dw dx dy}$; which, since the inte-

gration is to be made for every possible value of $w, x, y,$ and z or $1-x-y-w$, gives the following: suppose w and x constant, and integrate with respect to y from $y=0$ to $y=1-w-x$; then suppose w constant, and integrate with respect to x from $x=0$ to $x=1-w$; thirdly, integrate with respect to w from $w=0$ to $w=1$.

LEMMA.

$$\int_0^a v^m (a-v)^n dv = [m] \cdot [n] \div [m+n+1] \times a^{m+n+1}.$$

For

$$\int v^m (a-v)^n dv = \frac{v^{m+1} (a-v)^n}{m+1} + \frac{n}{m+1} \int v^{m+1} (a-v)^{n-1} dv.$$

Call the required integral between the given limits $V_{m,n}$; then

$$V_{m,n} = \frac{n}{m+1} V_{m+1,n-1} = \frac{n(n-1)}{(m+1)(m+2)} V_{m+2,n-2}$$

$$\dots = \frac{[n]}{[m+1, m+n]} \{ V_{m+n,0}, \text{ or } \int_0^a v^{m+n} dv \};$$

whence

$$\int_0^a v^m (a-v)^n dv = \frac{[m][n]}{[m+n+1]} a^{m+n+1};$$

because

$$\frac{[n]}{[m+1, m+n]} \frac{1}{m+n+1} = \frac{[m][n]}{[m+n+1]}$$

The steps of the application of the lemma are as follows:

Integrate	from	to	which gives
$y^p (1-w-x-y)^q dy$	$y=0$	$y=1-w-x$	$\frac{[p][q]}{[p+q+1]} (1-w-x)^{p+q+1}$
$x^n (1-w-x)^{p+q+1} dx$	$x=0$	$x=1-w$	$\frac{[n][p+q+1]}{[n+p+q+2]} (1-w)^{n+p+q+2}$
$w^m (1-w)^{n+p+q+2} dw$	$w=0$	$w=1$	$\frac{[m][n+p+q+2]}{[m+n+p+q+3]}$

whence the denominator required is $\frac{[m][n][p][q]}{[m+n+p+q+3]} = \frac{1}{C}$; or the probability of w, x, y, z being the proportions

of the counters, is $C w^m x^n y^p z^q dw dx dy dz$. If this were certain, the probability of the proposed prospect in a given order would be $w^{m'} x^{n'} y^{p'} z^{q'}$, therefore the probability that the prospect will be realized from this cause only is (20.) $A' \times C w^{m+m'} x^{n+n'} y^{p+p'} z^{q+q'} (1-w-x-y)^{q+q'} dw dx dy$, where A' is (what A was to the observed event) the number of orders in which the prospect may be realized, namely, $[m'+n'+p'+q'] \div [m'][n'][p'][q']$; and therefore, to find the whole probability, taking every possible cause into account, this must be integrated in the same manner as the preceding, which gives (restoring A' and C)

Theory of
Pro-
babilities.

or

$$\frac{[m'+n'+p'+q']}{[m'] [n'] [p'] [q']} \frac{[m+n+p+q+3]}{[m] [n] [p] [q]} \frac{[m+m'] [n+n'] [p+p'] [q+q']}{[m+n+p+q+m'+n'+p'+q'+3]},$$

$$\frac{[m'+n'+p'+q']}{[m'] [n'] [p'] [q']} \frac{[m+1, m+m'] [n+1, n+n'] [p+1, p+p'] [q+1, q+q']}{[m+n+p+q+4, m+n+p+q+m'+n'+p'+q'+3]}.$$

Theory of
Pro-
babilities.

It is evident that 3 will be replaced by $i-1$, when there are i sorts.

Suppose, for instance, the first six drawings have given four white and two black balls, (assuming only white and black to be possible,) what is the probability that the next two balls shall be both white, or both black, or white and black? These three cases suppose

$$\begin{array}{lll} i=2 & i-1=1 \\ \text{I. } m=4 & n=2; & \text{both white} \dots m'=2 \quad n'=0 \\ \text{II. } m=4 & n=2; & \text{white and black} \quad m'=1 \quad n'=1 \\ \text{III. } m=4 & n=2; & \text{both black} \dots m'=0 \quad n'=2 \end{array}$$

$$\begin{array}{lll} \text{I. } \frac{2 \cdot 1}{2 \cdot 1} \frac{[7]}{[4] [2]} \cdot \frac{[6] [2]}{[9]} = \frac{30}{72} \\ \text{II. } \frac{2 \cdot 1}{1 \cdot 1} \frac{[7]}{[4] [2]} \frac{[5] [3]}{[9]} = \frac{30}{72} \\ \text{III. } \frac{2 \cdot 1}{2 \cdot 1} \frac{[7]}{[4] [2]} \frac{[4] [4]}{[9]} = \frac{12}{72}; \end{array}$$

these are the probabilities of the three cases; their sum is unity, as the hypothesis requires.

The general formula is as follows; let there be i sorts, and let the observed event be m_1 of the first, m_2 of the second, &c., and the prospect of which the probability is required be m'_1 of the first, m'_2 of the second, &c. Let Σm and $\Sigma m'$ denote the number of drawings made and to be made: then the probability which the observed event gives to the proposed is

$$\frac{[\Sigma m']}{[m'_1] \dots [m'_i]} \cdot \frac{[m_1+1, m_1+m'_1] \dots [m_i+1, m_i+m'_i]}{[\Sigma m+i, \Sigma m+\Sigma m'+i-1]}.$$

Thus if the prospect be that of drawing one ball of the r th species, the probability is $\frac{m_r+1}{\Sigma m+i}$.

(49.) There remains, however, an important case not yet considered; suppose that having obtained i sorts in Σm drawings, and i sorts only, we do not take it for granted that these are all the possible cases, but allow ourselves to imagine there may be sorts not yet come out. This requires that in the integration we should not suppose z to be $1-w-x-y$, but treat it as an independent variable, subject only to the condition that its limits of variation must be 0 and $1-w-x-y$. That is, integrate between these limits before substitution, or begin with $z^{i+1} \div (q+1)$ instead of z^i , introducing $dw dx dy dz$ as a factor of the numerator and denominator, instead of $dw dx dy$. This process changes the result in nothing but substituting $i+1$ for i in the last denominator, and gives

$\frac{m_r+1}{\Sigma m+i+1}$ for the probability of the next drawing being of the r th sort; adding together therefore the probabilities of the first drawing in prospect being of either of the sorts already obtained, we find *not* certainty, as before, but $(\Sigma m+i) \div (\Sigma m+i+1)$, leaving one chance against $\Sigma m+i$ that the new sort may be different from any preceding. Therefore we have this theorem:

Judging of future events from the past, and in no other manner whatsoever, if Σm observed events show i varieties, it is $\Sigma m+i$ to 1 that the next event shall be a repetition of some one preceding; and, *ceteris paribus*, the greater the number of varieties the more probable is it that no others will happen. But the last part of this theorem may be mistaken. Do we mean to say, for instance, that if a continued succession of drawings gave 1, 2, 3 . . . up to 1000, it would be more probable that the next should be a repetition of some preceding number (and not 1001) than it would have been when we had only drawn 1, 2? In asking this question, the reader is taking the word event in a wrong sense. He is turning his ideas from the mere *drawing of a number* to a *relation between two successive numbers*, and constituting the latter the event in question, while he wonders at a conclusion drawn from the former. Let the *succession* not have been observed, but only the numbers, and then $\Sigma m=1000$, $i=1000$, and it is* 2000 to 1 upon this observed event that the 1001st drawing will be a repetition. But let him have observed the succession; that is, let the observed event be the repetition of the one event, *ordinal succession*; and 1. The very number of events observed is different, being 999 and not 1000. 2. Since $i=1$ and $\Sigma m=999$, it is 1000:1 in favour of *one more* succession; and the same conclusion would have been obtained if the continual difference of each drawing from the preceding had been the event observed. We are here met by the same difficulty which we stated in (15.), namely, the necessity of considering the combined probability arising from an event having different probabilities when considered in different relations, or as the result of different trains of inference. We have now got beyond the point within which we are prepared to try the results of our theory by our own impressions, or those of mankind in general. Cases so complicated as the choice out of an infinite number of causes, to be made according to the several probabilities of their yielding an observed event, are beyond the reach of unassisted judgment. Whether the mathematical theory of probabilities be a good and trustworthy guide may be a question: but it is not to be opposed on the strength of any independent impressions which exist

* We must again warn the reader that probabilities are in his mind, not in the urn from which he draws.

Theory of Probabilities. upon suppositions so complicated as those we have entered into. Let us take the theory of probabilities itself upon probability; if there be an even chance that its principles are trustworthy, we have then a full even chance that the consequences are the same; for though remote, they are connected with the first principles by absolute demonstration. Theory of Probabilities.

(50.) We shall now take some problems involving complicated possibilities, not so much for the sake of numerical solutions, as of showing various methods by which the difficulty is reduced to a purely mathematical form.

PROBLEM. Two players, A and B, of equal skill, want x and y points of winning a game, and whichever makes up his points first, wins. What are the probabilities in favour of each?

Let $\phi(x, y)$ be A's probability; if he win the next game (of which the chance is $\frac{1}{2}$) his chance will then be $\phi(x-1, y)$, and therefore of his winning the first point, and winning finally, the chance is $\frac{1}{2}\phi(x-1, y)$; similarly, of his losing the first point, and of winning the game, his chance $\frac{1}{2}\phi(x, y-1)$. But the sum of the two latter probabilities makes up his present chance; therefore

$$\phi(x, y) = \frac{1}{2}\phi(x-1, y) + \frac{1}{2}\phi(x, y-1) \dots (1).$$

Now imagine that $\phi(x, y)$ is the coefficient of $t^x v^y$ in a developement which contains all whole values of x and y , such as $\phi(0, 0) + \phi(0, 1)v + \phi(1, 0)t + \dots + \phi(x, y)t^x v^y + \dots$

Let this function be $\psi(t, v)$, or $\sum \phi(x, y)t^x v^y$; then it is plain that $t\psi(t, v)$ and $v\psi(t, v)$ will have for their developements

$$\begin{aligned} \sum \phi(x-1, y)t^x v^y & (\sum \text{not containing terms in which } x=0) = t\psi(t, v), \\ \sum \phi(x, y-1)t^x v^y & (\sum \text{not containing terms in which } y=0) = v\psi(t, v); \end{aligned}$$

whence (if $x > 0, y > 0$, both restrictions being made)

$$\begin{aligned} \psi(t, v) - \frac{1}{2}t\psi(t, v) - \frac{1}{2}v\psi(t, v) &= \sum \left(\phi(x, y) - \frac{1}{2}\phi(x, y-1) - \frac{1}{2}\phi(x-1, y) \right) t^x v^y \quad (x > 0, y > 0) \\ &+ \left\{ \begin{array}{l} \text{sum of terms of } \sum \phi(x, y)t^x v^y \text{ omitted by omitting severally } x=0, y=0, \\ \text{or } \phi(0, 0) + \phi(0, 1)v + \phi(0, 2)v^2 + \dots \\ \quad + \phi(1, 0)t + \phi(2, 0)t^2 + \dots \end{array} \right\} \\ &- \left\{ \begin{array}{l} \frac{1}{2} \text{ sum of terms of } \sum \phi(x-1, y)t^x v^y \text{ omitted by omitting } y=0, \\ \text{or } \phi(0, 0)t + \phi(1, 0)t^2 + \dots \end{array} \right\} \\ &- \left\{ \begin{array}{l} \frac{1}{2} \text{ sum of terms of } \sum \phi(x, y-1)t^x v^y \text{ omitted by omitting } x=0, \\ \text{or } \phi(0, 0)v + \phi(0, 1)v^2 + \dots \end{array} \right\} \end{aligned}$$

But $\phi(0, 0) = 0$, there is no case in which both can win; $\phi(0, y) = 1$, A has actually won when he has no points left to gain; $\phi(x, 0) = 0$, A cannot win when B wins; and $\phi(x, y) - \frac{1}{2}\phi(x-1, y) - \frac{1}{2}\phi(x, y-1) = 0$ in all cases. The preceding therefore gives

$$\left(1 - \frac{1}{2}t - \frac{1}{2}v\right)\psi(t, v) = v + v^2 + \dots - \frac{1}{2}(v^2 + v^3 + \dots) = \frac{v\left(1 - \frac{1}{2}v\right)}{1-v},$$

or

$$\psi(t, v) = \frac{v\left(1 - \frac{1}{2}v\right)}{(1-v)\left(1 - \frac{1}{2}t - \frac{1}{2}v\right)},$$

in the developement which the coefficient of $t^x v^y$ is the probability required.

The developement of this in powers of t is

$$\frac{v}{1-v} \left\{ 1 + \frac{1}{2} \frac{t}{1 - \frac{1}{2}v} + \dots + \frac{1}{2^x} \frac{t^x}{\left(1 - \frac{1}{2}v\right)^x} + \dots \right\},$$

and the coefficient of v^y in $\frac{v}{1-v} \left(1 - \frac{1}{2}v\right)^{-x}$,

or

$$(v + v^2 + v^3 + \dots) \times \left(1 + x \frac{v}{2} + x \frac{x+1}{2} \frac{v^2}{4} + \dots\right)$$

is the sum of all the values of the coefficient of

$$v^\theta \times \frac{[x, x+\lambda-1]}{[\lambda]} \frac{v^\lambda}{2^\lambda},$$

where $\theta + \lambda = y$, from $\lambda = 0, \theta = y$, to $\lambda = y-1, \theta = 1$. This multiplied by 2^{-x} , is

Theory of
Pro-
babilities.

$$\frac{1}{2^x} \left\{ 1 + x \cdot \frac{1}{2} + x \frac{x+1}{2} \frac{1}{2^2} + \dots + \frac{[x, x+y-2]}{[y-1]} \frac{1}{2^{y-1}} \right\}.$$

Theory of
Pro-
babilities.

Suppose, for instance, $x=2, y=3$, and the game must be decided in five points at most. The orders favourable to A winning are AA, BAA, ABA, ABBA, BBAA, BABA, the several probabilities of which (the chances being even) are $\frac{1}{4}, \frac{1}{8}, \frac{1}{8}, \frac{1}{16}, \frac{1}{16}, \frac{1}{16}$, the sum of which is $\frac{11}{16}$. This will be also the result of the preceding expression; for when $x=2, y=3$, it becomes

$$\frac{1}{4} \left(1 + \frac{2}{2} + \frac{2 \cdot 3}{2} \frac{1}{4} \right) = \frac{22}{32} = \frac{11}{16}.$$

We have introduced the preceding problem that the student may be prepared* to admit the use of Laplace's *Theory of Generating Functions*, which we now proceed to describe. The preceding is a case in which its principles are applied. It may be stated in the following words. To find P_x a required function of x , where x is a whole number, endeavour to find the series of powers of t , which shall have $P_0, P_1, P_2, \&c.$ for coefficients of $t^0, t^1, t^2, \&c.$; that is, find ϕt the finite envelopment of $P_0 + P_1 t + P_2 t^2 + \&c.$ It will then follow that every method of developing ϕt will also be a method of expressing P_x . And ϕt is then called the *generating function* of P_x , (which we shall abbreviate into *generatrix*), and P_x we shall call the *generata* of ϕt . Similarly, when $\psi(t, v) = \sum P_{x,y} t^x v^y$, ψ is the *generatrix* of $P_{x,y}$, &c. The following theorems may now be easily proved.

1. When the generatrices are identical, but in different forms only, the same is true of the generatæ, and *vice versa*.

2. The generatrix of a sum or difference is the sum or difference of the generatrices. Thus if ϕt generate P_x , and χt generate K_x , then $\phi t \pm \chi t$ generates $P_x \pm K_x$; and if $\phi t = \psi t \pm \chi t$, and $\phi t, \psi t$, and χt severally generate P_x, Q_x , and R_x , then $P_x = Q_x \pm R_x$.

3. In the preceding case $\phi t \times \chi t$ generates $K_x P_0 + K_{x-1} P_1 + \dots + K_1 P_{x-1} + K_0 P_x$.

4. If ϕt generate P_x , then $t^n \phi t$ generates P_{x-n} , beginning from $x=n$ inclusive upwards.

5. Let ϕt generate P_x , then $t^{-n} \phi t$ generates 1. the series $\frac{P_0}{t^n} + \frac{P_1}{t^{n-1}} + \dots + \frac{P_{n-1}}{t}$; 2. P_{x+n} for all values of x .

Observe, that the phrase " ϕt generates P_x " means that, x being a whole number, $P_x t^x$ is the only term of the development which contains t^x ; that is, $P_0 + P_1 t + P_2 t^2 + \&c.$ is the whole of the development, so far as whole powers are concerned. But this has no relation to any negative or fractional powers: consequently, we may not say conversely that if ϕt generate P_x , therefore the generatrix of P_x is ϕt ; for ϕt is only one of the generatrices of P_x ; others are contained in $\phi t + \psi t$, if ψt do not admit of expansion, wholly or partially, in whole powers of t . When we pass from a generatrix to the generata, the process is direct; but the passage from the latter to the former involves the addition of an arbitrary function, depending upon the particular circumstances of the case. A student who is used to the differential calculus in its various forms will easily seize this consideration. We shall now show an instance or two of the application of this theory.

Let ϕt generate P_x , then $\frac{1}{t} \phi t$ generates P_{x+1} , and $\left(\frac{1}{t} - 1\right) \phi t$ generates $P_{x+1} - P_x$, or ΔP_x .

Similarly $\left(\frac{1}{t} - 1\right)^2 \phi t$ generates $\Delta P_{x+1} - \Delta P_x$, or $\Delta^2 P_x$, and $\left(\frac{1}{t} - 1\right)^n \phi t$ generates $\Delta^n P_x$. But

$$\left(\frac{1}{t} - 1\right)^n \phi t = \frac{1}{t^n} \phi t - n \frac{1}{t^{n-1}} \phi t + n \frac{n-1}{2} \frac{1}{t^{n-2}} \phi t - \&c.;$$

and therefore by theorem (2) preceding,

$$\Delta^n x = u_{x+n} - n u_{x+n-1} + n \frac{n-1}{2} u_{x+n-2} - \&c.,$$

a well known theorem. Similarly $\frac{1}{t^n} = \left\{ 1 + \left(\frac{1}{t} - 1\right) \right\}^n$ expanded gives $u_{x+n} = u_x + n \Delta x + \&c.$; and to use the words of Laplace, which contain a theorem more easily deducible from first principles than any other of the same extent, "*Toutes les manières de développer la puissance $\frac{1}{t^r}$, donnent autant de manières différentes d'interpoler les suites.*"

For example, suppose it required to express P_{x+i} in terms of $P_x, \Delta P_x, \Delta^2 P_x, \&c.$ We can do this the moment we have expanded $\frac{1}{t^i}$ in powers of $\left(\frac{1}{t} - 1\right) t^r$. Let this be α ; then $\frac{1}{t} = 1 + \alpha \left(\frac{1}{t}\right)^r$: use Lagrange's theorem to develop $\left(\frac{1}{t}\right)^i$; pass from the generatrices to the generatæ, and we have

$$P_{x+i} = P_x + i \Delta P_x + \frac{i(i+2r-1)}{2} \Delta^2 P_x + \dots + \frac{i(i+n-1) \dots (i+n-1)}{2 \cdot 3 \cdot 4 \dots n} \Delta^n P_x + \&c.$$

* Is not the neglect of this theory a consequence of the introduction of it into books without any results of application except such as have been already obtained without it?

Theory of
Probabilities.

(51.) We have found that $\left(\frac{1}{t}-1\right)^n \phi t$ generates $\Delta^n P_x$, when n is a positive whole number. let us examine the consequences of supposing $n = -1$. In that case

Theory of
Probabilities.

$$\left(\frac{1}{t}-1\right)^{-1} \phi t = \{t+t^2+t^3+\dots\} \{P_0+P_1 t+P_2 t^2+\&c.\} \\ = P_0 t + (P_0+P_1) t^2 + (P_0+P_1+P_2) t^3 + \&c.$$

But $\Sigma P_x = P_0 + P_1 + \dots + P_{x-1}$; therefore $\left(\frac{1}{t}-1\right)^{-1} \phi t$ generates ΣP_x . If we extend the theorem with respect to $\Delta^n P_x$ to the case of negative whole numbers, we see that it is necessary that $\Delta^{-1} P_x$ should stand for ΣP_x .

Let $T = a_0 + a_1 t + a_2 t^2 + \dots + a_n t^n$, $a_0, a_1, \&c.$ being constants. Then if ϕt generate P_x , it will be found that $T \phi t$ generates $a_0 P_x + a_1 P_{x-1} + \dots + a_n P_{x-n}$, from $x = n$ upwards; or universally, if we suppose P_x to stand for zero whenever x is negative. In fact, the series $T \phi t$ is $a_0 P_0 + (a_0 P_1 + a_1 P_0) t + \dots + \Sigma (a_0 P_x + \dots + a_n P_{x-n}) t^x$, where Σ includes all values of x from n inclusive upwards. If, then, we suppose P_x to be such a function that $a_0 P_x + a_1 P_{x-1} + \dots + a_n P_{x-n} = 0 \dots (1)$, for all values of x from n upwards, and if, moreover, we assume $a_0 P_0 = A_0$, $a_0 P_1 + a_1 P_0 = A_1$, $\&c.$ up to $a_0 P_{n-1} + \dots = A_{n-1}$, we have $T \phi t = A_0 + A_1 t + A_2 t^2 + \dots + A_{n-1} t^{n-1}$, and therefore this theorem: that the equation of differences (1) has for the value of P_x the genera of

$$\frac{A_0 + A_1 t + \dots + A_{n-1} t^{n-1}}{T},$$

where $A_0, A_1, \dots, A_{n-1}$ are the n arbitrary constants which it is known that integration must introduce.

In a similar way it may be proved of the function $P_{x,y}$, which satisfies the equation (from $x = n, y = n$ upwards) $a P_{x,y} + b P_{x-1,y} + c P_{x,y-1} + \dots$ up to $\{k P_{x-n,y} + \dots + s P_{x,y-n}\} = 0$, that it is the coefficient of $t^x v^y$ in the expansion of

$$\frac{A + B t + C v + \dots + (K t^{n-1} + \dots + S v^{n-1})}{a + b t + c v + \dots + (k t^n + \dots + s v^n)},$$

where $A, B, C, \&c.$ are indeterminate, or depend on the indeterminate constants.

(52.) PROBLEM. There are $n+1$ players, $C_1, C_2, \dots, C_{n+1}$, who toss a shilling together in this manner. C_1 first tosses with C_2 , the loser puts a shilling into a common stock, and the winner tosses with C_3 , the process being repeated. If C_1 beat all the rest, the game is finished; if not, the process goes on, each one coming in again in turn, till one has beat all the rest, one after another. What is the probability that this game will be finished at or before the x th throw? The player who wins at the x th throw must come into play for the last time against a winner, and at the $(x-n+1)$ th throw, which he must win, together with the $n-1$ following throws. This preceding winner has won either 1, 2, 3, $\dots$ or $n-1$ throws, not more, for he would then have won the game. Let $P_1, P_2, \dots, P_{n-1}$ be the probabilities that immediately previous to the $(x-n+1)$ th throw, the player in possession shall count 1, 2, 3, $\dots$, or $n-1$ throws won. Let m be a number not $> n-1$; then, if a player have won m throws, and win the remaining $n-m$, he wins the game; and if the former event have been completed in $x-n$ throws, he wins it, if at all, when $x-n+n-m$ (or $x-m$) throws have been made in all. The probability, therefore, of the game finishing in $x-m$ throws (being that of two events of which the probabilities are P_m and $\frac{1}{2^{n-m}}$) is $P_m \times \frac{1}{2^{n-m}}$; or if z_p be the probability that the game finishes in p throws, we have

$$P_m \times \frac{1}{2^{n-m}} = z_{x-m}, \text{ or } P_m = 2^{n-m} z_{x-m}.$$

The probability that a new player shall gain the $(x-n+1)$ th throw is $\frac{1}{2}$; and his chance of winning is evidently made up of the probabilities that he will win by entering against a player who counts 1, 2, 3, $\dots$, or $n-1$ throws. Hence that he will, 1. enter at the $(x-n+1)$ th throw against a player who has won m throws preceding; 2. win the $(x-n+1)$ th; 3. win the $n-1$ following, the probability is

$$P_m \times \frac{1}{2} \times \frac{1}{2^{n-1}}, \text{ or } 2^{n-m} z_{x-m} \times \frac{1}{2^n}, \text{ or } \frac{1}{2^m} z_{x-m};$$

the sum of these probabilities, for all values of m from 1 to $n-1$, is the total probability of his winning, or z_x ; therefore

$$z_x = \frac{1}{2} z_{x-1} + \frac{1}{2^2} z_{x-2} + \frac{1}{2^3} z_{x-3} + \dots + \frac{1}{2^{n-1}} z_{x-n+1} \dots (2)$$

Of this the solution z_x has for its generatrix (51.)

$$\frac{\psi t}{1 - 2^{-1} t - 2^{-2} t^2 - \dots - 2^{-n+1} t^{n-1}}, \text{ or } \frac{\psi t \left\{ 1 - \frac{1}{2} t \right\}}{1 - t + \left(\frac{t}{2} \right)^n},$$

where ψt is to be determined. If we develop the remaining factor (considering ψt as one) its first term is 1, consequently the lowest term of the product is the lowest term in ψt . Now, at first sight, it would appear as if the equation of differences gave $z_x = 0$: for it is obvious that the game cannot be won in $n-1$ throws or less;

Theory of
Pro-
babilities.

that is, $z_1=0, z_2=0 \dots z_{n-1}=0$, therefore (apparently) $z_n=0$ (z_n being from the equation (2) the sum of zeros.) But* the consideration on which the equation was formed excludes all supposition of the game being won at the n th throw; for the player who wins was supposed to enter against a player who had won one throw at least. Therefore the process counts from the $(n+1)$ th game. The generated series has no term corresponding to z_1 , and the $n-1$ constants depend on $z_2, z_3, \dots, z_n$: of which, by the conditions, all are zero except the last, which is

$\frac{1}{2^{n-1}}$, because the game is won if the player who wins the first game (be it either of the two) also win the $n-1$

succeeding games. Therefore, by making $\psi t = \frac{t^n}{2^{n-1}}$, as many terms of the complete series $z_1 t^1 + z_2 t^2 + \dots$ as there are arbitrary constants are made correct, and the developement will give the remainder. Now the probability of winning the game at or before the x th throw is made up of the probabilities of winning it at the n th, $n+1$ th, &c., up to the x th; that is, of $z_n + z_{n+1} + \dots + z_x$. But, as we have seen, if the series $z_n t^n + \dots$ be multiplied by $t + t^2 + \dots$ the coefficient of t^{x+1} will be $z_n + \dots + z_x$: multiply, therefore, by $1 + t + \dots$, or by $\frac{1}{1-t}$, and the coefficient of t^x will be the probability of winning at or before the x th throw. We have, therefore, to find the coefficient of t^x in

$$\frac{t^n}{2^{n-1}} \frac{1 - \frac{1}{2}t}{(1-t)\left(1-t+\frac{t^n}{2^n}\right)}$$

or that of t^x in

$$\frac{t^n}{2^n} \frac{2-t}{(1-t)(1-t+2^{-n}t^n)},$$

which is

$$\frac{1}{2^n} \frac{(2-t)t^n}{(1-t)^2} \left\{ 1 - \frac{2^{-n}t^n}{1-t} + \frac{2^{-2n}t^{2n}}{(1-t)^2} - \dots \right\}.$$

The r th term of the preceding developement (without its sign) is

$$\frac{1}{2^n} \frac{(2-t)t^n}{(1-t)^{r+1}} 2^{-rn+n}, \text{ or } \frac{1}{2^{rn}} \frac{(2-t)t^n}{(1-t)^{r+1}},$$

or

$$\frac{1}{2^{rn-1}} \frac{t^n}{(1-t)^{r+1}} - \frac{1}{2^{rn}} \frac{t^{n+1}}{(1-t)^{r+1}};$$

and the coefficient of t^x in this is

$$\frac{1}{2^{rn-1}} \frac{[r+1, r+x-rn]}{[x-rn]} - \frac{1}{2^{rn}} \frac{[r+1, r+x-rn-1]}{[x-rn-1]} \\ = \frac{1}{2^{rn}} \frac{[r+1, r+x-rn-1]}{[x-rn]} (x-rn+2r) = \frac{1}{2^{rn}} \frac{[x-rn+1, r+x-rn-1]}{[r]} (x-rn+2r),$$

and every term has a coefficient of t^x , for which x is greater than or equal to rn ; or as long as the whole number in $\frac{x}{n}$ is greater than or equal to r . Consequently the probability that the game in question will finish at or before

the x th throw is as many terms of the following series as there are units in the whole number next below $\frac{x}{n}$. (Explain the apparent anomaly in the first term, as found from the formula, by referring to the formula immediately preceding.)

$$\frac{x-n+2}{2^n} - \frac{(x-2n+1)}{1 \cdot 2 \cdot 2^{2n}} (x-2n+4) + \frac{(x-3n+1)(x-3n+2)}{1 \cdot 2 \cdot 3 \cdot 2^{3n}} (x-3n+6) - \&c.$$

If we suppose x to increase without limit, there is a set of terms (the highest powers of x in each) the ratio of which to the sum of the whole continually approximates to unity; namely,

$$\frac{x}{2^n} - \frac{x^2}{1 \cdot 2 \cdot 2^{2n}} + \frac{x^3}{1 \cdot 2 \cdot 3 \cdot 2^{3n}} - \&c., \text{ or } 1 - e^{-\frac{x}{2^n}}.$$

But this latter continually approximates to unity as x is increased without limit; consequently it is certain this game must finish if we are at liberty to continue it for any number of throws. This is a result which appears rather strange; but the extraordinary part is the phrase "it is certain." It would be better to say "it ought to be considered certain," because what has just been said proves the following:—If all the number of possible events in x throws were placed together, and those in which the game would have stopped be compared with those in which the game would not have stopped; then, by making x sufficiently great, the favourable cases may be made to exceed the unfavourable, as p to 1, where p is as great as we please. Play then a number of

* Laplace (p. 240) has omitted all allusion to this circumstance; and the omission is highly characteristic of his method of writing. No one was more sure of giving the result of an analytical process correctly, and no one ever took so little care to point out the various small considerations on which correctness depends. His *Théorie des Probabilités* is by very much the most difficult mathematical work we have ever met with, and principally from this circumstance: the *Mécanique Céleste* has its full share of the same sort of difficulty; but the analysis is less intricate.

Theory of
Pro-
babilities.

Theory of Pro-
babilities. throws so great that the ways in which there is a stoppage are 10,000,000,000,000 as great in number as the Theory of Pro-
babilities. ways in which there is none; and there is more certainty of the game being won somewhere in that number of
throws than of any event of common life which is in the smallest degree *problematical*, in any sense in which the
word is ever used. There are few events, of the happening of which to himself a man ever thinks, which
it is 10^{10} to 1 that he shall be able to avoid.

The preceding is highly illustrative of what we have said (23.) on *runs of luck*. In fact, it requires that some one player should have a run of n throws in his favour before this game is won. And it appears that, however great the number of players, the number of throws allowed may be made so much greater, as to make the chance of *some one* winning as near as we please to certainty. Those who are desirous of seeing the chance of any given player, and the value of it, may consult Laplace's *Théorie des Probabilités*, page 242, &c. We shall now take the wide question of the probability which skill gives to a run of luck, as the phrase is.

(53.) PROBLEM. Let q be the probability of a single event: required the probability of its having happened i times following at or before the x th throw. (The principal difference between this problem and the last, which if $q = \frac{1}{2}$ appear to be the same, lies in this, that every throw in the last puts some one or other one step towards the game; whereas here there is no step towards the game unless one given event happens.)

Let us first ask, what is the probability of such a run being just completed at the x th throw for the first time? The $(x-i)$ th throw must be unfavourable, or else the run of i , which is supposed not to have occurred before the x th, would in fact have occurred at the $(x-1)$ th. Prior to the following succession, (Y the event does happen, N it does not, the number of the throw being underneath,) .

N Y Y Y
..... $x-i$ $x-i+1$ $x-i+2$ x

the throws may be any whatever, provided there be no run of i . Again, the N immediately preceding the $(x-i)$ th throw may be either the $(x-i-1)$ th . . . up to the $(x-2i)$ th, but not further back, for reason as above. Now let P_m represent the probability of this compound event, that there shall have been no run of i successes preceding the $(x-i-m)$ th throw, and that the $(x-i-m)$ th shall be the first unfavourable throw next preceding the $(x-i)$ th, be that which it may. Consequently the $x-i-m+1$. . . $x-i-m+m-1$ are all Ys, $m-1$ in number, and the run will be accomplished in $i-m+1$ more throws, or at the $(x-m)$ th, if all these be Ys, of which the probability is q^{i-m+1} ; that is, the two events whose probabilities are P_m and q^{i-m+1} must happen consecutively to complete the *first* run at the $(x-m)$ th throw. Let z_p be the probability of the first run of i being completed at the p th throw; then will $P_m q^{i-m+1} = z_{x-m}$. Again, the probability of the succession above written by itself, and without reference to what precedes, is $(1-q) q^i$; but to make it the event in question, it must be preceded by one or other of the events whose probabilities are $P_1, P_2, P_3, \dots, P_i$; that one or other of these shall happen, the probability is $P_1 + P_2 + \dots + P_i$, and therefore that one or other of these shall happen, followed by the succession above written, the probability is $(P_1 + P_2 + \dots + P_i) (1-q) q^i$, which is also z_x . But

$$P_1 = z_{x-1} q^{-i} \quad P_2 = z_{x-2} q^{-i+1} \quad \dots \quad P_i = z_{x-i} q^{-1};$$

hence

$$z_x = (1-q) \cdot \{z_{x-1} + q z_{x-2} + q^2 z_{x-3} + \dots + q^{i-1} z_{x-i}\}.$$

After the i th throw, therefore, the probability required, z_x , is the coefficient of t^x in

$$\frac{\psi t}{1 - (1-q)(t + q t^2 + \dots + q^{i-1} t^i)}, \quad \text{or} \quad \frac{\psi t (1-q t)}{1 - q t - (1-q)(t - q^i t^{i+1})},$$

where ψt must be so taken that no term under t^i may appear, (the event cannot happen in less than i throws,) and that the coefficient of t^i may be q^i ; that is, ψt must be $q^i t^i$. If we then divide by $1-t$, the coefficient of t^x becomes $z_i + z_{i+1} + \dots + z_x$, which is the probability of having a run of i in x throws or less; that is, somewhere in x throws. Consequently, we must determine the coefficient of t^x in the development of

$$\frac{1}{1-t} \frac{q^i t^i (1-q t)}{1 - t + (1-q) q^i t^{i+1}},$$

$$\text{or} \quad \frac{1-q t}{(1-t)^2} q^i t^i - \frac{1-q t}{(1-t)^3} (1-q) q^{2i} t^{2i+1} + \frac{(1-q t)}{(1-t)^4} (1-q)^2 q^{3i} t^{3i+2} - \&c.,$$

the r th term (without its sign) being

$$\frac{(1-q t)^{r-1} t^{r-1}}{(1-t)^{r+1}} \times (1-q)^{r-1} q^{ri};$$

and the coefficient of t^x in the first factor is ($x =$ or $> ri + r - 1$),

$$\frac{[r+1, x-ri+1]}{[x-ri-r+1]} - q \frac{[r+1, x-ri]}{[x-ri-r]},$$

$$\text{or} \quad \frac{[r+1, x-ri]}{[x-ri-r+1]} \{x-ri+1 - q(x-ri-r+1)\}, \quad \text{or} \quad \frac{[x-ri-r+2, x-ri]}{[r]} \{(1-q)(x-ri-r+1) + r\}.$$

Multiply this by $(1-q)^{r-1} q^{ri}$, make $r=1, 2, \&c.$, and so on as long as x is greater than $ri + r - 1$, or up to $x=ri+r-1$; make the terms alternately positive and negative, and we have (settling the first term by itself, as before, and making $q'=1-q$.) for the probability required

$$q^i \{q'(x-i)+1\} - q^{2i} q' \frac{x-2i}{1 \cdot 2} \{q'(x-2i-1)+2\} \\ + q^{3i} q'^2 \frac{(x-3i-1)(x-3i)}{1 \cdot 2 \cdot 3} \{q'(x-3i-2)+3\} - \&c.$$

Let us suppose the number of throws to be $6=x$; the number in the run $2=i$; and the chances even, $q=q'=\frac{1}{2}$. We have then $6>3i-1$, or i must not exceed 2. Therefore the probability of having a run of 2 heads in six throws is

$$\frac{1}{4} \left(\frac{1}{2} \cdot 4 + 1 \right) - \frac{1}{16} \cdot \frac{1}{2} \cdot \frac{6-4}{2} \left(\frac{1}{2} \cdot 1 + 2 \right), \text{ or } \frac{3}{4} - \frac{5}{64}, \text{ or } \frac{43}{64}.$$

This may be easily verified, for the cases in which runs of two heads occur, are 1. Where the heads exceed the tails, or $1+6+\frac{6 \cdot 5}{2}$, or 22 cases. 2. Where there are 3 heads and 3 tails, $\frac{6 \cdot 5 \cdot 4}{2 \cdot 3}$, or 20 cases, excepting only HTHHT, THTHT, HTHTH, HTHTH, or 4 cases, remainder 16 cases. 3. Where there are 2 heads and 4 tails, in the cases HHTTTT, THHTT, &c., 5 cases; or $22+16+5$, or 43 cases out of 2^6 , that is, 43 out of 64.

Now comes this question: if two players, whose chances are as q and q' ($q+q'=1$), play on indefinitely, what is the highest run which the first is ever to expect in his favour? If we take out of the preceding the highest powers of x , and thus form the series to which the preceding perpetually approximates as x increases without limit, we find

$$q^i q' x - q^{2i} q'^2 \frac{x^2}{1 \cdot 2} + q^{3i} q'^3 \frac{x^3}{1 \cdot 2 \cdot 3} - \&c., \text{ or } 1 - \varepsilon^{-q^i q'^x}.$$

Consequently we have this singular result, that however much the chances may be in favour of one player, on a single game, so many games can be played that the odds shall be as great as we please to name, in favour of the one who has the smaller chance winning as many games following as we like to name, somewhere in the series.

We may also establish this result by returning to the generatrix of z_x ; or

$$\frac{q^i t^i (1-qt)}{1-t+(1-q)q^i t^{i+1}} = z_i t^i + z_{i+1} t^{i+1} + \dots$$

If we now suppose $t=1$, we have $1=z_i+z_{i+1}+\dots$ *ad inf.*, which verifies the preceding. But if we ask, in a very great number of throws, what are the runs for which the two have equal chances, we see, reversing q and q' , to obtain the chance of a run of i' , (which substitute for i), in favour of the other player, that we must have

$$1 - \varepsilon^{-q^{i'} q'^x} = 1 - \varepsilon^{-q^i q'^x}, \text{ or } q^i q' = q^{i'} q',$$

giving

$$\frac{i-1}{i'-1} = \frac{\log q'}{\log q}.$$

Thus if one player be nine times as skilful as another, $q'=\frac{9}{10}$, $q=\frac{1}{10}$, we have

$$\frac{i-1}{i'-1} = \frac{.954-1}{0-1} = .046, \text{ so that if } i=2, i'=22.+$$

Or a player nine times as skilful as another has a better chance (slightly) of winning 22 games running in a very large number than the other has of winning two games running.

(54.) PROBLEM. There is a lottery containing n numbers, $1, 2, 3, \dots, n$. Of these r are drawn at once, and then replaced. What is the probability that all the n numbers shall have been drawn in i drawings?

Let $z_{n,q}$ be the number of sets of i drawings, in which q and all under it can be drawn. It is evident that the number of sets of i which contain up to q fall short of the number which contain up to $q-1$ by a parcel of possible drawings, each of which contains up to $q-1$ without the appearance of q ; the latter being precisely the number of sets of i drawings of a lottery from which ticket q has been removed, and the problem altered from demanding $1 \dots q$ into $1 \dots q-1$. That is, the number of sets by which $z_{n,q}$ falls short of $z_{n,q-1}$ is $z_{n-1,q-1}$, or

$$z_{n,q} = z_{n,q-1} - z_{n-1,q-1} = \Delta z_{n-1,q-1},$$

where Δ refers to n . But by the same reasoning $z_{n-1,q-1} = \Delta z_{n-2,q-2}$, and so on, whence $z_{n,q} = \Delta^2 z_{n-2,q-2} = \dots = \Delta^i z_{n-q,0}$. The whole number of ways of drawing r out of $n-q$ is $[n-q, n-q-r+1] \div [r]$, and as i trials may combine these in any number of ways, we have the i th power of the preceding for the whole number of cases. And this itself is $z_{n-q,0}$, for the preceding must be interpreted as the number of sets of i drawings, in which all up to 0 appear, or the number of sets of i drawings without restriction. (This ought not to be perfectly satisfactory at first to a beginner; we leave it to him to furnish a method which contains no extension.) Consequently

$$z_{n,q} = \Delta^i \left(\frac{[n-q, n-q-r+1]}{[r]} \right)^i.$$

But the total number of sets of i drawings of r out of n is $\{[n, n-r+1] \div [r]\}^i$; whence the probability of all the q numbers coming out, as required in the enunciation, is

Theory of
Pro-
babilities.

$$\frac{\Delta^i([n-q, n-q-r+1])^i}{([n, n-r+1])^i}.$$

Theory of
Pro-
babilities.

To find the probability of all coming out, we must make $q=n$ in this result, which is, when developed,

$$1 - q \left(\frac{n-1}{n-r+1} \right)^i + q \frac{q-1}{2} \left(\frac{n-1}{n-r+1} \right)^i \left(\frac{n-2}{n-r} \right)^i - \dots \mp q \left(\frac{n-1}{n-r+1} \right)^i \dots \left(\frac{n-q+1}{n-q-r+3} \right)^i \pm \left(\frac{n-1}{n-r+1} \right)^i \dots \left(\frac{n-q}{n-q-r+2} \right)^i.$$

This formula is not easily applied, except in cases where no denominator becomes negative. But the preceding expression may be applied. For instance, required the probability of drawing all (q) out of four (n) in two (i) drawings of two (r) each. In the product whose difference is taken there are two (r) terms, and if we therefore begin forming products sufficient for the fourth difference, we have

$$\begin{array}{rcl} 4^2 \cdot 3^2 & = & 144 \\ 3^2 \cdot 2^2 & = & 36 \\ 2^2 \cdot 1^2 & = & 4 \\ 1^2 \cdot 0^2 & = & 0 \\ 0^2 \cdot (-1)^2 & = & 0 \end{array} \quad \begin{array}{rcl} 108 & 76 & 48 \\ 32 & 28 & 24 \\ 4 & 4 & 4 \\ 0 & 0 & 0 \end{array} \quad \frac{24}{144} = \frac{1}{6} \text{ prob. required.}$$

This may be verified as follows. The drawings of ABCD which favour the event are AB . CD, CD . AB, AC . BD, BD . AC, AD . BC, BC . AD, six in all; the total number of drawings is the square of the combinations of two out of four, or 36, and $\frac{6}{36}$ is $\frac{1}{6}$, as before.

(55.) All the formulæ to which we have hitherto been led are perplexing to calculate for moderate numbers, and absolutely out of the question for high numbers. We now come to the part of our subject which may be considered as the most important of the whole, being the most difficult of the indispensable considerations; namely, the approximation to functions of very high numbers. But we have first to consider the species of expressions which have been hitherto obtained. And here we cannot have avoided observing that in every case variable products have been obtained, in which one of the variables is the *number of factors*, which varies in a manner depending upon the number of events in question.

Now an event of any kind is not like a continuous magnitude, capable of division into parts which resemble each other and the whole, in every thing except size. All the parts of a line are complete in the possession of every property which belongs to the whole line; yet if three drawings of a lottery gave severally an inch, an inch, and half an inch, we could not, in common use of language, say that only two events and a half had happened, but *three* events, the third of which had a numerical accident of only half the magnitude of the first two. If we look at the word *individuality*, the same in etymology as *indivisibility*, we may trace to the notion above given the foundation of our way of making a general word which shall express a collection of circumstances or properties, as making a whole distinct from other wholes of the same kind. And because we say the first event, or the second event, &c., we are not therefore to talk of fractions of events; for it will be readily seen that there are here *pronouns of succession*, rather than numeral nouns. *One* as distinguished from *another*, is not the same as *one* as distinguished from *one* and *one* put together. The first is only *this*, as distinguished from *that*; or the *first* as distinguished from the *second*. Now *first*, *second*, *third*, &c. are really pronouns,* whatever grammarians may say to the contrary; that is, they are referable to the same class as *this*, *that*, and *the other*; and they do not admit ideas of partition.

We cannot, therefore, speak of $2\frac{1}{2}$ events, except by an extension, which, though perceptible enough in itself, will not be any guide to proper deductions. The product $1 \cdot 2 \cdot 3 \dots x$, when x is a whole number, is readily understood; but what is its meaning when x is $3\frac{1}{2}$? Is it $1 \cdot 2 \cdot 3 \cdot 3\frac{1}{2}$? We shall show that by laying down this definition we do not get a continuous function of x . Let α be a small fraction; and suppose $[3-\alpha]$ means $1 \cdot 2 \cdot (3-\alpha)$, while $[3+\alpha]$ means $1 \cdot 2 \cdot 3 (3+\alpha)$. Therefore

$$\frac{[3+\alpha]}{[3-\alpha]} = \frac{3(3+\alpha)}{3-\alpha},$$

and when $\alpha=0$, $1=3$, which shows that $[3+\alpha]$, &c., as thus defined, cannot have the properties of a continuous algebraical function. We now ask this question: What is that function of x , which, whenever x is a whole number, reduces itself to $1 \cdot 2 \cdot 3 \dots x$, and which varies continuously from $1 \cdot 2 \cdot 3 \dots n$ to $1 \cdot 2 \cdot 3 \dots n+1$, when x varies continuously from n to $n+1$?
